Table of Contents

What is Amazon RDS?	1
Overview	1
DB instances	1
AWS Regions and Availability Zones	2
Security	2
Monitoring an Amazon RDS DB instance	3
How to work with Amazon RDS	3
AWS Management Console	3
Command line interface	3
Programming with Amazon RDS	3
How you are charged for Amazon RDS	3
What's next?	3
Getting started	4
Database engine-Specific topics	4
DB instances	5
DB instance classes	7
DB instance class types	7
Supported DB engines	8
Determining DB instance class support in AWS Regions	17
Changing your DB instance class	20
Configuring the processor	20
Hardware specifications	33
DB instance storage	40
Storage types	40
General Purpose SSD storage	40
Provisioned IOPS storage	42
Magnetic storage	44
Monitoring storage performance	44
Factors that affect storage performance	45
Regions, Availability Zones, and Local Zones	49
AWS Regions	49
Availability Zones	52
Local Zones	52
High availability (Multi-AZ)	53
Modifying a DB instance to be a Multi-AZ deployment	54
Failover process for Amazon RDS	54
DB instance billing for Amazon RDS	57
On-Demand DB instances	58
Reserved DB instances	59
Setting up	67
Sign up for AWS	67
Create an IAM user	67
Determine requirements	69
Provide access to your DB instance in your VPC by creating a security group	70
Getting started	73
Creating a MariaDB DB instance and connecting to a database	73
Creating a MariaDB DB instance	73
Connecting to a database on a DB instance running MariaDB	77
Deleting a DB instance	79
Creating a SQL Server DB instance and connecting to it	80
Creating a sample SQL Server DB instance	80
Connecting to your sample DB instance	83
Exploring your sample DB instance	84
Deleting your sample DB instance	85

Creating a MySQL DB instance and connecting to a database	86
Creating a MySQL DB instance	86
Connecting to a database on a DB instance running MySQL	90
Deleting a DB instance	92
Creating an Oracle DB instance and connecting to a database	93
Creating a sample Oracle DB instance	93
Connecting to your sample DB instance	97
Deleting your sample DB instance	99
Creating a PostgreSQL DB instance and connecting to a database	99
Creating a PostgreSQL DB instance	99
Connecting to a PostgreSQL DB instance	103
Deleting a DB instance	107
Tutorial: Create a web server and an Amazon RDS DB instance	108
Create a DB instance	109
Create a web server	114
Tutorials	126
Tutorials in this guide	126
Tutorials in other AWS guides	126
Best practices for Amazon RDS	128
Amazon RDS basic operational guidelines	128
DB instance RAM recommendations	129
Using Enhanced Monitoring to identify operating system issues	129
Using metrics to identify performance issues	129
Viewing performance metrics	129
Evaluating performance metrics	132
Tuning queries	133
Best practices for working with MySQL storage engines	134
Table size	134
Number of tables	134
Storage engine	135
Best practices for working with MariaDB storage engines	135
Table size	135
Number of tables	136
Storage engine	136
Best practices for working with Oracle	137
Best practices for working with PostgreSQL	137
Loading data into a PostgreSQL DB instance	137
Working with the PostgreSQL autovacuum feature	137
Best practices for working with SQL Server	138
Amazon RDS for SQL Server best practices video	139
Working with DB parameter groups	139
Amazon RDS new features and best practices presentation video	139
Configuring a DB instance	140
Creating a DB instance	141
Available settings	145
Original console example	157
Connecting to a DB instance	162
Finding the connection information	162
Database authentication options	165
Encrypted connections	166
Scenarios for accessing a DB instance	166
Connecting to a DB instance running a specific DB engine	166
Managing connections with RDS Proxy	167
Managing connections with RDS Proxy	167
Working with option groups	212
Option groups overview	212
Creating an option group	214

Copying an option group	215
Adding an option to an option group	216
Listing the options and option settings for an option group	220
Modifying an option setting	221
Removing an option from an option group	224
Deleting an option group	225
Working with parameter groups	228
Creating a DB parameter group	229
Associating a DB parameter group with a DB instance	231
Modifying parameters in a DB parameter group	232
Resetting parameters in a DB parameter group	234
Copying a DB parameter group	236
Listing DB parameter groups	238
Viewing parameter values for a DB parameter group	239
Comparing DB parameter groups	240
Specifying DB parameters	240
Managing a DB instance	245
Stopping a DB instance	246
Benefits	246
Limitations	247
Option and parameter group considerations	247
Public IP address	247
Stopping a DB instance	247
Starting a DB instance	249
Modifying a DB instance	250
Apply Immediately setting	251
Available settings	251
Maintaining a DB instance	264
Applying updates	266
Maintenance for Multi-AZ deployments	267
The maintenance window	268
Adjusting the maintenance window for a DB instance	269
Upgrading the engine version	271
Manually upgrading the engine version	271
Automatically upgrading the minor engine version	273
Renaming a DB instance	274
Renaming to replace an existing DB instance	274
Rebooting a DB instance	276
Working with read replicas	278
Overview	280
Creating a read replica	283
Promoting a read replica	285
Monitoring read replication	288
Creating a read replica in a different AWS Region	290
Tagging RDS resources	299
Overview	299
Using tags for access control with IAM	300
Using tags to produce detailed billing reports	300
Adding, listing, and removing tags	300
Using the AWS Tag Editor	303
Copying tags to DB instance snapshots	303
Tutorial: Use tags to specify which DB instances to stop	304
Enabling backups	306
Working with ARNs	309
Constructing an ARN	309
Getting an existing ARN	312
Working with storage	316

Increasing DB instance storage capacity	316
Managing capacity automatically with storage autoscaling	317
Modifying Provisioned IOPS	322
Deleting a DB instance	324
Deletion protection	324
Final snapshots and retained backups	324
Deleting a DB instance	325
Backing up and restoring a DB instance	327
Working with backups	328
Backup storage	328
Backup window	328
Backup retention period	330
Enabling automated backups	330
Retaining automated backups	331
Deleting retained automated backups	333
Disabling automated backups	334
Using AWS Backup	335
Unsupported MySQL storage engines	336
Unsupported MariaDB storage engines	336
Replicating automated backups to another Region	338
Enabling cross-Region automated backups	338
Finding information about replicated backups	339
Point-in-time recovery from a replicated backup	342
Stopping backup replication	343
Deleting replicated backups	344
.....	345
Creating a DB snapshot	346
Restoring from a DB snapshot	349
Parameter groups	349
Security groups	349
Option groups	349
Microsoft SQL Server	350
Oracle	350
Restoring from a snapshot	350
Copying a snapshot	352
Limitations	352
Snapshot retention	352
Copying shared snapshots	352
Handling encryption	353
Incremental snapshot copying	353
Cross-Region copying	353
Option groups	356
Parameter groups	357
Copying a DB snapshot	357
Sharing a snapshot	365
Sharing an encrypted snapshot	366
Sharing a snapshot	368
Exporting snapshot data to Amazon S3	373
Limitations	374
Overview of exporting snapshot data	374
Setting up access to an S3 bucket	374
Exporting a snapshot to an S3 bucket	377
Monitoring snapshot exports	379
Canceling a snapshot export	380
Troubleshooting PostgreSQL permissions errors	381
File naming convention	382
Data conversion	382

Point-in-time recovery	389
Deleting a snapshot	392
Deleting a DB snapshot	392
Tutorial: Restore a DB instance from a DB snapshot	394
Prerequisites for restoring a DB instance from a DB snapshot	394
Restoring a DB instance from a DB snapshot	395
Modifying a restored DB instance	396
Monitoring a DB instance	399
Overview of monitoring	400
Monitoring plan	400
Performance baseline	400
Performance guidelines	400
Monitoring tools	401
DB instance status	404
Using Amazon RDS recommendations	407
Responding to recommendations	409
Using Performance Insights	412
Overview	412
Enabling and Disabling Performance Insights	415
Accessing Performance Insights	419
Monitoring with the Performance Insights dashboard	421
Customizing the Performance Insights dashboard	444
Retrieving data with the Performance Insights API	454
Metrics published to CloudWatch	467
Logging Performance Insights calls by using AWS CloudTrail	468
Using Enhanced Monitoring	471
Enhanced Monitoring availability	471
Differences between CloudWatch and Enhanced Monitoring metrics	471
Setting up and enabling Enhanced Monitoring	471
Viewing Enhanced Monitoring	474
Viewing Enhanced Monitoring by using CloudWatch Logs	478
Using Amazon RDS event notification	487
Amazon RDS event categories and event messages	488
Subscribing to Amazon RDS event notification	494
Listing Amazon RDS event notification subscriptions	496
Modifying an Amazon RDS event notification subscription	497
Adding a source identifier to an Amazon RDS event notification subscription	499
Removing a source identifier from an Amazon RDS event notification subscription	500
Listing the Amazon RDS event notification categories	501
Deleting an Amazon RDS event notification subscription	502
Viewing Amazon RDS events	503
.....	503
Accessing database logs	504
Viewing and listing database log files	504
Downloading a database log file	504
Watching a database log file	506
Publishing to CloudWatch Logs	506
Reading log file contents using REST	506
MariaDB database log files	508
Microsoft SQL Server database log files	516
MySQL database log files	519
Oracle database log files	527
PostgreSQL database log files	534
Monitoring RDS with CloudWatch	540
Amazon RDS metrics	541
Amazon RDS dimensions	544
Viewing metrics and dimensions	544

Creating alarms	546
Publishing to CloudWatch Logs	547
Configuring CloudWatch log integration	547
Viewing DB instance metrics	548
Getting CloudWatch and EventBridge events for RDS	551
Overview of events for Amazon RDS	551
Creating rules to send Amazon RDS events to CloudWatch Events	553
Tutorial: Log Amazon RDS instance states	554
Working with AWS CloudTrail and Amazon RDS	557
CloudTrail integration with Amazon RDS	557
Amazon RDS log file entries	557
Working with RDS on AWS Outposts	561
Prerequisites	561
Support for Amazon RDS features	562
Supported DB instance classes	564
Customer-owned IP addresses	565
Creating DB instances	567
MariaDB on Amazon RDS	574
Common management tasks	574
MariaDB versions	576
Deprecation of MariaDB versions 10.0 and 10.1	577
MariaDB feature support	578
MariaDB 10.5 support	578
MariaDB 10.4 support	579
MariaDB 10.3 support	579
MariaDB 10.2 support	579
MariaDB 10.1 support	580
MariaDB 10.0 support	580
Features not supported	580
Supported storage engines	581
File size limits	581
MariaDB security	582
SSL support	584
Cache warming	585
Dumping and loading the buffer pool on demand	586
Database parameters	586
Common DBA tasks	586
Local time zone	587
Connecting to a DB instance running MariaDB	588
Finding the connection information	589
Connecting from the mysql utility	591
Connecting with SSL	592
Troubleshooting	592
Updating applications for new SSL/TLS certificates	594
Determining whether a client requires certificate verification in order to connect	594
Updating your application trust store	595
Example Java code for establishing SSL connections	597
Upgrading the MariaDB DB engine	598
Overview	598
Major version upgrades	599
Upgrading a MariaDB DB instance	600
Automatic minor version upgrades	600
Migrating data from a MySQL DB snapshot to a MariaDB DB instance	603
Incompatibilities between MariaDB and MySQL	603
Performing the migration	603
Working with MariaDB replication	605
Working with MariaDB read replicas	605

Configuring GTID-based replication	613
Importing data into a MariaDB DB instance	616
Options for MariaDB	616
MariaDB Audit Plugin support	617
Parameters for MariaDB	620
MariaDB on Amazon RDS SQL reference	625
mysql.rds_replica_status	625
mysql.rds_set_external_master_gtid	626
mysql.rds_kill_query_id	628
Microsoft SQL Server on Amazon RDS	630
Common management tasks	630
Limits	632
DB instance class support	634
Security	635
Compliance programs	636
HIPAA	636
SSL support	637
Version support	637
Version management	639
Database engine patches and versions	639
Deprecation schedule	639
Feature support	640
SQL Server 2019 features	640
SQL Server 2017 features	640
SQL Server 2016 features	641
SQL Server 2014 features	641
SQL Server 2012 features	641
SQL Server 2008 R2 deprecated on Amazon RDS	642
CDC support	642
Features not supported and features with limited support	643
Multi-AZ deployments	643
Using TDE	644
Functions and stored procedures	644
Local time zone	646
Supported time zones	647
Licensing SQL Server on Amazon RDS	655
Restoring license-terminated DB instances	655
SQL Server Developer Edition	655
Connecting to a DB instance running SQL Server	656
Connecting to your DB instance with SSMS	656
Connecting to your DB instance with SQL Workbench/J	658
Security group considerations	660
Troubleshooting	661
Updating applications for new SSL/TLS certificates	662
Determining whether any applications are connecting to your Microsoft SQL Server DB instance using SSL	662
Determining whether a client requires certificate verification in order to connect	663
Updating your application trust store	664
Upgrading the SQL Server DB engine	666
Overview	666
Major version upgrades	667
Multi-AZ and in-memory optimization considerations	668
Option and parameter group considerations	668
Testing an upgrade	669
Upgrading a SQL server DB instance	669
Upgrading deprecated DB instances before support ends	670
Importing and exporting SQL Server databases	671

Limitations and recommendations	671
Setting up	672
Using native backup and restore	675
Compressing backup files	685
Troubleshooting	685
.....	686
Importing and exporting SQL Server data using other methods	687
Working with SQL Server read replicas	696
Configuring read replicas for SQL Server	696
Read replica limitations with SQL Server	696
Troubleshooting a SQL Server read replica problem	697
Multi-AZ for SQL Server	698
Adding Multi-AZ to a SQL Server DB instance	699
Notes and recommendations	699
Determining the location of the secondary	701
Migrating to always on AGs	702
Additional features for SQL Server	703
Using SSL with a SQL Server DB instance	704
Configuring security protocols and ciphers	707
Using Windows Authentication with a SQL Server DB instance	711
Amazon S3 integration	721
Using Database Mail	734
Instance store support for tempdb	744
Using extended events	746
Options for SQL Server	749
Listing the available options for SQL Server versions and editions	750
Native backup and restore	751
Transparent Data Encryption	754
SQL Server Audit	757
SQL Server Analysis Services	762
SQL Server Integration Services	773
SQL Server Reporting Services	787
Microsoft Distributed Transaction Coordinator	797
Common DBA tasks for SQL Server	809
Accessing the tempdb database	810
Analyzing your database workload with SQL Server Tuning Advisor	812
Collations and character sets	814
Determining a recovery model	817
Determining the last failover time	817
Disabling fast inserts	818
Dropping a SQL Server database	818
Renaming a Multi-AZ database	818
Resetting the db_owner role password	819
Restoring license-terminated DB instances	819
Transitioning a database from OFFLINE to ONLINE	820
Using CDC	820
Using SQL Server Agent	822
Working with SQL Server logs	823
Working with trace and dump files	824
MySQL on Amazon RDS	826
Common management tasks	826
MySQL versions	828
Deprecation of MySQL version 5.6	830
Deprecation of MySQL version 5.5	831
MySQL features not supported by Amazon RDS	832
Supported storage engines	832
MySQL security	833

Password Validation Plugin	834
SSL support	835
Using memcached and other options with MySQL	836
InnoDB cache warming	837
Dumping and loading the buffer pool on demand	837
Local time zone	838
Known issues and limitations	839
Deprecated MySQL versions	839
Connecting to a DB instance running MySQL	840
Finding the connection information	840
Connecting from the MySQL client	843
Connecting with SSL	844
Connecting from MySQL Workbench	844
Troubleshooting	846
Updating applications for new SSL/TLS certificates	848
Determining whether any applications are connecting to your MySQL DB instance using SSL	849
Determining whether a client requires certificate verification to connect	849
Updating your application trust store	850
Example Java code for establishing SSL connections	851
Upgrading the MySQL DB engine	853
Overview	853
Major version upgrades	854
Testing an upgrade	858
Upgrading a MySQL DB instance	858
Automatic minor version upgrades	858
Upgrading with reduced downtime	860
Upgrading a MySQL DB snapshot	863
Importing data into a MySQL DB instance	865
Overview	865
Importing data considerations	866
Restoring a backup into an Amazon RDS MySQL DB instance	871
Importing data from a MySQL or MariaDB DB to a MySQL or MariaDB DB instance	879
Importing data to an Amazon RDS MySQL or MariaDB DB instance with reduced downtime	881
Importing data from any source to a MySQL or MariaDB DB instance	894
Working with MySQL replication	899
Working with MySQL read replicas	899
Using GTID-based replication	910
Replication with a MySQL or MariaDB instance running external to Amazon RDS	914
Exporting data from a MySQL DB instance	921
Prepare an external MySQL database	921
Prepare the source MySQL DB instance	922
Copy the database	923
Complete the export	924
Options for MySQL	925
MariaDB Audit Plugin	926
memcached	929
Common DBA tasks for MySQL	933
Ending a session or query	933
Skipping the current replication error	933
Working with InnoDB tablespaces to improve crash recovery times	934
Managing the global status history	936
Using Kerberos authentication for MySQL	938
Setting up Kerberos authentication for MySQL DB instances	939
Managing a DB instance in a domain	945
Connecting to MySQL with Kerberos authentication	946
Restoring a MySQL DB instance and adding it to a domain	947
Kerberos authentication MySQL limitations	947

Known issues and limitations	948
Inconsistent InnoDB buffer pool size	948
Index merge optimization returns wrong results	948
Log file size	949
MySQL parameter exceptions for Amazon RDS DB instances	949
MySQL file size limits in Amazon RDS	950
MySQL Keyring Plugin not supported	951
MySQL on Amazon RDS SQL reference	952
Overview	952
SQL reference conventions	953
mysql.rds_set_master_auto_position	953
mysql.rds_set_external_master	954
mysql.rds_set_external_master_with_delay	956
mysql.rds_set_external_master_with_auto_position	959

What is Amazon Relational Database Service (Amazon RDS)?

Amazon Relational Database Service (Amazon RDS) is a web service that makes it easier to set up, operate, and scale a relational database in the AWS Cloud. It provides cost-efficient, resizable capacity for an industry-standard relational database and manages common database administration tasks.

Note

This guide covers Amazon RDS database engines other than Amazon Aurora. For information about using Amazon Aurora, see the [Amazon Aurora User Guide](#).

This guide covers using Amazon RDS in the AWS Cloud. For information about using Amazon RDS in on-premises VMware environments, see the [Amazon RDS on VMware User Guide](#).

Overview of Amazon RDS

Why do you want a managed relational database service? Because Amazon RDS takes over many of the difficult and tedious management tasks of a relational database:

- When you buy a server, you get CPU, memory, storage, and IOPS, all bundled together. With Amazon RDS, these are split apart so that you can scale them independently. If you need more CPU, less IOPS, or more storage, you can easily allocate them.
- Amazon RDS manages backups, software patching, automatic failure detection, and recovery.
- To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that require advanced privileges.
- You can have automated backups performed when you need them, or manually create your own backup snapshot. You can use these backups to restore a database. The Amazon RDS restore process works reliably and efficiently.
- You can use the database products you are already familiar with: MySQL, MariaDB, PostgreSQL, Oracle, Microsoft SQL Server.
- You can get high availability with a primary instance and a synchronous secondary instance that you can fail over to when problems occur. You can also use MariaDB, Microsoft SQL Server, MySQL, Oracle, and PostgreSQL read replicas to increase read scaling.
- In addition to the security in your database package, you can help control who can access your RDS databases by using AWS Identity and Access Management (IAM) to define users and permissions. You can also help protect your databases by putting them in a virtual private cloud.

If you are new to AWS products and services, begin learning more with the following resources:

- For an overview of all AWS products, see [What is cloud computing?](#)
- Amazon Web Services provides a number of database services. For guidance on which service is best for your environment, see [Running databases on AWS](#).

DB instances

The basic building block of Amazon RDS is the DB instance. A *DB instance* is an isolated database environment in the AWS Cloud. Your DB instance can contain multiple user-created databases. You can access your DB instance by using the same tools and applications that you use with a standalone

database instance. You can create and modify a DB instance by using the AWS Command Line Interface, the Amazon RDS API, or the AWS Management Console.

Each DB instance runs a *DB engine*. Amazon RDS currently supports the MySQL, MariaDB, PostgreSQL, Oracle, and Microsoft SQL Server DB engines. Each DB engine has its own supported features, and each version of a DB engine may include specific features. Additionally, each DB engine has a set of parameters in a DB parameter group that control the behavior of the databases that it manages.

The computation and memory capacity of a DB instance is determined by its *DB instance class*. You can select the DB instance that best meets your needs. If your needs change over time, you can change DB instances. For information, see [DB instance classes \(p. 7\)](#).

Note

For pricing information on DB instance classes, see the Pricing section of the [Amazon RDS](#) product page.

DB instance storage comes in three types: Magnetic, General Purpose (SSD), and Provisioned IOPS (PIOPS). They differ in performance characteristics and price, allowing you to tailor your storage performance and cost to the needs of your database. Each DB instance has minimum and maximum storage requirements depending on the storage type and the database engine it supports. It's important to have sufficient storage so that your databases have room to grow. Also, sufficient storage makes sure that features for the DB engine have room to write content or log entries. For more information, see [Amazon RDS DB instance storage \(p. 40\)](#).

You can run a DB instance on a virtual private cloud (VPC) using the Amazon Virtual Private Cloud (Amazon VPC) service. When you use a VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists. The basic functionality of Amazon RDS is the same whether it's running in a VPC or not. Amazon RDS manages backups, software patching, automatic failure detection, and recovery. There's no additional cost to run your DB instance in a VPC. For more information on using Amazon VPC with RDS, see [Amazon Virtual Private Cloud VPCs and Amazon RDS \(p. 1718\)](#).

Amazon RDS uses Network Time Protocol (NTP) to synchronize the time on DB Instances.

AWS Regions and Availability Zones

Amazon cloud computing resources are housed in highly available data center facilities in different areas of the world (for example, North America, Europe, or Asia). Each data center location is called an AWS Region.

Each AWS Region contains multiple distinct locations called Availability Zones, or AZs. Each Availability Zone is engineered to be isolated from failures in other Availability Zones. Each is engineered to provide inexpensive, low-latency network connectivity to other Availability Zones in the same AWS Region. By launching instances in separate Availability Zones, you can protect your applications from the failure of a single location. For more information, see [Regions, Availability Zones, and Local Zones \(p. 49\)](#).

You can run your DB instance in several Availability Zones, an option called a Multi-AZ deployment. When you choose this option, Amazon automatically provisions and maintains a secondary standby DB instance in a different Availability Zone. Your primary DB instance is synchronously replicated across Availability Zones to the secondary instance. This approach helps provide data redundancy and failover support, eliminate I/O freezes, and minimize latency spikes during system backups. For more information, see [High availability \(Multi-AZ\) for Amazon RDS \(p. 53\)](#).

Security

A *security group* controls the access to a DB instance. It does so by allowing access to IP address ranges or Amazon EC2 instances that you specify.

For more information about security groups, see [Security in Amazon RDS \(p. 1627\)](#).

Monitoring an Amazon RDS DB instance

There are several ways that you can track the performance and health of a DB instance. You can use the Amazon CloudWatch service to monitor the performance and health of a DB instance. CloudWatch performance charts are shown in the Amazon RDS console. You can also subscribe to Amazon RDS events to be notified about changes to a DB instance, DB snapshot, DB parameter group, or DB security group. For more information, see [Monitoring an Amazon RDS DB instance \(p. 399\)](#).

How to work with Amazon RDS

There are several ways that you can interact with Amazon RDS.

AWS Management Console

The AWS Management Console is a simple web-based user interface. You can manage your DB instances from the console with no programming required. To access the Amazon RDS console, sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

Command line interface

You can use the AWS Command Line Interface (AWS CLI) to access the Amazon RDS API interactively. To install the AWS CLI, see [Installing the AWS Command Line Interface](#). To begin using the AWS CLI for RDS, see [AWS Command Line Interface reference for Amazon RDS](#).

Programming with Amazon RDS

If you are a developer, you can access the Amazon RDS programmatically. For more information, see [Amazon RDS application programming interface \(API\) reference \(p. 1759\)](#).

For application development, we recommend that you use one of the AWS Software Development Kits (SDKs). The AWS SDKs handle low-level details such as authentication, retry logic, and error handling, so that you can focus on your application logic. AWS SDKs are available for a wide variety of languages. For more information, see [Tools for Amazon web services](#).

AWS also provides libraries, sample code, tutorials, and other resources to help you get started more easily. For more information, see [Sample code & libraries](#).

How you are charged for Amazon RDS

When you use Amazon RDS, you can choose to use on-demand DB instances or reserved DB instances. For more information, see [DB instance billing for Amazon RDS \(p. 57\)](#).

For Amazon RDS pricing information, see the [Amazon RDS product page](#).

What's next?

The preceding section introduced you to the basic infrastructure components that RDS offers. What should you do next?

Getting started

Create a DB instance using instructions in [Getting started with Amazon RDS \(p. 73\)](#).

Database engine–Specific topics

You can review information specific to a particular DB engine in the following sections:

- [MariaDB on Amazon RDS \(p. 574\)](#)
- [Microsoft SQL Server on Amazon RDS \(p. 630\)](#)
- [MySQL on Amazon RDS \(p. 826\)](#)
- [Oracle on Amazon RDS \(p. 979\)](#)
- [PostgreSQL on Amazon RDS \(p. 1453\)](#)

Amazon RDS DB instances

A *DB instance* is an isolated database environment running in the cloud. It is the basic building block of Amazon RDS. A DB instance can contain multiple user-created databases, and can be accessed using the same client tools and applications you might use to access a standalone database instance. DB instances are simple to create and modify with the Amazon AWS command line tools, Amazon RDS API operations, or the AWS Management Console.

Note

Amazon RDS supports access to databases using any standard SQL client application. Amazon RDS does not allow direct host access.

You can have up to 40 Amazon RDS DB instances, with the following limitations:

- 10 for each SQL Server edition (Enterprise, Standard, Web, and Express) under the "license-included" model
- 10 for Oracle under the "license-included" model
- 40 for MySQL, MariaDB, or PostgreSQL
- 40 for Oracle under the "bring-your-own-license" (BYOL) licensing model

Note

If your application requires more DB instances, you can request additional DB instances by using [this form](#).

Each DB instance has a DB instance identifier. This customer-supplied name uniquely identifies the DB instance when interacting with the Amazon RDS API and AWS CLI commands. The DB instance identifier must be unique for that customer in an AWS Region.

The identifier is used as part of the DNS hostname allocated to your instance by RDS. For example, if you specify db1 as the DB instance identifier, then RDS will automatically allocate a DNS endpoint for your instance, such as db1.123456789012.us-east-1.rds.amazonaws.com, where 123456789012 is the fixed identifier for a specific region for your account.

Each DB instance supports a database engine. Amazon RDS currently supports MySQL, MariaDB, PostgreSQL, Oracle, Microsoft SQL Server, and Amazon Aurora database engines.

When creating a DB instance, some database engines require that a database name be specified. A DB instance can host multiple databases, or a single Oracle database with multiple schemas. The database name value depends on the database engine:

- For the MySQL and MariaDB database engines, the database name is the name of a database hosted in your DB instance. Databases hosted by the same DB instance must have a unique name within that instance.
- For the Oracle database engine, database name is used to set the value of ORACLE_SID, which must be supplied when connecting to the Oracle RDS instance.
- For the Microsoft SQL Server database engine, database name is not a supported parameter.
- For the PostgreSQL database engine, the database name is the name of a database hosted in your DB instance. A database name is not required when creating a DB instance. Databases hosted by the same DB instance must have a unique name within that instance.

Amazon RDS creates a master user account for your DB instance as part of the creation process. This master user has permissions to create databases and to perform create, delete, select, update, and insert operations on tables the master user creates. You must set the master user password when you create a DB instance, but you can change it at any time using the Amazon AWS command line tools, Amazon RDS

API operations, or the AWS Management Console. You can also change the master user password and manage users using standard SQL commands.

Note

This guide covers non-Aurora Amazon RDS database engines. For information about using Amazon Aurora, see the [Amazon Aurora User Guide](#).

DB instance classes

The DB instance class determines the computation and memory capacity of an Amazon RDS DB instance. The DB instance class you need depends on your processing power and memory requirements.

For more information about instance class pricing, see [Amazon RDS pricing](#).

Topics

- [DB instance class types \(p. 7\)](#)
- [Supported DB engines for DB instance classes \(p. 8\)](#)
- [Determining DB instance class support in AWS Regions \(p. 17\)](#)
- [Changing your DB instance class \(p. 20\)](#)
- [Configuring the processor for a DB instance class \(p. 20\)](#)
- [Hardware specifications for DB instance classes \(p. 33\)](#)

DB instance class types

Amazon RDS supports three types of instance classes: Standard, Memory Optimized, and Burstable Performance. For more information about Amazon EC2 instance types, see [Instance type](#) in the Amazon EC2 documentation.

The following are the Standard DB instance classes available:

- **db.m6g** – General-purpose instance classes powered by AWS Graviton2 processors. These deliver balanced compute, memory, and networking for a broad range of general purpose workloads.

You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors by completing the same steps as any other DB instance modification.
- **db.m5d** – Newest generation instance classes that are optimized for low latency, very high random I/O performance, and high sequential read throughput.
- **db.m5** – Latest generation general-purpose instance classes that provide a balance of compute, memory, and network resources, and are a good choice for many applications. The db.m5 instance classes provide more computing capacity than the previous db.m4 instance classes. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor.
- **db.m4** – General-purpose instance classes that provide more computing capacity than the previous db.m3 instance classes.
- **db.m3** – General-purpose instance classes that provide more computing capacity than the previous db.m1 instance classes.
- **db.m1** – Earlier generation general-purpose instance classes.

The following are the Memory Optimized DB instance classes available:

- **db.z1d** – Instance classes optimized for memory-intensive applications. These offer both high compute capacity and a high memory footprint. High frequency z1d instances deliver a sustained all core frequency of up to 4.0 GHz.
- **db.x1e** – Instance classes optimized for memory-intensive applications. These offer one of the lowest price per gibibyte (GiB) of RAM among the DB instance classes and up to 3,904 GiB of DRAM-based instance memory.
- **db.x1** – Instance classes optimized for memory-intensive applications. These offer one of the lowest price per GiB of RAM among the DB instance classes and up to 1,952 GiB of DRAM-based instance memory.

- **db.r6g** – Instance classes powered by AWS Graviton2 processors. These are ideal for running memory-intensive workloads in open-source databases such as MySQL and PostgreSQL.

You can modify a DB instance to use one of the DB instance classes powered by AWS Graviton2 processors by completing the same steps as any other DB instance modification.

- **db.r5b** – Instance classes that are memory-optimized for throughput-intensive applications. Powered by the AWS Nitro System, db.r5b instances deliver up to 60 Gbps bandwidth and 260,000 IOPS of EBS performance, which is the fastest block storage performance on EC2.
- **db.r5d** – Instance classes that are optimized for low latency, very high random I/O performance, and high sequential read throughput.
- **db.r5** – Latest generation instance classes optimized for memory-intensive applications. These offer improved networking and Amazon Elastic Block Store (Amazon EBS) performance. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor.
- **db.r4** – Instance classes optimized for memory-intensive applications. These offer improved networking and Amazon EBS performance.
- **db.r3** – Instance classes that provide memory optimization.
- **db.m2** – Earlier generation memory-optimized instance classes.

The following are the Burstable Performance DB instance classes available:

- **db.t3** – Next generation instance classes that provide a baseline performance level, with the ability to burst to full CPU usage. These instance classes provide more computing capacity than the previous db.t2 instance classes. They are powered by the AWS Nitro System, a combination of dedicated hardware and lightweight hypervisor.
- **db.t2** – Instance classes that provide a baseline performance level, with the ability to burst to full CPU usage.

Note

The DB instance classes that use the AWS Nitro System (db.m5, db.r5, db.t3) are throttled on combined read plus write workload.

For DB instance class hardware specifications, see [Hardware specifications for DB instance classes \(p. 33\)](#).

Supported DB engines for DB instance classes

The following are DB engine considerations for DB instance classes:

MariaDB

The Graviton2 instance classes db.m6g and db.r6g are supported for all MariaDB 10.5 versions and MariaDB version 10.4.13 and higher 10.4 versions.

Microsoft SQL Server

Instance class support varies according to the version and edition of SQL Server. For instance class support by version and edition, see [DB instance class support for Microsoft SQL Server \(p. 634\)](#).

MySQL

The Graviton2 instance classes db.m6g and db.r6g are supported for RDS for MySQL versions 8.0.17 and higher.

Oracle

Instance class support varies according to the version and edition of Oracle. For instance class support by version and edition, see [RDS for Oracle instance classes \(p. 992\)](#).

PostgreSQL

PostgreSQL versions 13 and higher support the db.m6g, db.m5, db.r6g, db.r5, db.t3 instance classes. Previous generations of classes are supported only by PostgreSQL versions lower than 13 and include db.m4, db.m3, db.r4, db.r3, and db.t2.

In the following table, you can find details about supported Amazon RDS DB instance classes for each Amazon RDS DB engine.

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
db.m6g – Standard instance classes powered by AWS Graviton2 processors					
db.m6g.16xlarge	All MariaDB 10.5 versions and MariaDB version 10.4.13 & higher 10.4 versions	No	MySQL 8.0.17 & higher	No	PostgreSQL 13,12.3 & higher
db.m6g.12xlarge	All MariaDB 10.5 versions and MariaDB version 10.4.13 & higher 10.4 versions	No	MySQL 8.0.17 & higher	No	PostgreSQL 13,12.3 & higher
db.m6g.8xlarge	All MariaDB 10.5 versions and MariaDB version 10.4.13 & higher 10.4 versions	No	MySQL 8.0.17 & higher	No	PostgreSQL 13,12.3 & higher
db.m6g.4xlarge	All MariaDB 10.5 versions and MariaDB version 10.4.13 & higher 10.4 versions	No	MySQL 8.0.17 & higher	No	PostgreSQL 13,12.3 & higher
db.m6g.2xlarge	All MariaDB 10.5 versions and MariaDB version 10.4.13 & higher 10.4 versions	No	MySQL 8.0.17 & higher	No	PostgreSQL 13,12.3 & higher
db.m6g.xlarge	All MariaDB 10.5 versions and MariaDB version	No	MySQL 8.0.17 & higher	No	PostgreSQL 13,12.3 & higher

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
	10.4.13 & higher 10.4 versions

Determining DB instance class support in AWS Regions

To determine the DB instance classes supported by each DB engine in a specific AWS Region, you can use the AWS Management Console, the [Amazon RDS Pricing](#) page, or the `describe-orderable-db-instance-options` command for the AWS Command Line Interface (AWS CLI).

Note

When you perform operations with the AWS CLI, such as creating or modifying a DB instance, it automatically shows the supported DB instance classes for a specific DB engine, DB engine version, and AWS Region.

Contents

- [Using the Amazon RDS pricing page to determine DB instance class support in AWS Regions \(p. 17\)](#)
- [Using the AWS CLI to determine DB instance class support in AWS Regions \(p. 18\)](#)
 - [Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region \(p. 18\)](#)
 - [Listing the DB engine versions that support a specific DB instance class in an AWS Region \(p. 19\)](#)

Using the Amazon RDS pricing page to determine DB instance class support in AWS Regions

You can use the [Amazon RDS Pricing](#) page to determine the DB instance classes supported by each DB engine in a specific AWS Region.

To use the pricing page to determine the DB instance classes supported by each engine in a Region

1. Go to [Amazon RDS Pricing](#).
2. Choose a DB engine.
3. On the pricing page for the DB engine, choose **On-Demand DB Instances** or **Reserved DB Instances**.
4. To see the DB instance classes available in an AWS Region, choose the AWS Region in **Region**.

Other choices might be available for some DB engines, such as **Single-AZ Deployment** or **Multi-AZ Deployment**.

Using the AWS CLI to determine DB instance class support in AWS Regions

You can use the AWS CLI to determine which DB instance classes are supported for specific DB engines and DB engine versions in an AWS Region. The following table shows the valid DB engine values.

Engine names	Engine values in CLI commands	More information about versions
MariaDB	mariadb	MariaDB on Amazon RDS versions (p. 576)
Microsoft SQL Server	sqlserver-ee sqlserver-se sqlserver-ex sqlserver-web	Microsoft SQL Server versions on Amazon RDS (p. 637)
MySQL	mysql	MySQL on Amazon RDS versions (p. 828)
Oracle	oracle-ee oracle-se2 oracle-se	Oracle database engine release notes (p. 1245)
PostgreSQL	postgres	Supported PostgreSQL database versions (p. 1461)

For information about AWS Region names, see [AWS Regions \(p. 49\)](#).

The following examples demonstrate how to determine DB instance class support in an AWS Region using the `describe-orderable-db-instance-options` AWS CLI command.

Note

To limit the output, these examples show results only for the General Purpose SSD (gp2) storage type. If necessary, you can change the storage type to Provisioned IOPS (io1) or magnetic (standard) in the commands.

Topics

- [Listing the DB engine versions that support a specific DB instance class in an AWS Region \(p. 19\)](#)

Listing the DB instance classes that are supported by a specific DB engine version in an AWS Region

To list the DB instance classes that are supported by a specific DB engine version in an AWS Region, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine engine --engine-version version \
--query "*[ ].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}|[? \
StorageType=='gp2']|[ ].{DBInstanceClass:DBInstanceClass}" \
--output text \
```

```
--region region
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine engine --engine-version version ^
--query "[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}|[?
StorageType=='gp2'||[].{DBInstanceClass:DBInstanceClass}" ^
--output text ^
--region region
```

For example, the following command lists the supported DB instance classes for version 12.4 of the RDS for PostgreSQL DB engine in US East (N. Virginia).

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine postgres --engine-version 12.4 \ 
--query "[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}|[?
StorageType=='gp2'||[].{DBInstanceClass:DBInstanceClass}" \
--output text \
--region us-east-1
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine postgres --engine-version 12.4 ^
--query "[].{DBInstanceClass:DBInstanceClass,StorageType:StorageType}|[?
StorageType=='gp2'||[].{DBInstanceClass:DBInstanceClass}" ^
--output text ^
--region us-east-1
```

Listing the DB engine versions that support a specific DB instance class in an AWS Region

To list the DB engine versions that support a specific DB instance class in an AWS Region, run the following command.

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine engine --db-instance-
class DB_instance_class \
--query "[].{EngineVersion:EngineVersion,StorageType:StorageType}|[?
StorageType=='gp2'||[].{EngineVersion:EngineVersion}" \
--output text \
--region region
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine engine --db-instance-
class DB_instance_class ^
--query "[].{EngineVersion:EngineVersion,StorageType:StorageType}|[?
StorageType=='gp2'||[].{EngineVersion:EngineVersion}" ^
--output text ^
--region region
```

For example, the following command lists the DB engine versions of the RDS for PostgreSQL DB engine that support the db.r5.large DB instance class in US East (N. Virginia).

For Linux, macOS, or Unix:

```
aws rds describe-orderable-db-instance-options --engine postgres --db-instance-class db.r5.large \
    --query "[].{EngineVersion:EngineVersion,StorageType:StorageType}|[? StorageType=='gp2'||[].{EngineVersion:EngineVersion}]" \
    --output text \
    --region us-east-1
```

For Windows:

```
aws rds describe-orderable-db-instance-options --engine postgres --db-instance-class db.r5.large ^
    --query "[].{EngineVersion:EngineVersion,StorageType:StorageType}|[? StorageType=='gp2'||[].{EngineVersion:EngineVersion}]" ^
    --output text ^
    --region us-east-1
```

Changing your DB instance class

You can change the CPU and memory available to a DB instance by changing its DB instance class. To change the DB instance class, modify your DB instance by following the instructions in [Modifying an Amazon RDS DB instance \(p. 250\)](#).

Some instance classes require that your DB instance is in a VPC. If your current DB instance isn't in a VPC, and you want to use an instance class that requires one, first move your DB instance into a VPC. For more information, see [Moving a DB instance not in a VPC into a VPC \(p. 1735\)](#).

Configuring the processor for a DB instance class

Amazon RDS DB instance classes support Intel Hyper-Threading Technology, which enables multiple threads to run concurrently on a single Intel Xeon CPU core. Each thread is represented as a virtual CPU (vCPU) on the DB instance. A DB instance has a default number of CPU cores, which varies according to DB instance type. For example, a db.m4.xlarge DB instance type has two CPU cores and two threads per core by default—four vCPUs in total.

Note

Each vCPU is a hyperthread of an Intel Xeon CPU core.

Topics

- [Overview of configuring the processor \(p. 20\)](#)
- [CPU cores and threads per CPU core per DB instance class \(p. 21\)](#)
- [Setting the CPU cores and threads per CPU core for a DB instance class \(p. 25\)](#)

Overview of configuring the processor

In most cases, you can find a DB instance class that has a combination of memory and number of vCPUs to suit your workloads. However, you can also specify the following processor features to optimize your DB instance for specific workloads or business needs:

- **Number of CPU cores** – You can customize the number of CPU cores for the DB instance. You might do this to potentially optimize the licensing costs of your software with a DB instance that has sufficient amounts of RAM for memory-intensive workloads but fewer CPU cores.
- **Threads per core** – You can disable Intel Hyper-Threading Technology by specifying a single thread per CPU core. You might do this for certain workloads, such as high-performance computing (HPC) workloads.

You can control the number of CPU cores and threads for each core separately. You can set one or both in a request. After a setting is associated with a DB instance, the setting persists until you change it.

The processor settings for a DB instance are associated with snapshots of the DB instance. When a snapshot is restored, its restored DB instance uses the processor feature settings used when the snapshot was taken.

If you modify the DB instance class for a DB instance with nondefault processor settings, either specify default processor settings or explicitly specify processor settings at modification. This requirement ensures that you are aware of the third-party licensing costs that might be incurred when you modify the DB instance.

There is no additional or reduced charge for specifying processor features on an Amazon RDS DB instance. You're charged the same as for DB instances that are launched with default CPU configurations.

CPU cores and threads per CPU core per DB instance class

In the following table, you can find the DB instance classes that support setting a number of CPU cores and CPU threads per core. You can also find the default value and the valid values for the number of CPU cores and CPU threads per core for each DB instance class.

DB instance class	Default vCPUs	Default CPU cores	Default threads per core	Valid number of CPU cores	Valid number of threads per core
db.m5.large	2	1	2	1	1, 2

db.x1e.8xlarge	32	16	2	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16	1, 2

DB instance class	Default vCPUs	Default CPU cores	Default threads per core	Valid number of CPU cores	Valid number of threads per core
db.x1e.16xlarge	64	32	2	2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 26, 28, 30, 32	1, 2
db.x1e.32xlarge	128	64	2	4, 8, 12, 16, 20, 24, 28, 32, 36, 40, 44, 48, 52, 56, 60, 64	1, 2
db.z1d.large	2	1	2	1	1, 2
db.z1d.xlarge	4	2	2	2	1, 2
db.z1d.2xlarge	8	4	2	2, 4	1, 2
db.z1d.3xlarge	12	6	2	2, 4, 6	1, 2
db.z1d.6xlarge	24	12	2	2, 4, 6, 8, 10, 12	1, 2
db.z1d.12xlarge	48	24	2	4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24	1, 2

Currently, you can configure the number of CPU cores and threads per core only when the following conditions are met:

- You are configuring an Oracle DB instance. For information about the DB instance classes supported by different Oracle database editions, see [RDS for Oracle instance classes \(p. 992\)](#)
- Your instance is using the Bring Your Own License (BYOL) licensing option. For more information about Oracle licensing options, see [Oracle licensing options \(p. 990\)](#).

Note

You can use AWS CloudTrail to monitor and audit changes to the process configuration of Amazon RDS for Oracle DB instances. For more information about using CloudTrail, see [Working with AWS CloudTrail and Amazon RDS \(p. 557\)](#).

Setting the CPU cores and threads per CPU core for a DB instance class

You can configure the number of CPU cores and threads per core for the DB instance class when you perform the following operations:

- [Creating an Amazon RDS DB instance \(p. 141\)](#)
- [Modifying an Amazon RDS DB instance \(p. 250\)](#)
- [Restoring from a DB snapshot \(p. 349\)](#)
- [Restoring a DB instance to a specified time \(p. 389\)](#)

Note

When you modify a DB instance to configure the number of CPU cores or threads per core, there is a brief DB instance outage.

You can set the CPU cores and the threads per CPU core for a DB instance class using the AWS Management Console, the AWS CLI, or the RDS API.

Console

When you are creating, modifying, or restoring a DB instance, you set the DB instance class in the AWS Management Console. The **Instance specifications** section shows options for the processor. The following image shows the processor features options.

Instance specifications

Estimate your monthly costs for the DB Instance using the [AWS Simple Monthly Calculator](#)

DB engine
Oracle Database Enterprise Edition

License model [Info](#)
bring-your-own-license

DB engine version [Info](#)
Oracle 12.1.0.2.v12

DB instance class [Info](#)
db.r4.xlarge — 4 vCPU, 30.5 GiB RAM

Multi-AZ deployment [Info](#)
 Create replica in different zone
Creates a replica in a different Availability Zone (AZ) to provide data redundancy, eliminate I/O freezes, and minimize latency spikes during system backups.
 No

Storage type [Info](#)
Provisioned IOPS (SSD)

Allocated storage
100 GiB
(Minimum: 100 GiB, Maximum: 16384 GiB)

Provisioned IOPS [Info](#)
1000

▼ Additional configuration

Processor features

Override default values
You can change the number of CPU cores and threads per core on the DB instance class.

Core count [Info](#)
2

Threads per core [Info](#)
2

Set the following options to the appropriate values for your DB instance class under **Processor features**:

- **Core count** – Set the number of CPU cores using this option. The value must be equal to or less than the maximum number of CPU cores for the DB instance class.
- **Threads per core** – Specify **2** to enable multiple threads per core, or specify **1** to disable multiple threads per core.

When you modify or restore a DB instance, you can also set the CPU cores and the threads per CPU core to the defaults for the instance class.

When you view the details for a DB instance in the console, you can view the processor information for its DB instance class on the **Configuration** tab. The following image shows a DB instance class with one CPU core and multiple threads per core enabled.

Instance and IOPS	
Instance Class	db.r4.large
Core count	1
Threads per core	2
vCPU enabled	2
Storage Type	Provisioned IOPS (SSD)
IOPS	1000
Storage	100 GiB

For Oracle DB instances, the processor information only appears for Bring Your Own License (BYOL) DB instances.

AWS CLI

You can set the processor features for a DB instance when you run one of the following AWS CLI commands:

- [create-db-instance](#)

- [modify-db-instance](#)
- [restore-db-instance-from-db-snapshot](#)
- [restore-db-instance-from-s3](#)
- [restore-db-instance-to-point-in-time](#)

To configure the processor of a DB instance class for a DB instance by using the AWS CLI, include the `--processor-features` option in the command. Specify the number of CPU cores with the `coreCount` feature name, and specify whether multiple threads per core are enabled with the `threadsPerCore` feature name.

The option has the following syntax.

```
--processor-features "Name=coreCount,Value=<value>" "Name=threadsPerCore,Value=<value>"
```

The following are examples that configure the processor:

Examples

- [Setting the number of CPU cores for a DB instance \(p. 29\)](#)
- [Setting the number of CPU cores and disabling multiple threads for a DB instance \(p. 29\)](#)
- [Viewing the valid processor values for a DB instance class \(p. 30\)](#)
- [Returning to default processor settings for a DB instance \(p. 31\)](#)
- [Returning to the default number of CPU cores for a DB instance \(p. 31\)](#)
- [Returning to the default number of threads per core for a DB instance \(p. 32\)](#)

Setting the number of CPU cores for a DB instance

Example

The following example modifies `mydbinstance` by setting the number of CPU cores to 4. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--processor-features "Name=coreCount,Value=4" \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--processor-features "Name=coreCount,Value=4" ^
--apply-immediately
```

Setting the number of CPU cores and disabling multiple threads for a DB instance

Example

The following example modifies `mydbinstance` by setting the number of CPU cores to 4 and disabling multiple threads per core. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --processor-features "Name=coreCount,Value=4" "Name=threadsPerCore,Value=1" \  
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^  
  --processor-features "Name=coreCount,Value=4" "Name=threadsPerCore,Value=1" ^  
  --apply-immediately
```

Viewing the valid processor values for a DB instance class

Example

You can view the valid processor values for a particular DB instance class by running the [describe-orderable-db-instance-options](#) command and specifying the instance class for the --db-instance-class option. For example, the output for the following command shows the processor options for the db.r3.large instance class.

```
aws rds describe-orderable-db-instance-options --engine oracle-ee --db-instance-class db.r3.large
```

Following is sample output for the command in JSON format.

```
{  
    "SupportsIops": true,  
    "MaxIopsPerGib": 50.0,  
    "LicenseModel": "bring-your-own-license",  
    "DBInstanceClass": "db.r3.large",  
    "SupportsIAMDatabaseAuthentication": false,  
    "MinStorageSize": 100,  
    "AvailabilityZones": [  
        {  
            "Name": "us-west-2a"  
        },  
        {

        },  
        {  
            "Name": "threadsPerCore",  
            "DefaultValue": "2",  
            "AllowedValues": "1,2"  
        }  
    ]  
},
```

```
        "SupportsEnhancedMonitoring": true,  
        "SupportsPerformanceInsights": false,  
        "MinIopsPerDbInstance": 1000,  
        "StorageType": "io1",  
        "Vpc": false,  
        "SupportsStorageEncryption": true,  
        "Engine": "oracle-ee",  
        "MultiAZCapable": true  
    }
```

In addition, you can run the following commands for DB instance class processor information:

- [describe-db-instances](#) – Shows the processor information for the specified DB instance.
- [describe-db-snapshots](#) – Shows the processor information for the specified DB snapshot.
- [describe-valid-db-instance-modifications](#) – Shows the valid modifications to the processor for the specified DB instance.

In the output of the preceding commands, the values for the processor features are not null only if the following conditions are met:

- You are using an Oracle DB instance.
- Your Oracle DB instance supports changing processor values.
- The current CPU core and thread settings are set to nondefault values.

If the preceding conditions aren't met, you can get the instance type using [describe-db-instances](#). You can get the processor information for this instance type by running the EC2 operation [describe-instance-types](#).

Returning to default processor settings for a DB instance

Example

The following example modifies `mydbinstance` by returning its DB instance class to the default processor values for it. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \  
  --use-default-processor-features \  
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^  
  --use-default-processor-features ^  
  --apply-immediately
```

Returning to the default number of CPU cores for a DB instance

Example

The following example modifies `mydbinstance` by returning its DB instance class to the default number of CPU cores for it. The threads per core setting isn't changed. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--processor-features "Name=coreCount,Value=DEFAULT" \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--processor-features "Name=coreCount,Value=DEFAULT" ^
--apply-immediately
```

Returning to the default number of threads per core for a DB instance

Example

The following example modifies `mydbinstance` by returning its DB instance class to the default number of threads per core for it. The number of CPU cores setting isn't changed. The changes are applied immediately by using `--apply-immediately`. If you want to apply the changes during the next scheduled maintenance window, omit the `--apply-immediately` option.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--processor-features "Name=threadsPerCore,Value=DEFAULT" \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--processor-features "Name=threadsPerCore,Value=DEFAULT" ^
--apply-immediately
```

RDS API

You can set the processor features for a DB instance when you call one of the following Amazon RDS API operations:

- [CreateDBInstance](#)
- [ModifyDBInstance](#)
- [RestoreDBInstanceFromDBSnapshot](#)
- [RestoreDBInstanceFromS3](#)
- [RestoreDBInstanceToPointInTime](#)

To configure the processor features of a DB instance class for a DB instance by using the Amazon RDS API, include the `ProcessFeatures` parameter in the call.

The parameter has the following syntax.

```
ProcessFeatures "Name=coreCount,Value=<value>" "Name=threadsPerCore,Value=<value>"
```

Specify the number of CPU cores with the `coreCount` feature name, and specify whether multiple threads per core are enabled with the `threadsPerCore` feature name.

You can view the valid processor values for a particular instance class by running the [DescribeOrderableDBInstanceOptions](#) operation and specifying the instance class for the `DBInstanceClass` parameter. You can also use the following operations:

- [DescribeDBInstances](#) – Shows the processor information for the specified DB instance.
- [DescribeDBSnapshots](#) – Shows the processor information for the specified DB snapshot.
- [DescribeValidDBInstanceModifications](#) – Shows the valid modifications to the processor for the specified DB instance.

In the output of the preceding operations, the values for the processor features are not null only if the following conditions are met:

- You are using an Oracle DB instance.
- Your Oracle DB instance supports changing processor values.
- The current CPU core and thread settings are set to nondefault values.

If the preceding conditions aren't met, you can get the instance type using [DescribeDBInstances](#). You can get the processor information for this instance type by running the EC2 operation [DescribeInstanceTypes](#).

Hardware specifications for DB instance classes

The following terminology is used to describe hardware specifications for DB instance classes:

vCPU

The number of virtual central processing units (CPUs). A *virtual CPU* is a unit of capacity that you can use to compare DB instance classes. Instead of purchasing or leasing a particular processor to use for several months or years, you are renting capacity by the hour. Our goal is to make a consistent and specific amount of CPU capacity available, within the limits of the actual underlying hardware.

ECU

The relative measure of the integer processing power of an Amazon EC2 instance. To make it easy for developers to compare CPU capacity between different instance classes, we have defined an Amazon EC2 Compute Unit. The amount of CPU that is allocated to a particular instance is expressed in terms of these EC2 Compute Units. One ECU currently provides CPU capacity equivalent to a 1.0–1.2 GHz 2007 Opteron or 2007 Xeon processor.

Memory (GiB)

The RAM, in gibibytes, allocated to the DB instance. There is often a consistent ratio between memory and vCPU. As an example, take the db.r4 instance class, which has a memory to vCPU ratio similar to the db.r5 instance class. However, for most use cases the db.r5 instance class provides better, more consistent performance than the db.r4 instance class.

VPC Only

The instance class is supported only for DB instances that are in a VPC based on the Amazon VPC service. In some cases, you might want to use an instance class that requires a VPC but your current DB instance isn't in a VPC. In these cases, start by moving your DB instance into a VPC. For more information, see [Moving a DB instance not in a VPC into a VPC \(p. 1735\)](#).

EBS-Optimized

The DB instance uses an optimized configuration stack and provides additional, dedicated capacity for I/O. This optimization provides the best performance by minimizing contention between I/O and other traffic from your instance. For more information about Amazon EBS-optimized instances, see [Amazon EBS-Optimized instances](#) in the *Amazon EC2 User Guide for Linux Instances*.

Max. Bandwidth (Mbps)

The maximum bandwidth in megabits per second. Divide by 8 to get the expected throughput in megabytes per second.

Important

General Purpose SSD (gp2) volumes for Amazon RDS DB instances have a throughput limit of 250 MiB/s in most cases. However, the throughput limit can vary depending on volume size. For more information, see [Amazon EBS volume types](#) in the *Amazon EC2 User Guide for Linux Instances*. For information on estimating bandwidth for gp2 storage, see [General Purpose SSD storage \(p. 40\)](#).

Network Performance

The network speed relative to other DB instance classes.

In the following table, you can find hardware details about the Amazon RDS DB instance classes.

For information about Amazon RDS DB engine support for each DB instance class, see [Supported DB engines for DB instance classes \(p. 8\)](#).

Instance class	vCPU	ECU	Memory (GiB)	VPC only	EBS optimized	Max. bandwidth (mbps)	Network performance
db.m6g – Standard instance classes powered by AWS Graviton2 processors							
db.m6g.16xlarge	64	–	256	Yes	Yes	19,000	25 Gbps

db.t2.medium	2	Variable	4	Yes	No	—	Moderate
db.t2.small	1	Variable	2	Yes	No	—	Low
db.t2.micro	1	Variable	1	Yes	No	—	Low

* These DB instance classes can support maximum performance for 30 minutes at least once every 24 hours. For more information on baseline performance of these instance types, see [Amazon EBS-optimized instances](#) in the *Amazon EC2 User Guide for Linux Instances*.

** These DB instance classes can support maximum performance for 30 minutes at least once every 24 hours. For more information on baseline performance of these instance types, see [Amazon EBS-optimized instances](#) in the *Amazon EC2 User Guide for Linux Instances*.

*** The r3.8xlarge instance doesn't have dedicated EBS bandwidth and therefore doesn't offer EBS optimization. On this instance, network traffic and Amazon EBS traffic share the same 10-gigabit network interface.

Amazon RDS DB instance storage

DB instances for Amazon RDS for MySQL, MariaDB, PostgreSQL, Oracle, and Microsoft SQL Server use Amazon Elastic Block Store (Amazon EBS) volumes for database and log storage. Depending on the amount of storage requested, Amazon RDS automatically stripes across multiple Amazon EBS volumes to enhance performance.

Amazon RDS storage types

Amazon RDS provides three storage types: General Purpose SSD (also known as gp2), Provisioned IOPS SSD (also known as io1), and magnetic (also known as standard). They differ in performance characteristics and price, which means that you can tailor your storage performance and cost to the needs of your database workload. You can create MySQL, MariaDB, Oracle, and PostgreSQL RDS DB instances with up to 64 tebibytes (TiB) of storage. You can create SQL Server RDS DB instances with up to 16 TiB of storage. For this amount of storage, use the Provisioned IOPS SSD and General Purpose SSD storage types.

The following list briefly describes the three storage types:

- **General Purpose SSD** – General Purpose SSD volumes offer cost-effective storage that is ideal for a broad range of workloads. These volumes deliver single-digit millisecond latencies and the ability to burst to 3,000 IOPS for extended periods of time. Baseline performance for these volumes is determined by the volume's size.

For more information about General Purpose SSD storage, including the storage size ranges, see [General Purpose SSD storage \(p. 40\)](#).

- **Provisioned IOPS** – Provisioned IOPS storage is designed to meet the needs of I/O-intensive workloads, particularly database workloads, that require low I/O latency and consistent I/O throughput.

For more information about provisioned IOPS storage, including the storage size ranges, see [Provisioned IOPS SSD storage \(p. 42\)](#).

- **Magnetic** – Amazon RDS also supports magnetic storage for backward compatibility. We recommend that you use General Purpose SSD or Provisioned IOPS for any new storage needs. The maximum amount of storage allowed for DB instances on magnetic storage is less than that of the other storage types. For more information, see [Magnetic storage \(p. 44\)](#).

Several factors can affect the performance of Amazon EBS volumes, such as instance configuration, I/O characteristics, and workload demand. For more information about getting the most out of your Provisioned IOPS volumes, see [Amazon EBS volume performance](#).

General Purpose SSD storage

General Purpose SSD storage offers cost-effective storage that is acceptable for most database workloads. The following are the storage size ranges for General Purpose SSD DB instances:

- MariaDB, MySQL, Oracle, and PostgreSQL database instances: 20 GiB–64 TiB
- SQL Server for Enterprise, Standard, Web, and Express editions: 20 GiB–16 TiB

Baseline I/O performance for General Purpose SSD storage is 3 IOPS for each GiB, with a minimum of 100 IOPS. This relationship means that larger volumes have better performance. For example, baseline performance for a 100-GiB volume is 300 IOPS. Baseline performance for a 1-TiB volume is 3,000 IOPS. And baseline performance for a 5.34-TiB volume is 16,000 IOPS.

Volumes below 1 TiB in size also have ability to burst to 3,000 IOPS for extended periods of time. Burst is not relevant for volumes above 1 TiB. Instance I/O credit balance determines burst performance. For more information about instance I/O credits, see [I/O credits and burst performance \(p. 41\)](#).

Many workloads never deplete the burst balance, making General Purpose SSD an ideal storage choice for many workloads. However, some workloads can exhaust the 3,000 IOPS burst storage credit balance, so you should plan your storage capacity to meet the needs of your workloads.

Note

DB instances that use General Purpose SSD storage can experience much longer latency after read replica creation, Multi-AZ conversion, and DB snapshot restoration than instances that use Provisioned IOPS storage. If you need a DB instance with minimum latency after these operations, we recommend using Provisioned IOPS storage.

I/O credits and burst performance

General Purpose SSD storage performance is governed by volume size, which dictates the base performance level of the volume and how quickly it accumulates I/O credits. Larger volumes have higher base performance levels and accumulate I/O credits faster. *I/O credits* represent the available bandwidth that your General Purpose SSD storage can use to burst large amounts of I/O when more than the base level of performance is needed. The more I/O credits your storage has for I/O, the more time it can burst beyond its base performance level and the better it performs when your workload requires more performance.

When using General Purpose SSD storage, your DB instance receives an initial I/O credit balance of 5.4 million I/O credits. This initial credit balance is enough to sustain a burst performance of 3,000 IOPS for 30 minutes. This balance is designed to provide a fast initial boot cycle for boot volumes and to provide a good bootstrapping experience for other applications. Volumes earn I/O credits at the baseline performance rate of 3 IOPS for each GiB of volume size. For example, a 100-GiB SSD volume has a baseline performance of 300 IOPS.

When your storage requires more than the base performance I/O level, it uses I/O credits in the I/O credit balance to burst to the required performance level. Such a burst goes to a maximum of 3,000 IOPS. Storage larger than 1,000 GiB has a base performance that is equal or greater than the maximum burst performance. When your storage uses fewer I/O credits than it earns in a second, unused I/O credits are added to the I/O credit balance. The maximum I/O credit balance for a DB instance using General Purpose SSD storage is equal to the initial I/O credit balance (5.4 million I/O credits).

Suppose that your storage uses all of its I/O credit balance. If so, its maximum performance remains at the base performance level until I/O demand drops below the base level and unused I/O credits are added to the I/O credit balance. (The *base performance level* is the rate at which your storage earns I/O credits.) The more storage, the greater the base performance is and the faster it replenishes the I/O credit balance.

Note

Storage conversions between magnetic storage and General Purpose SSD storage can potentially deplete your I/O credit balance, resulting in longer conversion times. For more information about scaling storage, see [Working with storage for Amazon RDS DB instances \(p. 316\)](#).

The following table lists several storage sizes. For each storage size, it lists the associated base performance of the storage, which is also the rate at which it accumulates I/O credits. The table also lists the burst duration at the 3,000 IOPS maximum, when starting with a full I/O credit balance. In addition, the table lists the time in seconds that the storage takes to refill an empty I/O credit balance.

Note

The IOPS figure reaches its maximum value at a volume storage size of 5,334 GiB.

Storage size (GiB)	Base performance (IOPS)	Maximum burst duration at 3,000 IOPS (seconds)	Seconds to fill empty I/O credit balance
1	100	1,862	54,000
100	300	2,000	18,000
250	750	2,400	7,200
500	1,500	3,600	3,600
750	2,250	7,200	2,400
1,000	3,000	Infinite	N/A
5,334	16,000	N/A	N/A

The burst duration of your storage depends on the size of the storage, the burst IOPS required, and the I/O credit balance when the burst begins. This relationship is shown in the equation following.

$$\text{Burst duration} = \frac{(\text{Credit balance})}{(\text{Burst IOPS}) - 3 * (\text{Storage size in GiB})}$$

You might notice that your storage performance is frequently limited to the base level due to an empty I/O credit balance. If so, consider allocating more General Purpose SSD storage with a higher base performance level. Alternatively, you can switch to Provisioned IOPS storage for workloads that require sustained IOPS performance.

For workloads with steady state I/O requirements, provisioning less than 100 GiB of General Purpose SSD storage might result in higher latencies if you exhaust your I/O credit balance.

Note

In general, most workloads never exceed the I/O credit balance.

For a more detailed description of how baseline performance and I/O credit balance affect performance see [Understanding burst vs. baseline performance with Amazon RDS and GP2](#).

Provisioned IOPS SSD storage

For a production application that requires fast and consistent I/O performance, we recommend Provisioned IOPS (input/output operations per second) storage. Provisioned IOPS storage is a storage type that delivers predictable performance, and consistently low latency. Provisioned IOPS storage is optimized for online transaction processing (OLTP) workloads that have consistent performance requirements. Provisioned IOPS helps performance tuning of these workloads.

Note

Your database workload might not be able to achieve 100 percent of the IOPS that you have provisioned. For more information, see [Factors that affect storage performance \(p. 45\)](#).

When you create a DB instance, you specify the IOPS rate and the size of the volume. The ratio of IOPS to allocated storage (in GiB) must be at least 0.5. Amazon RDS provides that IOPS rate for the DB instance until you change it.

The following table shows the range of Provisioned IOPS and storage size range for each database engine.

Database engine	Range of Provisioned IOPS	Range of storage
MariaDB	1,000–80,000 IOPS	100 GiB–64 TiB
SQL Server Enterprise, Standard, and Web Editions	1,000–64,000 IOPS	20 GiB–16 TiB
SQL Server Express Edition	1,000–64,000 IOPS	100 GiB–16 TiB
MySQL	1,000–80,000 IOPS	100 GiB–64 TiB
Oracle	1,000–256,000 IOPS	100 GiB–64 TiB
PostgreSQL	1,000–80,000 IOPS	100 GiB–64 TiB

Note

For SQL Server, the maximum IOPS of 64,000 is guaranteed only on [Nitro-based instances](#) that are on the m5, m5d, r5, r5b, r5d, and z1d instance types. Other instance families guarantee performance up to 32,000 IOPS.

For Oracle, the maximum IOPS of 256,000 is guaranteed only on [Nitro-based instances](#) that are on the r5b instance type. Other instance families guarantee performance up to 80,000 IOPS.

For PostgreSQL, the maximum IOPS on the db.m5.8xlarge, db.m5.16xlarge, db.r5.8xlarge, and db.r5.16xlarge instance classes is 40,000.

Important

Depending on the instance class you're using, you might see lower IOPS performance than the maximum that RDS allows you to provision. For specific information on IOPS performance for DB instance classes, see [Amazon EBS-optimized instances](#). We recommend that you determine the maximum IOPS for the instance class before setting a Provisioned IOPS value for your DB instance.

Combining Provisioned IOPS storage with Multi-AZ deployments or read replicas

For production OLTP use cases, we recommend that you use Multi-AZ deployments for enhanced fault tolerance with Provisioned IOPS storage for fast and predictable performance.

You can also use Provisioned IOPS SSD storage with read replicas for MySQL, MariaDB or PostgreSQL. The type of storage for a read replica is independent of that on the primary DB instance. For example, you might use General Purpose SSD for read replicas with a primary DB instance that uses Provisioned IOPS SSD storage to reduce costs. However, your read replica's performance in this case might differ from that of a configuration where both the primary DB instance and the read replicas use Provisioned IOPS SSD storage.

Provisioned IOPS storage costs

With Provisioned IOPS storage, you are charged for the provisioned resources whether or not you use them in a given month.

For more information about pricing, see [Amazon RDS pricing](#).

Getting the best performance from Amazon RDS Provisioned IOPS SSD storage

If your workload is I/O constrained, using Provisioned IOPS SSD storage can increase the number of I/O requests that the system can process concurrently. Increased concurrency allows for decreased latency

because I/O requests spend less time in a queue. Decreased latency allows for faster database commits, which improves response time and allows for higher database throughput.

Provisioned IOPS SSD storage provides a way to reserve I/O capacity by specifying IOPS. However, as with any other system capacity attribute, its maximum throughput under load is constrained by the resource that is consumed first. That resource might be network bandwidth, CPU, memory, or database internal resources.

Magnetic storage

Amazon RDS also supports magnetic storage for backward compatibility. We recommend that you use General Purpose SSD or Provisioned IOPS SSD for any new storage needs. The following are some limitations for magnetic storage:

- Doesn't allow you to scale storage when using the SQL Server database engine.
- Doesn't support storage autoscaling.
- Doesn't support elastic volumes.
- Limited to a maximum size of 3 TiB.
- Limited to a maximum of 1,000 IOPS.

Monitoring storage performance

Amazon RDS provides several metrics that you can use to determine how your DB instance is performing. You can view the metrics on the summary page for your instance in Amazon RDS Management Console. You can also use Amazon CloudWatch to monitor these metrics. For more information, see [Viewing DB instance metrics \(p. 548\)](#). Enhanced Monitoring provides more detailed I/O metrics; for more information, see [Using Enhanced Monitoring \(p. 471\)](#).

The following metrics are useful for monitoring storage for your DB instance:

- **IOPS** – The number of I/O operations completed each second. This metric is reported as the average IOPS for a given time interval. Amazon RDS reports read and write IOPS separately on 1-minute intervals. Total IOPS is the sum of the read and write IOPS. Typical values for IOPS range from zero to tens of thousands per second.
- **Latency** – The elapsed time between the submission of an I/O request and its completion. This metric is reported as the average latency for a given time interval. Amazon RDS reports read and write latency separately on 1-minute intervals in units of seconds. Typical values for latency are in the millisecond (ms). For example, Amazon RDS reports 2 ms as 0.002 seconds.
- **Throughput** – The number of bytes each second that are transferred to or from disk. This metric is reported as the average throughput for a given time interval. Amazon RDS reports read and write throughput separately on 1-minute intervals using units of megabytes per second (MB/s). Typical values for throughput range from zero to the I/O channel's maximum bandwidth.
- **Queue Depth** – The number of I/O requests in the queue waiting to be serviced. These are I/O requests that have been submitted by the application but have not been sent to the device because the device is busy servicing other I/O requests. Time spent waiting in the queue is a component of latency and service time (not available as a metric). This metric is reported as the average queue depth for a given time interval. Amazon RDS reports queue depth in 1-minute intervals. Typical values for queue depth range from zero to several hundred.

Measured IOPS values are independent of the size of the individual I/O operation. This means that when you measure I/O performance, you should look at the throughput of the instance, not simply the number of I/O operations.

Factors that affect storage performance

Both system activities and database workload can affect storage performance.

System activities

The following system-related activities consume I/O capacity and might reduce database instance performance while in progress:

- Multi-AZ standby creation
- Read replica creation
- Changing storage types

Database workload

In some cases your database or application design results in concurrency issues, locking, or other forms of database contention. In these cases, you might not be able to use all the provisioned bandwidth directly. In addition, you may encounter the following workload-related situations:

- The throughput limit of the underlying instance type is reached.
- Queue depth is consistently less than 1 because your application is not driving enough I/O operations.
- You experience query contention in the database even though some I/O capacity is unused.

If there isn't at least one system resource that is at or near a limit, and adding threads doesn't increase the database transaction rate, the bottleneck is most likely contention in the database. The most common forms are row lock and index page lock contention, but there are many other possibilities. If this is your situation, you should seek the advice of a database performance tuning expert.

DB instance class

To get the most performance out of your Amazon RDS database instance, choose a current generation instance type with enough bandwidth to support your storage type. For example, you can choose EBS-optimized instances and instances with 10-gigabit network connectivity.

Important

Depending on the instance class you're using, you might see lower IOPS performance than the maximum that RDS allows you to provision. For specific information on IOPS performance for DB instance classes, see [Amazon EBS-optimized instances](#). We recommend that you determine the maximum IOPS for the instance class before setting a Provisioned IOPS value for your DB instance.

We encourage you to use the latest generation of instances to get the best performance. Previous generation DB instances have a lower instance storage limit. The following table shows the maximum storage that each DB instance class can scale to for each database engine. All values are in tebibytes (TiB).

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
db.m5 – Latest Generation Standard Instance Classes					
db.m5.24xlarge	64	16	64	64	64
db.m5.16xlarge	64	16	64	64	64
db.m5.12xlarge	64	16	64	64	64

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL

db.x1e.32xlarge		16		64	
db.x1e.16xlarge		16		64	
db.x1e.8xlarge		16		64	
db.x1e.4xlarge		16		64	
db.x1e.2xlarge		16		64	
db.x1e.xlarge		16		64	

Instance class	MariaDB	Microsoft SQL Server	MySQL	Oracle	PostgreSQL
db.x1 – Current Generation Memory Optimized Instance Classes					
db.x1.32xlarge		16		64	
db.x1.16xlarge		16		64	

For Oracle, scaling up to 80,000 IOPS is only supported on the following instance classes.

- db.m5.24xlarge
- db.r5.24xlarge
- db.x1.32xlarge
- db.x1e.32xlarge

For more details on all instance classes supported, see [Previous generation DB instances](#).

Regions, Availability Zones, and Local Zones

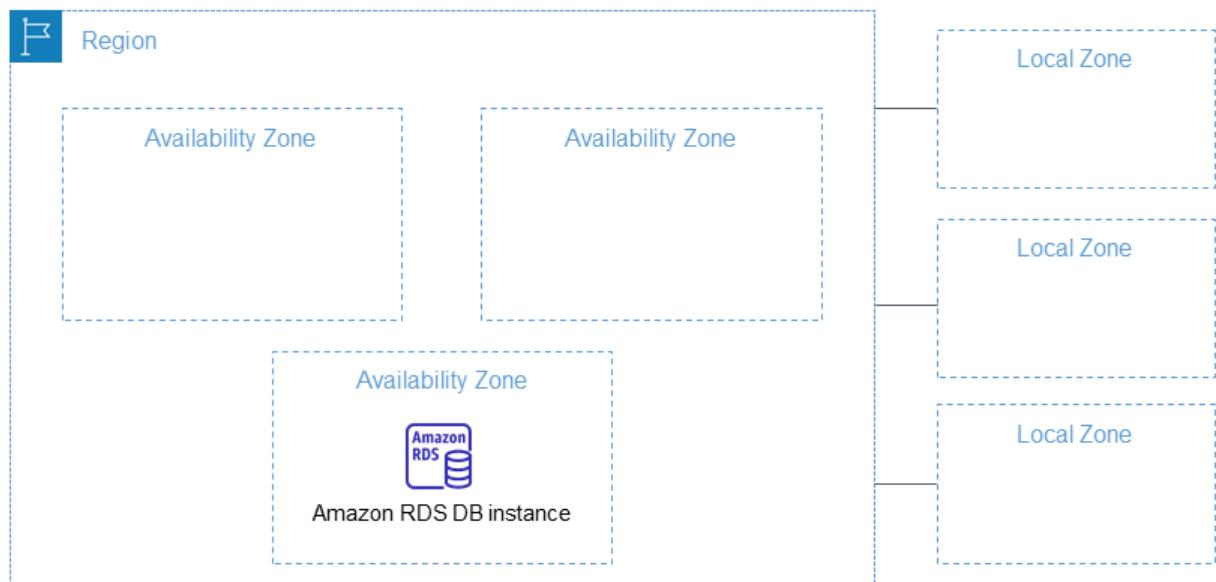

Amazon cloud computing resources are hosted in multiple locations world-wide. These locations are composed of AWS Regions, Availability Zones, and Local Zones. Each *AWS Region* is a separate geographic area. Each AWS Region has multiple, isolated locations known as *Availability Zones*.

Note

For information about finding the Availability Zones for an AWS Region, see [Describing your Regions, Availability Zones, and Local Zones](#) in the Amazon EC2 documentation.

By using Local Zones, you can place resources, such as compute and storage, in multiple locations closer to your users. Amazon RDS enables you to place resources, such as DB instances, and data in multiple locations. Resources aren't replicated across AWS Regions unless you do so specifically.

Amazon operates state-of-the-art, highly-available data centers. Although rare, failures can occur that affect the availability of instances that are in the same location. If you host all your instances in a single location that is affected by such a failure, none of your instances is available.

It is important to remember that each AWS Region is completely independent. Any Amazon RDS activity you initiate (for example, creating database instances or listing available database instances) runs only in your current default AWS Region. The default AWS Region can be changed in the console, by setting the `AWS_DEFAULT_REGION` environment variable, or it can be overridden by using the `--region` parameter with the AWS Command Line Interface (AWS CLI). For more information, see [Configuring the AWS Command Line Interface](#), specifically the sections about environment variables and command line options.

Amazon RDS supports special AWS Regions called AWS GovCloud (US) that are designed to allow US government agencies and customers to move more sensitive workloads into the cloud. The AWS GovCloud (US) Regions address the US government's specific regulatory and compliance requirements. For more information, see [What is AWS GovCloud \(US\)?](#)

To create or work with an Amazon RDS DB instance in a specific AWS Region, use the corresponding regional service endpoint.

AWS Regions

Each AWS Region is designed to be isolated from the other AWS Regions. This design achieves the greatest possible fault tolerance and stability.

When you view your resources, you see only the resources that are tied to the AWS Region that you specified. This is because AWS Regions are isolated from each other, and we don't automatically replicate resources across AWS Regions.

Region availability

The following table shows the AWS Regions where Amazon RDS is currently available and the endpoint for each Region.

Region Name	Region	Endpoint	Protocol	
US East (Ohio)	us-east-2	rds.us-east-2.amazonaws.com rds-fips.us-east-2.amazonaws.com	HTTPS HTTPS	
US East (N. Virginia)	us-east-1	rds.us-east-1.amazonaws.com rds-fips.us-east-1.amazonaws.com	HTTPS HTTPS	
US West (N. California)	us-west-1	rds.us-west-1.amazonaws.com rds-fips.us-west-1.amazonaws.com	HTTPS HTTPS	
US West (Oregon)	us-west-2	rds.us-west-2.amazonaws.com rds-fips.us-west-2.amazonaws.com	HTTPS HTTPS	
Africa (Cape Town)	af-south-1	rds.af-south-1.amazonaws.com	HTTPS	
Asia Pacific (Hong Kong)	ap-east-1	rds.ap-east-1.amazonaws.com	HTTPS	
Asia Pacific (Mumbai)	ap-south-1	rds.ap-south-1.amazonaws.com	HTTPS	
Asia Pacific (Osaka)	ap-northeast-3	rds.ap-northeast-3.amazonaws.com	HTTPS	
Asia Pacific (Seoul)	ap-northeast-2	rds.ap-northeast-2.amazonaws.com	HTTPS	
Asia Pacific (Singapore)	ap-southeast-1	rds.ap-southeast-1.amazonaws.com	HTTPS	
Asia Pacific (Sydney)	ap-southeast-2	rds.ap-southeast-2.amazonaws.com	HTTPS	

Region Name	Region	Endpoint	Protocol	
Asia Pacific (Tokyo)	ap-northeast-1	rds.ap-northeast-1.amazonaws.com	HTTPS	
Canada (Central)	ca-central-1	rds.ca-central-1.amazonaws.com	HTTPS	
		rds-fips.ca-central-1.amazonaws.com	HTTPS	
China (Beijing)	cn-north-1	rds.cn-north-1.amazonaws.com.cn	HTTPS	
China (Ningxia)	cn-northwest-1	rds.cn-northwest-1.amazonaws.com.cn	HTTPS	
Europe (Frankfurt)	eu-central-1	rds.eu-central-1.amazonaws.com	HTTPS	
Europe (Ireland)	eu-west-1	rds.eu-west-1.amazonaws.com	HTTPS	
Europe (London)	eu-west-2	rds.eu-west-2.amazonaws.com	HTTPS	
Europe (Milan)	eu-south-1	rds.eu-south-1.amazonaws.com	HTTPS	
Europe (Paris)	eu-west-3	rds.eu-west-3.amazonaws.com	HTTPS	
Europe (Stockholm)	eu-north-1	rds.eu-north-1.amazonaws.com	HTTPS	
Middle East (Bahrain)	me-south-1	rds.me-south-1.amazonaws.com	HTTPS	
South America (São Paulo)	sa-east-1	rds.sa-east-1.amazonaws.com	HTTPS	
AWS GovCloud (US-East)	us-gov-east-1	rds.us-gov-east-1.amazonaws.com	HTTPS	
AWS GovCloud (US-West)	us-gov-west-1	rds.us-gov-west-1.amazonaws.com	HTTPS	

If you do not explicitly specify an endpoint, the US West (Oregon) endpoint is the default.

When you work with a DB instance using the AWS CLI or API operations, make sure that you specify its regional endpoint.

Availability Zones

When you create a DB instance, you can choose an Availability Zone or have Amazon RDS choose one for you randomly. An Availability Zone is represented by an AWS Region code followed by a letter identifier (for example, us-east-1a).

You can't choose the Availability Zones for the primary and secondary DB instances in a Multi-AZ DB deployment. Amazon RDS chooses them for you randomly. For more information about Multi-AZ deployments, see [High availability \(Multi-AZ\) for Amazon RDS \(p. 53\)](#).

Note

Random selection of Availability Zones by RDS doesn't guarantee an even distribution of DB instances among Availability Zones within a single account or DB subnet group. You can request a specific AZ when you create or modify a Single-AZ instance, and you can use more-specific DB subnet groups for Multi-AZ instances. For more information, see [Creating an Amazon RDS DB instance \(p. 141\)](#) and [Modifying an Amazon RDS DB instance \(p. 250\)](#).

Local Zones

A *Local Zone* is an extension of an AWS Region that is geographically close to your users. You can extend any VPC from the parent AWS Region into Local Zones by creating a new subnet and assigning it to the AWS Local Zone. When you create a subnet in a Local Zone, your VPC is extended to that Local Zone. The subnet in the Local Zone operates the same as other subnets in your VPC.

When you create a DB instance, you can choose a subnet in a Local Zone. Local Zones have their own connections to the internet and support AWS Direct Connect. Thus, resources created in a Local Zone can serve local users with very low-latency communications. For more information, see [AWS Local Zones](#).

A Local Zone is represented by an AWS Region code followed by an identifier that indicates the location, for example us-west-2-lax-1a.

Note

A Local Zone can't be included in a Multi-AZ deployment.

To use a Local Zone

1. Enable the Local Zone in the Amazon EC2 console.

For more information, see [Enabling Local Zones in the Amazon EC2 User Guide for Linux Instances](#).

2. Create a subnet in the Local Zone.

For more information, see [Creating a subnet in your VPC](#) in the *Amazon VPC User Guide*.

3. Create a DB subnet group in the Local Zone.

When you create a DB subnet group, choose the Availability Zone group for the Local Zone.

For more information, see [Creating a DB instance in a VPC \(p. 1730\)](#).

4. Create a DB instance that uses the DB subnet group in the Local Zone.

For more information, see [Creating an Amazon RDS DB instance \(p. 141\)](#).

Important

Currently, Local Zones are only available in the US West (Oregon) Region. In this AWS Region, the Los Angeles AWS Local Zone is available.

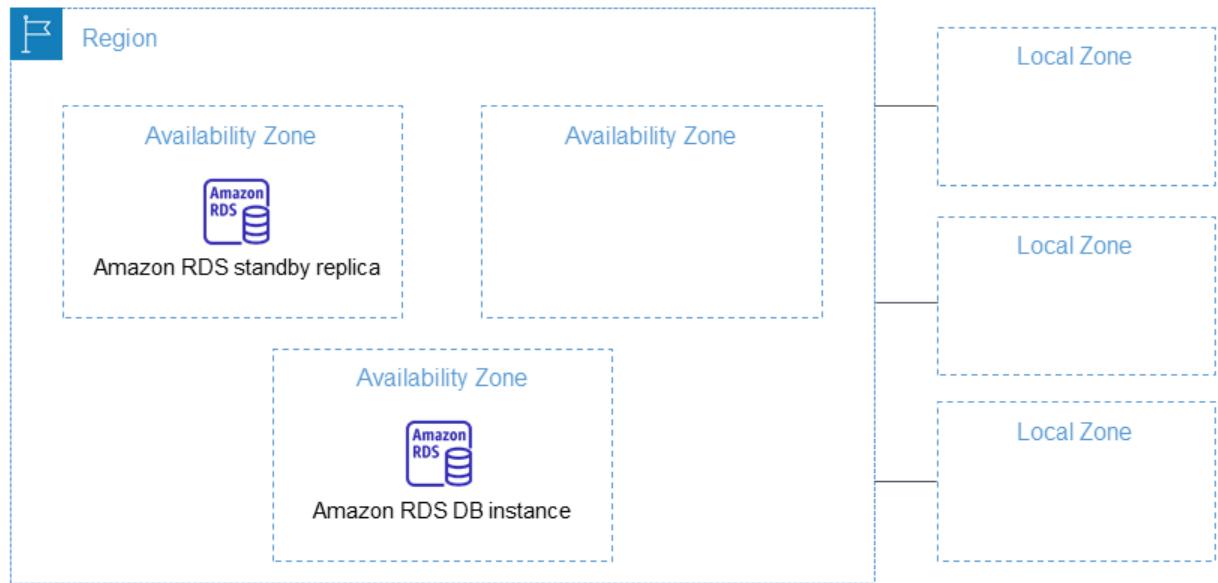

High availability (Multi-AZ) for Amazon RDS

Amazon RDS provides high availability and failover support for DB instances using Multi-AZ deployments. Amazon RDS uses several different technologies to provide failover support. Multi-AZ deployments for MariaDB, MySQL, Oracle, and PostgreSQL DB instances use Amazon's failover technology. SQL Server DB instances use SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). For information on SQL Server version support for Multi-AZ, see [Multi-AZ deployments for Microsoft SQL Server \(p. 698\)](#).

In a Multi-AZ deployment, Amazon RDS automatically provisions and maintains a synchronous standby replica in a different Availability Zone. The primary DB instance is synchronously replicated across Availability Zones to a standby replica to provide data redundancy, eliminate I/O freezes, and minimize latency spikes during system backups. Running a DB instance with high availability can enhance availability during planned system maintenance, and help protect your databases against DB instance failure and Availability Zone disruption. For more information on Availability Zones, see [Regions, Availability Zones, and Local Zones \(p. 49\)](#).

Note

The high-availability feature isn't a scaling solution for read-only scenarios; you can't use a standby replica to serve read traffic. To serve read-only traffic, you use a read replica instead. For more information, see [Working with read replicas \(p. 278\)](#).

Using the RDS console, you can create a Multi-AZ deployment by simply specifying Multi-AZ when creating a DB instance. You can use the console to convert existing DB instances to Multi-AZ deployments by modifying the DB instance and specifying the Multi-AZ option. You can also specify a Multi-AZ deployment with the AWS CLI or Amazon RDS API. Use the [create-db-instance](#) or [modify-db-instance](#) CLI command, or the [CreateDBInstance](#) or [ModifyDBInstance](#) API operation.

The RDS console shows the Availability Zone of the standby replica (called the secondary AZ). You can also use the [describe-db-instances](#) CLI command or the [DescribeDBInstances](#) API operation to find the secondary AZ.

DB instances using Multi-AZ deployments can have increased write and commit latency compared to a Single-AZ deployment, due to the synchronous data replication that occurs. You might have a change in latency if your deployment fails over to the standby replica, although AWS is engineered with low-latency network connectivity between Availability Zones. For production workloads, we recommend

that you use Provisioned IOPS and DB instance classes that are optimized for Provisioned IOPS for fast, consistent performance. For more information about DB instance classes, see [DB instance classes \(p. 7\)](#).

Modifying a DB instance to be a Multi-AZ deployment

If you have a DB instance in a Single-AZ deployment and modify it to a Multi-AZ deployment (for engines other than Amazon Aurora), Amazon RDS takes several steps. First, Amazon RDS takes a snapshot of the primary DB instance from your deployment and then restores the snapshot into another Availability Zone. Amazon RDS then sets up synchronous replication between your primary DB instance and the new instance.

For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

Important

This action avoids downtime when you convert from Single-AZ to Multi-AZ, but you can experience a performance impact during and after converting to Multi-AZ. This impact can be significant for large write-intensive DB instances.

To enable Multi-AZ for a DB instance, RDS takes a snapshot of the primary DB instance's EBS volume and restores it on the newly created standby replica, and then synchronizes both volumes. New volumes created from existing EBS snapshots load lazily in the background. This capability permits large volumes to be restored from a snapshot quickly, but there is the possibility of added latency during and after the modification is complete. For more information, see [Restoring an Amazon EBS volume from a snapshot](#) in the Amazon EC2 documentation.

After the modification is complete, Amazon RDS triggers an event (RDS-EVENT-0025) that indicates the process is complete. You can monitor Amazon RDS events; for more information about events, see [Using Amazon RDS event notification \(p. 487\)](#).

Failover process for Amazon RDS

In the event of a planned or unplanned outage of your DB instance, Amazon RDS automatically switches to a standby replica in another Availability Zone if you have enabled Multi-AZ. The time it takes for the failover to complete depends on the database activity and other conditions at the time the primary DB instance became unavailable. Failover times are typically 60–120 seconds. However, large transactions or a lengthy recovery process can increase failover time. When the failover is complete, it can take additional time for the RDS console to reflect the new Availability Zone.

Note

You can force a failover manually when you reboot a DB instance. For more information, see [Rebooting a DB instance \(p. 276\)](#).

Amazon RDS handles failovers automatically so you can resume database operations as quickly as possible without administrative intervention. The primary DB instance switches over automatically to the standby replica if any of the conditions described in the following table occurs. You can view these failover reasons in the event log.

Failover reason	Description
The operating system underlying the RDS database instance is being patched in an offline operation.	A failover was triggered during the maintenance window for an OS patch or a security update. For more information, see Maintaining a DB instance (p. 264) .
The primary host of the RDS Multi-AZ instance is unhealthy.	The Multi-AZ deployment detected an impaired primary DB instance and failed over.

Failover reason	Description
The primary host of the RDS Multi-AZ instance is unreachable due to loss of network connectivity.	RDS monitoring detected a network reachability failure to the primary DB instance and triggered a failover.
The RDS instance was modified by customer.	<p>An RDS DB instance modification triggered a failover.</p> <p>For more information, see Modifying an Amazon RDS DB instance (p. 250).</p>
The RDS Multi-AZ primary instance is busy and unresponsive.	<p>The primary DB instance is unresponsive. We recommend that you do the following:</p> <ul style="list-style-type: none"> Examine the event and CloudWatch logs for excessive CPU, memory, or swap space usage. For more information, see Using Amazon RDS event notification (p. 487) and Getting CloudWatch Events and Amazon EventBridge events for Amazon RDS (p. 551). Evaluate your workload to determine whether you're using the appropriate DB instance class. For more information, see DB instance classes (p. 7). Use Enhanced Monitoring for real-time operating system metrics. For more information, see Using Enhanced Monitoring (p. 471). Use Performance Insights to help analyze any issues that affect your DB instance's performance. For more information, see Using Performance Insights on Amazon RDS (p. 412). <p>For more information on these recommendations, see Overview of monitoring Amazon RDS (p. 400) and Best practices for Amazon RDS (p. 128).</p>
The storage volume underlying the primary host of the RDS Multi-AZ instance experienced a failure.	The Multi-AZ deployment detected a storage issue on the primary DB instance and failed over.
The user requested a failover of the DB instance.	<p>You rebooted the DB instance and chose Reboot with failover.</p> <p>For more information, see Rebooting a DB instance (p. 276).</p>

There are several ways to determine if your Multi-AZ DB instance has failed over:

- DB event subscriptions can be set up to notify you by email or SMS that a failover has been initiated. For more information about events, see [Using Amazon RDS event notification \(p. 487\)](#).
- You can view your DB events by using the Amazon RDS console or API operations.

- You can view the current state of your Multi-AZ deployment by using the Amazon RDS console and API operations.

For information on how you can respond to failovers, reduce recovery time, and other best practices for Amazon RDS, see [Best practices for Amazon RDS \(p. 128\)](#).

Setting the JVM TTL for DNS name lookups

The failover mechanism automatically changes the Domain Name System (DNS) record of the DB instance to point to the standby DB instance. As a result, you need to re-establish any existing connections to your DB instance. In a Java virtual machine (JVM) environment, due to how the Java DNS caching mechanism works, you might need to reconfigure JVM settings.

The JVM caches DNS name lookups. When the JVM resolves a hostname to an IP address, it caches the IP address for a specified period of time, known as the *time-to-live* (TTL).

Because AWS resources use DNS name entries that occasionally change, we recommend that you configure your JVM with a TTL value of no more than 60 seconds. Doing this makes sure that when a resource's IP address changes, your application can receive and use the resource's new IP address by requerying the DNS.

On some Java configurations, the JVM default TTL is set so that it never refreshes DNS entries until the JVM is restarted. Thus, if the IP address for an AWS resource changes while your application is still running, it can't use that resource until you manually restart the JVM and the cached IP information is refreshed. In this case, it's crucial to set the JVM's TTL so that it periodically refreshes its cached IP information.

Note

The default TTL can vary according to the version of your JVM and whether a security manager is installed. Many JVMs provide a default TTL less than 60 seconds. If you're using such a JVM and not using a security manager, you can ignore the rest of this topic. For more information on security managers in Oracle, see [The security manager](#) in the Oracle documentation.

To modify the JVM's TTL, set the `networkaddress.cache.ttl` property value. Use one of the following methods, depending on your needs:

- To set the property value globally for all applications that use the JVM, set `networkaddress.cache.ttl` in the `$JAVA_HOME/jre/lib/security/java.security` file.

```
networkaddress.cache.ttl=60
```

- To set the property locally for your application only, set `networkaddress.cache.ttl` in your application's initialization code before any network connections are established.

```
java.security.Security.setProperty("networkaddress.cache.ttl" , "60");
```

DB instance billing for Amazon RDS

Amazon RDS instances are billed based on the following components:

- DB instance hours (per hour) – Based on the DB instance class of the DB instance (for example, db.t2.small or db.m4.large). Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. RDS usage is billed in one second increments, with a minimum of 10 minutes. For more information, see [DB instance classes \(p. 7\)](#).
- Storage (per GiB per month) – Storage capacity that you have provisioned to your DB instance. If you scale your provisioned storage capacity within the month, your bill is pro-rated. For more information, see [Amazon RDS DB instance storage \(p. 40\)](#).
- I/O requests (per 1 million requests per month) – Total number of storage I/O requests that you have made in a billing cycle, for Amazon RDS magnetic storage only.
- Provisioned IOPS (per IOPS per month) – Provisioned IOPS rate, regardless of IOPS consumed, for Amazon RDS Provisioned IOPS (SSD) storage only. Provisioned storage for EBS volumes are billed in one second increments, with a minimum of 10 minutes.
- Backup storage (per GiB per month) – *Backup storage* is the storage that is associated with automated database backups and any active database snapshots that you have taken. Increasing your backup retention period or taking additional database snapshots increases the backup storage consumed by your database. Per second billing doesn't apply to backup storage (metered in GB-month).

For more information, see [Backing up and restoring an Amazon RDS DB instance \(p. 327\)](#).

- Data transfer (per GB) – Data transfer in and out of your DB instance from or to the internet and other AWS Regions.

Amazon RDS provides the following purchasing options to enable you to optimize your costs based on your needs:

- **On-Demand Instances** – Pay by the hour for the DB instance hours that you use. Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. RDS usage is now billed in one second increments, with a minimum of 10 minutes.
- **Reserved Instances** – Reserve a DB instance for a one-year or three-year term and get a significant discount compared to the on-demand DB instance pricing. With Reserved Instance usage, you can launch, delete, start, or stop multiple instances within an hour and get the Reserved Instance benefit for all of the instances.

For Amazon RDS pricing information, see the [Amazon RDS product page](#).

Topics

- [On-Demand DB instances for Amazon RDS \(p. 58\)](#)
- [Reserved DB instances for Amazon RDS \(p. 59\)](#)

On-Demand DB instances for Amazon RDS

Amazon RDS on-demand DB instances are billed based on the class of the DB instance (for example, db.t2.small or db.m4.large). For Amazon RDS pricing information, see the [Amazon RDS product page](#).

Billing starts for a DB instance as soon as the DB instance is available. Pricing is listed on a per-hour basis, but bills are calculated down to the second and show times in decimal form. Amazon RDS usage is billed in one-second increments, with a minimum of 10 minutes. In the case of billable configuration change, such as scaling compute or storage capacity, you're charged a 10-minute minimum. Billing continues until the DB instance terminates, which occurs when you delete the DB instance or if the DB instance fails.

If you no longer want to be charged for your DB instance, you must stop or delete it to avoid being billed for additional DB instance hours. For more information about the DB instance states for which you are billed, see [DB instance status \(p. 404\)](#).

Stopped DB instances

While your DB instance is stopped, you're charged for provisioned storage, including Provisioned IOPS. You are also charged for backup storage, including storage for manual snapshots and automated backups within your specified retention window. You aren't charged for DB instance hours.

Multi-AZ DB instances

If you specify that your DB instance should be a Multi-AZ deployment, you're billed according to the Multi-AZ pricing posted on the Amazon RDS pricing page.

Reserved DB instances for Amazon RDS

Using reserved DB instances, you can reserve a DB instance for a one- or three-year term. Reserved DB instances provide you with a significant discount compared to on-demand DB instance pricing. Reserved DB instances are not physical instances, but rather a billing discount applied to the use of certain on-demand DB instances in your account. Discounts for reserved DB instances are tied to instance type and AWS Region.

The general process for working with reserved DB instances is: First get information about available reserved DB instance offerings, then purchase a reserved DB instance offering, and finally get information about your existing reserved DB instances.

Overview of reserved DB instances

When you purchase a reserved DB instance in Amazon RDS, you purchase a commitment to getting a discounted rate, on a specific DB instance type, for the duration of the reserved DB instance. To use an Amazon RDS reserved DB instance, you create a new DB instance just like you do for an on-demand instance. The new DB instance that you create must match the specifications of the reserved DB instance. If the specifications of the new DB instance match an existing reserved DB instance for your account, you are billed at the discounted rate offered for the reserved DB instance. Otherwise, the DB instance is billed at an on-demand rate.

For more information about reserved DB instances, including pricing, see [Amazon RDS reserved instances](#).

Offering types

Reserved DB instances are available in three varieties—No Upfront, Partial Upfront, and All Upfront—that let you optimize your Amazon RDS costs based on your expected usage.

No Upfront

This option provides access to a reserved DB instance without requiring an upfront payment. Your No Upfront reserved DB instance bills a discounted hourly rate for every hour within the term, regardless of usage, and no upfront payment is required. This option is only available as a one-year reservation.

Partial Upfront

This option requires a part of the reserved DB instance to be paid upfront. The remaining hours in the term are billed at a discounted hourly rate, regardless of usage. This option is the replacement for the previous Heavy Utilization option.

All Upfront

Full payment is made at the start of the term, with no other costs incurred for the remainder of the term regardless of the number of hours used.

If you are using consolidated billing, all the accounts in the organization are treated as one account. This means that all accounts in the organization can receive the hourly cost benefit of reserved DB instances that are purchased by any other account. For more information about consolidated billing, see [Amazon RDS reserved DB instances](#) in the *AWS Billing and Cost Management User Guide*.

Size-flexible reserved DB instances

When you purchase a reserved DB instance, one thing that you specify is the instance class, for example db.m4.large. For more information about instance classes, see [DB instance classes \(p. 7\)](#).

If you have a DB instance, and you need to scale it to larger capacity, your reserved DB instance is automatically applied to your scaled DB instance. That is, your reserved DB instances are automatically

applied across all DB instance class sizes. Size-flexible reserved DB instances are available for DB instances with the same AWS Region and database engine. Size-flexible reserved DB instances can only scale in their instance class type. For example, a reserved DB instance for a db.m4.large can apply to a db.m4.xlarge, but not to a db.m5.large, because db.m4 and db.m5 are different instance class types.

Reserved DB instance benefits also apply for both Multi-AZ and Single-AZ configurations. Flexibility means that you can move freely between configurations within the same DB instance class type. For example, you can move from a Single-AZ deployment running on one large DB instance (four normalized units) to a Multi-AZ deployment running on two small DB instances ($2 \times 2 = 4$ normalized units).

Size-flexible reserved DB instances are available for the following Amazon RDS database engines:

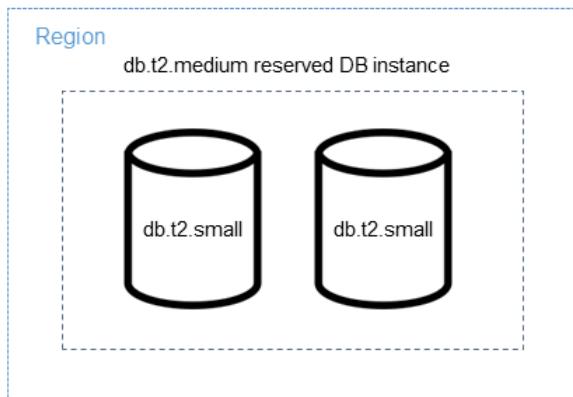

- MariaDB
- MySQL
- Oracle, Bring Your Own License
- PostgreSQL

For details about using size-flexible reserved instances with Aurora, see [Reserved DB instances for Aurora](#).

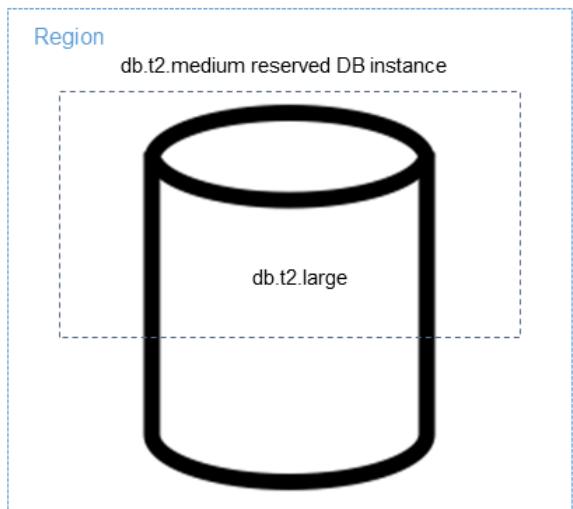

You can compare usage for different reserved DB instance sizes by using normalized units. For example, one unit of usage on two db.m3.large DB instances is equivalent to eight normalized units of usage on one db.m3.small. The following table shows the number of normalized units for each DB instance size.

Instance size	Single-AZ normalized units	Multi-AZ normalized units
micro	0.5	1
small	1	2
medium	2	4
large	4	8
xlarge	8	16
2xlarge	16	32
4xlarge	32	64
6xlarge	48	96
8xlarge	64	128
10xlarge	80	160
12xlarge	96	192
16xlarge	128	256
24xlarge	192	384
32xlarge	256	512

For example, suppose that you purchase a db.t2.medium reserved DB instance, and you have two running db.t2.small DB instances in your account in the same AWS Region. In this case, the billing benefit is applied in full to both instances.

Alternatively, if you have one db.t2.large instance running in your account in the same AWS Region, the billing benefit is applied to 50 percent of the usage of the DB instance.

Reserved DB instance billing example

The price for a reserved DB instance doesn't include regular costs associated with storage, backups, and I/O. The following example illustrates the total cost per month for a reserved DB instance:

- An RDS for MySQL reserved Single-AZ db.r4.large DB instance class in US East (N. Virginia) with the No Upfront option at a cost of \$0.12 for the instance, or \$90 per month
- 400 GiB of General Purpose SSD (gp2) storage at a cost of 0.115 per GiB per month, or \$45.60 per month
- 600 GiB of backup storage at \$0.095, or \$19 per month (400 GiB free)

Add all of these options (\$90 + \$45.60 + \$19) with the reserved DB instance, and the total cost per month is \$154.60.

If you chose to use an on-demand DB instance instead of a reserved DB instance, an RDS for MySQL Single-AZ db.r4.large DB instance class in US East (N. Virginia) costs \$0.1386 per hour, or \$101.18 per month. So, for an on-demand DB instance, add all of these options (\$101.18 + \$45.60 + \$19), and the total cost per month is \$165.78.

Note

The prices in this example are sample prices and might not match actual prices. For Amazon RDS pricing information, see the [Amazon RDS product page](#).

Deleting a reserved DB instance

The terms for a reserved DB instance involve a one-year or three-year commitment. You can't cancel a reserved DB instance. However, you can delete a DB instance that is covered by a reserved DB instance discount. The process for deleting a DB instance that is covered by a reserved DB instance discount is the same as for any other DB instance.

Your upfront payment for a reserved DB instance reserves the resources for your use. Because these resources are reserved for you, you are billed for the resources regardless of whether you use them.

If you delete a DB instance that is covered by a reserved DB instance discount, you can launch another DB instance with compatible specifications. In this case, you continue to get the discounted rate during the reservation term (one or three years).

Working with reserved DB instances

You can use the AWS Management Console, the AWS CLI, and the RDS API to work with reserved DB instances.

Console

You can use the AWS Management Console to work with reserved DB instances as shown in the following procedures.

To get pricing and information about available reserved DB instance offerings

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Reserved instances**.
3. Choose **Purchase Reserved DB Instance**.
4. For **Product description**, choose the DB engine and licensing type.
5. For **DB instance class**, choose the DB instance class.
6. For **Multi-AZ deployment**, choose whether you want a Multi-AZ deployment.
7. For **Term**, choose the length of time you want the DB instance reserved.
8. For **Offering type**, choose the offering type.

After you select the offering type, you can see the pricing information.

Important

Choose **Cancel** to avoid purchasing the reserved DB instance and incurring any charges.

After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering as shown in the following procedure.

To purchase a reserved DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Reserved instances**.

3. Choose **Purchase Reserved DB Instance**.
4. For **Product description**, choose the DB engine and licensing type.
5. For **DB instance class**, choose the DB instance class.
6. For **Multi-AZ deployment**, choose whether you want a Multi-AZ deployment.
7. For **Term**, choose the length of time you want the DB instance reserved.
8. For **Offering type**, choose the offering type.

After you choose the offering type, you can see the pricing information.

RDS > Reserved instances > Purchase Reserved DB Instances

Purchase Reserved DB Instances

Choose from the options below, then enter the number of DB instances you wish to reserve with this order. When you are done, click the Continue button.

Options

Product description: sqlserver-ex(l1)

DB instance class: db.t3.small — 2 vCPU, 2 GiB RAM

Multi AZ deployment: Multi-AZ deployment model is not applicable for this database engine and edition

Term: 1 year

Offering type: Partial Upfront

Reserved Id (optional): Optional tag to track your reservation

Number of DB instances: Specify the number of DB instances you wish to reserve with this order

1

Pricing details

One-time payment (per instance)	Usage charges*
[Redacted]	(hourly) <small>*Additional taxes may apply</small>
Total one-time payment*	This hourly rate is charged for every hour for each instance in the Reserved Instance term you purchase, regardless of instance usage
*Additional taxes may apply	
Charges for your usage will appear on your monthly bill.	

Cancel **Continue**

9. (Optional) You can assign your own identifier to the reserved DB instances that you purchase to help you track them. For **Reserved Id**, type an identifier for your reserved DB instance.
10. Choose **Continue**.

The **Purchase Reserved DB Instances** dialog box appears, with a summary of the reserved DB instance attributes that you've selected and the payment due.

The screenshot shows the 'Purchase Reserved DB Instances' page. At the top, there's a breadcrumb trail: RDS > Reserved instances > Purchase Reserved DB Instances. The main title is 'Purchase Reserved DB Instances'. Below it is a 'Summary of Purchase' section with the following details:

Region	US West (Oregon)
Product Description	sqlserver-ex(l1)
DB Instance Class	db.t3.small
Offering Type	Partial Upfront
Multi AZ Deployment	No
Term	1 year
Reserved DB Instance	default
Quantity	1
Price Per Instance	[Redacted]
Total Payment Due Now	[Redacted]

At the bottom of the summary section, there's a warning message: **⚠️ Purchasing this Reserved DB Instance will charge [Redacted] to the payment method associated with this Amazon Web Services account. Are you sure you would like to proceed?**

At the very bottom right, there are three buttons: 'Cancel', 'Back', and a highlighted orange button labeled 'Order'.

11. On the confirmation page, review your reserved DB instance. If the information is correct, choose **Order** to purchase the reserved DB instance.

Alternatively, choose **Back** to edit your reserved DB instance.

After you have purchased reserved DB instances, you can get information about your reserved DB instances as shown in the following procedure.

To get information about reserved DB instances for your AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the Navigation pane, choose **Reserved instances**.

The reserved DB instances for your account appear. To see detailed information about a particular reserved DB instance, choose that instance in the list. You can then see detailed information about that instance in the detail pane at the bottom of the console.

AWS CLI

You can use the AWS CLI to work with reserved DB instances as shown in the following examples.

Example of getting available reserved DB instance offerings

To get information about available reserved DB instance offerings, call the AWS CLI command [describe-reserved-db-instances-offerings](#).

```
aws rds describe-reserved-db-instances-offerings
```

This call returns output similar to the following:

OFFERING	OfferingId	Class	Multi-AZ	Duration	Fixed
Price	Usage Price	Description	Offering Type		
OFFERING	438012d3-4052-4cc7-b2e3-8d3372e0e706	db.m1.large	y	1y	1820.00
USD	0.368 USD	mysql	Partial Upfront		
OFFERING	649fd0c8-cf6d-47a0-bfa6-060f8e75e95f	db.m1.small	n	1y	227.50
USD	0.046 USD	mysql	Partial Upfront		
OFFERING	123456cd-ab1c-47a0-bfa6-12345667232f	db.m1.small	n	1y	162.00
USD	0.00 USD	mysql	All Upfront		
Recurring Charges:	Amount	Currency	Frequency		
Recurring Charges:	0.123	USD	Hourly		
OFFERING	123456cd-ab1c-37a0-bfa6-12345667232d	db.m1.large	y	1y	700.00
USD	0.00 USD	mysql	All Upfront		
Recurring Charges:	Amount	Currency	Frequency		
Recurring Charges:	1.25	USD	Hourly		
OFFERING	123456cd-ab1c-17d0-bfa6-12345667234e	db.m1.xlarge	n	1y	4242.00
USD	2.42 USD	mysql	No Upfront		

After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering.

To purchase a reserved DB instance, use the AWS CLI command [purchase-reserved-db-instances-offering](#) with the following parameters:

- **--reserved-db-instances-offering-id** – The ID of the offering that you want to purchase. See the preceding example to get the offering ID.
- **--reserved-db-instance-id** – You can assign your own identifier to the reserved DB instances that you purchase to help track them.

Example of purchasing a reserved DB instance

The following example purchases the reserved DB instance offering with ID [649fd0c8-cf6d-47a0-bfa6-060f8e75e95f](#), and assigns the identifier of [MyReservation](#).

For Linux, macOS, or Unix:

```
aws rds purchase-reserved-db-instances-offering \
--reserved-db-instances-offering-id 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f \
--reserved-db-instance-id MyReservation
```

For Windows:

```
aws rds purchase-reserved-db-instances-offering ^
--reserved-db-instances-offering-id 649fd0c8-cf6d-47a0-bfa6-060f8e75e95f ^
--reserved-db-instance-id MyReservation
```

The command returns output similar to the following:

RESERVATION	ReservationId	Class	Multi-AZ	Start Time	Duration
Fixed Price	Usage Price	Count	State	Description	Offering Type
RESERVATION	MyReservation	db.m1.small	y	2011-12-19T00:30:23.247Z	1y
455.00 USD	0.092 USD	1	payment-pending	mysql	Partial Upfront

After you have purchased reserved DB instances, you can get information about your reserved DB instances.

To get information about reserved DB instances for your AWS account, call the AWS CLI command [describe-reserved-db-instances](#), as shown in the following example.

Example of getting your reserved DB instances

```
aws rds describe-reserved-db-instances
```

The command returns output similar to the following:

RESERVATION	ReservationId	Class	Multi-AZ	Start Time	Duration
Fixed Price	Usage Price	Count	State	Description	Offering Type
RESERVATION	MyReservation	db.m1.small	y	2011-12-09T23:37:44.720Z	1y
455.00 USD	0.092 USD	1	retired	mysql	Partial Upfront

RDS API

You can use the RDS API to work with reserved DB instances:

- To get information about available reserved DB instance offerings, call the Amazon RDS API operation [DescribeReservedDBInstancesOfferings](#).
- After you have information about the available reserved DB instance offerings, you can use the information to purchase an offering. Call the [PurchaseReservedDBInstancesOffering](#) RDS API operation with the following parameters:
 - **--reserved-db-instances-offering-id** – The ID of the offering that you want to purchase.
 - **--reserved-db-instance-id** – You can assign your own identifier to the reserved DB instances that you purchase to help track them.
- After you have purchased reserved DB instances, you can get information about your reserved DB instances. Call the [DescribeReservedDBInstances](#) RDS API operation.

Setting up for Amazon RDS

Complete the tasks in this section to set up Amazon Relational Database Service (Amazon RDS) for the first time. If you already have an AWS account, know your Amazon RDS requirements, and prefer to use the defaults for IAM and VPC security groups, skip ahead to [Getting started \(p. 4\)](#).

A couple things you should know about Amazon Web Services (AWS):

- When you sign up for AWS, your AWS account automatically has access to all services in AWS, including Amazon RDS. However, you are charged only for the services that you use.
- With Amazon RDS, you pay only for the RDS instances that are active. The Amazon RDS DB instance that you create is live (not running in a sandbox). You incur the standard Amazon RDS usage fees for the instance until you terminate it. For more information about Amazon RDS usage rates, see the [Amazon RDS product page](#).

Topics

- [Sign up for AWS \(p. 67\)](#)
- [Create an IAM user \(p. 67\)](#)
- [Determine requirements \(p. 69\)](#)
- [Provide access to your DB instance in your VPC by creating a security group \(p. 70\)](#)

Sign up for AWS

If you have an AWS account already, skip to the next section, [Create an IAM user \(p. 67\)](#).

If you don't have an AWS account, you can use the following procedure to create one. If you are a new AWS customer, you can get started with Amazon RDS for free; for more information, see [AWS free usage tier](#).

To create a new AWS account

1. Open <https://portal.aws.amazon.com/billing/signup>.
2. Follow the online instructions.

Part of the sign-up procedure involves receiving a phone call and entering a verification code on the phone keypad.

Create an IAM user

After you create an AWS account and successfully connect to the AWS Management Console, you can create an AWS Identity and Access Management (IAM) user. Instead of signing in with your AWS root account, we recommend that you use an IAM administrative user with Amazon RDS.

One way to do this is to create a new IAM user and grant it administrator permissions. Alternatively, you can add an existing IAM user to an IAM group with Amazon RDS administrative permissions. You can then access AWS from a special URL using the credentials for the IAM user.

If you signed up for AWS but haven't created an IAM user for yourself, you can create one using the IAM console.

To create an administrator user for yourself and add the user to an administrators group (console)

1. Sign in to the [IAM console](#) as the account owner by choosing **Root user** and entering your AWS account email address. On the next page, enter your password.

Note

We strongly recommend that you adhere to the best practice of using the **Administrator** IAM user below and securely lock away the root user credentials. Sign in as the root user only to perform a few [account and service management tasks](#).

2. In the navigation pane, choose **Users** and then choose **Add user**.
3. For **User name**, enter **Administrator**.
4. Select the check box next to **AWS Management Console access**. Then select **Custom password**, and then enter your new password in the text box.
5. (Optional) By default, AWS requires the new user to create a new password when first signing in. You can clear the check box next to **User must create a new password at next sign-in** to allow the new user to reset their password after they sign in.
6. Choose **Next: Permissions**.
7. Under **Set permissions**, choose **Add user to group**.
8. Choose **Create group**.
9. In the **Create group** dialog box, for **Group name** enter **Administrators**.
10. Choose **Filter policies**, and then select **AWS managed -job function** to filter the table contents.
11. In the policy list, select the check box for **AdministratorAccess**. Then choose **Create group**.

Note

You must activate IAM user and role access to Billing before you can use the **AdministratorAccess** permissions to access the AWS Billing and Cost Management console. To do this, follow the instructions in [step 1 of the tutorial about delegating access to the billing console](#).

12. Back in the list of groups, select the check box for your new group. Choose **Refresh** if necessary to see the group in the list.
13. Choose **Next: Tags**.
14. (Optional) Add metadata to the user by attaching tags as key-value pairs. For more information about using tags in IAM, see [Tagging IAM entities](#) in the *IAM User Guide*.
15. Choose **Next: Review** to see the list of group memberships to be added to the new user. When you are ready to proceed, choose **Create user**.

You can use this same process to create more groups and users and to give your users access to your AWS account resources. To learn about using policies that restrict user permissions to specific AWS resources, see [Access management](#) and [Example policies](#).

To sign in as the new IAM user, first sign out of the AWS Management Console. Then use the following URL, where **your_aws_account_id** is your AWS account number without the hyphens. For example, if your AWS account number is 1234-5678-9012, your AWS account ID is 123456789012.

```
https://your_aws_account_id.signin.aws.amazon.com/console/
```

Type the IAM user name and password that you just created. When you're signed in, the navigation bar displays "**your_user_name @ your_aws_account_id**".

If you don't want the URL for your sign-in page to contain your AWS account ID, you can create an account alias. From the IAM dashboard, choose **Customize** and type an alias, such as your company name. To sign in after you create an account alias, use the following URL.

`https://your_account_alias.signin.aws.amazon.com/console/`

To verify the sign-in link for IAM users for your account, open the IAM console and check under **AWS Account Alias** on the dashboard.

You can also create access keys for your AWS account. These access keys can be used to access AWS through the AWS Command Line Interface (AWS CLI) or through the Amazon RDS API. For more information, see [Programmatic access](#), [Installing the AWS CLI](#), and the [Amazon RDS API reference](#).

Determine requirements

The basic building block of Amazon RDS is the DB instance. In a DB instance, you create your databases. A DB instance provides a network address called an *endpoint*. Your applications use this endpoint to connect to your DB instance. When you create a DB instance, you specify details like storage, memory, database engine and version, network configuration, security, and maintenance periods. You control network access to a DB instance through a security group.

Before you create a DB instance and a security group, you must know your DB instance and network needs. Here are some important things to consider:

- **Resource requirements** – What are the memory and processor requirements for your application or service? You use these settings to help you determine what DB instance class to use. For specifications about DB instance classes, see [DB instance classes \(p. 7\)](#).
- **VPC, subnet, and security group** – Your DB instance is most likely in a virtual private cloud (VPC). To connect to your DB instance, you need to set up security group rules. These rules are set up differently depending on what kind of VPC you use and how you use it: in a default VPC, in a user-defined VPC, or outside of a VPC.

Note

Some legacy accounts don't use a VPC. If you are accessing a new AWS Region or you are a new RDS user (after 2013), you are most likely creating a DB instance inside a VPC.

For information on how to determine if your account has a default VPC in a particular AWS Region, see [Determining whether you are using the EC2-VPC or EC2-Classic platform \(p. 1718\)](#).

The following list describes the rules for each VPC option:

- **Default VPC** – If your AWS account has a default VPC in the current AWS Region, that VPC is configured to support DB instances. If you specify the default VPC when you create the DB instance, do the following:
 - Create a *VPC security group* that authorizes connections from the application or service to the Amazon RDS DB instance with the database. Use the [Amazon EC2 API](#) or the **Security Group** option on the VPC console to create VPC security groups. For information, see [Step 4: Create a VPC security group \(p. 1734\)](#).
 - Specify the default DB subnet group. If this is the first DB instance you have created in this AWS Region, Amazon RDS creates the default DB subnet group when it creates the DB instance.
- **User-defined VPC** – If you want to specify a user-defined VPC when you create a DB instance, be aware of the following:
 - Make sure to create a *VPC security group* that authorizes connections from the application or service to the Amazon RDS DB instance with the database. Use the [Amazon EC2 API](#) or the **Security Group** option on the VPC console to create VPC security groups. For information, see [Step 4: Create a VPC security group \(p. 1734\)](#).
 - The VPC must meet certain requirements in order to host DB instances, such as having at least two subnets, each in a separate availability zone. For information, see [Amazon Virtual Private Cloud VPCs and Amazon RDS \(p. 1718\)](#).

- Make sure to specify a DB subnet group that defines which subnets in that VPC can be used by the DB instance. For information, see the DB subnet group section in [Working with a DB instance in a VPC \(p. 1728\)](#).
- **No VPC** – If your AWS account doesn't have a default VPC and you don't specify a user-defined VPC, create a DB security group. A *DB security group* authorizes connections from the devices and Amazon RDS instances running the applications or utilities to access the databases in the DB instance. For more information, see [Working with DB security groups \(EC2-Classic platform\) \(p. 1704\)](#).
- **High availability:** Do you need failover support? On Amazon RDS, a Multi-AZ deployment creates a primary DB instance and a secondary standby DB instance in another Availability Zone for failover support. We recommend Multi-AZ deployments for production workloads to maintain high availability. For development and test purposes, you can use a deployment that isn't Multi-AZ. For more information, see [High availability \(Multi-AZ\) for Amazon RDS \(p. 53\)](#).
- **IAM policies:** Does your AWS account have policies that grant the permissions needed to perform Amazon RDS operations? If you are connecting to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS operations. For more information, see [Identity and access management in Amazon RDS \(p. 1644\)](#).
- **Open ports:** What TCP/IP port does your database listen on? The firewall at some companies might block connections to the default port for your database engine. If your company firewall blocks the default port, choose another port for the new DB instance. When you create a DB instance that listens on a port you specify, you can change the port by modifying the DB instance.
- **AWS Region:** What AWS Region do you want your database in? Having your database in close proximity to your application or web service can reduce network latency.
- **DB disk subsystem:** What are your storage requirements? Amazon RDS provides three storage types:
 - Magnetic (Standard Storage)
 - General Purpose (SSD)
 - Provisioned IOPS (PIOPS)

Magnetic storage offers cost-effective storage that is ideal for applications with light or burst I/O requirements. General purpose, SSD-backed storage, also called *gp2*, can provide faster access than disk-based storage. Provisioned IOPS storage is designed to meet the needs of I/O-intensive workloads, particularly database workloads, which are sensitive to storage performance and consistency in random access I/O throughput. For more information on Amazon RDS storage, see [Amazon RDS DB instance storage \(p. 40\)](#).

When you have the information you need to create the security group and the DB instance, continue to the next step.

Provide access to your DB instance in your VPC by creating a security group

VPC security groups provide access to DB instances in a VPC. They act as a firewall for the associated DB instance, controlling both inbound and outbound traffic at the instance level. DB instances are created by default with a firewall and a default security group that protect the DB instance.

Before you can connect to your DB instance, you must add rules to security group that enable you to connect. Use your network and configuration information to create rules to allow access to your DB instance.

Note

If your legacy DB instance was created before March 2013 and isn't in a VPC, it might not have associated security groups. If your DB instance was created after this date, it might be inside a default VPC.

For example, suppose that you have an application that accesses a database on your DB instance in a VPC. In this case, you must add a custom TCP rule that specifies the port range and IP addresses that your application uses to access the database. If you have an application on an Amazon EC2 instance, you can use the security group that you set up for the Amazon EC2 instance.

To create a VPC security group

1. Sign in to the AWS Management Console and open the Amazon VPC console at <https://console.aws.amazon.com/vpc>.
2. In the top right corner of the AWS Management Console, choose the AWS Region where you want to create your VPC security group and DB instance. In the list of Amazon VPC resources for that AWS Region, you should see at least one VPC and several subnets. If you don't, you don't have a default VPC in that AWS Region.
3. In the navigation pane, choose **Security Groups**.
4. Choose **Create Security Group**.
5. In the **Create Security Group** window, type **Name tag**, **Group name**, and **Description** values for your security group. For **VPC**, choose the VPC that you want to create your DB instance in. Choose **Yes, Create**.
6. The VPC security group that you created should still be selected. If not, locate it in the list, and choose it. The details pane at the bottom of the console window displays the details for the security group, and tabs for working with inbound and outbound rules. Choose the **Inbound Rules** tab.
7. On the **Inbound Rules** tab, choose **Edit**.
 - a. For **Type**, choose **Custom TCP Rule**.
 - b. For **Port Range**, type the port value to use for your DB instance.
 - c. For **Source**, choose a security group name or type the IP address range (CIDR value) from where you access the instance. If you choose **My IP**, this allows access to the DB instance from the IP address detected in your browser.
8. Choose **Add another rule** if you need to add more IP addresses or different port ranges.
9. (Optional) Use the **Outbound Rules** tab to add rules for outbound traffic. By default, all outbound traffic is allowed.

You can use the VPC security group that you just created as the security group for your DB instance when you create it. If your DB instance isn't going to be in a VPC, see [Working with DB security groups \(EC2-Classic platform\) \(p. 1704\)](#) to create a DB security group to use when you create your DB instance.

Note

If you use a default VPC, a default subnet group spanning all of the VPC's subnets is created for you. When you create a DB instance, you can select the default VPC and use **default for DB Subnet Group**.

Once you have completed the setup requirements, you can launch a DB instance using your requirements and security group. For information on creating a DB instance, see the relevant documentation in the following table.

Database engine	Documentation
MariaDB	Creating a MariaDB DB instance and connecting to a database on a MariaDB DB instance (p. 73)
Microsoft SQL Server	Creating a Microsoft SQL Server DB instance and connecting to it (p. 80)
MySQL	Creating a MySQL DB instance and connecting to a database on a MySQL DB instance (p. 86)

Database engine	Documentation
Oracle	Creating an Oracle DB instance and connecting to a database on an Oracle DB instance (p. 93)
PostgreSQL	Creating a PostgreSQL DB instance and connecting to a database on a PostgreSQL DB instance (p. 99)

Note

If you can't connect to a DB instance after you create it, see the troubleshooting information in [Can't connect to Amazon RDS DB instance \(p. 1746\)](#).

Getting started with Amazon RDS

In the following examples, you can find how to create and connect to a DB instance using Amazon Relational Database Service (Amazon RDS). You can create a DB instance that uses MariaDB, MySQL, Microsoft SQL Server, Oracle, or PostgreSQL.

Important

Before you can create or connect to a DB instance, you must complete the tasks in [Setting up for Amazon RDS \(p. 67\)](#).

Creating a DB instance and connecting to a database on a DB instance is slightly different for each of the DB engines. Choose one of the following DB engines that you want to use for detailed information on creating and connecting to the DB instance. After you have created and connected to your DB instance, there are instructions to help you delete the DB instance.

Topics

- [Creating an Oracle DB instance and connecting to a database on an Oracle DB instance \(p. 93\)](#)
- [Creating a PostgreSQL DB instance and connecting to a database on a PostgreSQL DB instance \(p. 99\)](#)
- [Tutorial: Create a web server and an Amazon RDS DB instance \(p. 108\)](#)

Creating a MariaDB DB instance and connecting to a database on a MariaDB DB instance

The easiest way to create a MariaDB DB instance is to use the Amazon RDS console. After you create the DB instance, you can use command line tools such as mysql or standard graphical tools such as HeidiSQL to connect to a database on the DB instance.

Important

Before you can create or connect to a DB instance, you must complete the tasks in [Setting up for Amazon RDS \(p. 67\)](#).

Topics

- [Creating a MariaDB DB instance \(p. 73\)](#)
- [Connecting to a database on a DB instance running the MariaDB database engine \(p. 77\)](#)
- [Deleting a DB instance \(p. 79\)](#)

Creating a MariaDB DB instance

The basic building block of Amazon RDS is the DB instance. This environment is where you run your MariaDB databases.

Console

You can create a DB instance running MariaDB with the AWS Management Console with **Easy Create** enabled or not enabled. With **Easy Create** enabled, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy Create** uses the default setting for other configuration options. With **Easy Create** not enabled, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

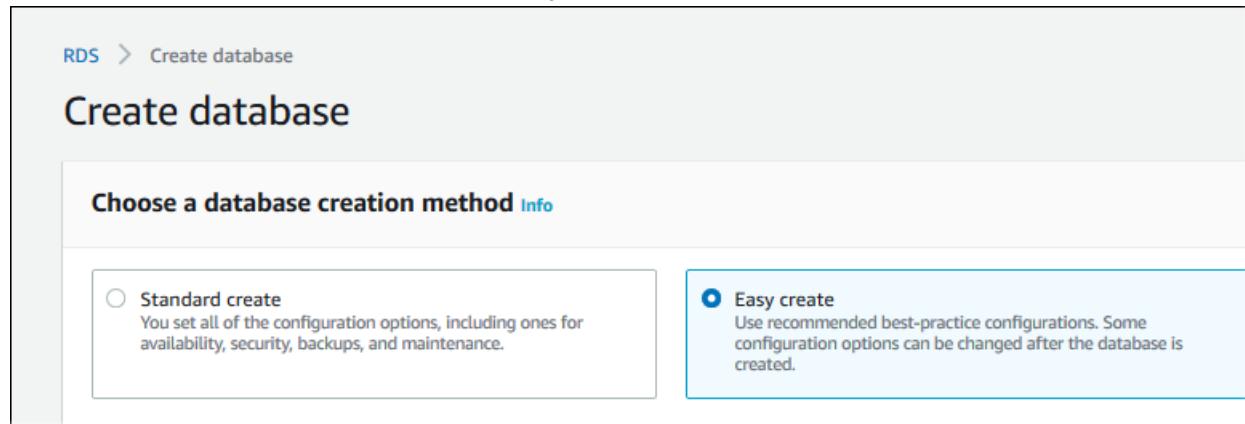

In this example, you use **Easy Create** to create a DB instance running the MariaDB database engine with a db.t2.micro DB instance class.

Note

For information about creating DB instances with **Easy Create** not enabled, see [Creating an Amazon RDS DB instance \(p. 141\)](#).

To create a MariaDB DB instance with Easy Create enabled

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy Create** is chosen.

5. In **Configuration**, choose **MariaDB**.
6. For **DB instance size**, choose **Free tier**.
7. For **DB instance identifier**, enter a name for the DB instance, or leave the default name.
8. For **Master username**, enter a name for the master user, or leave the default name.

The **Create database** page should look similar to the following image.

Create database

Choose a database creation method [Info](#)

Standard Create

You set all of the configuration options, including ones for availability, security, backups, and maintenance.

Easy Create

Use recommended best-practice configuration options can be changed after the database is created.

Configuration

Engine type [Info](#)

Amazon Aurora

4 vCPUs
30.5 GiB RAM
500 GiB

Dev/Test

db.r4.large
2 vCPUs
15.25 GiB RAM
100 GiB

Free tier

db.t2.micro
1 vCPUs
1 GiB RAM
20 GiB

DB instance identifier

Type a name for your DB instance. The name must be unique across all DB instances owned by your AWS account in this Region.

75

database-1

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1–63 characters, alphanumeric (A–Z, a–z, 0–9), and underscores (_).

9. To use an automatically generated master password for the DB instance, make sure that the **Auto generate a password** check box is chosen.

To enter your master password, clear the **Auto generate a password** check box, and then enter the same password in **Master password** and **Confirm password**.

10. (Optional) Open **View default settings for Easy create**.

▼ View default settings for Easy create

Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use [Standard Create](#).

Configuration	Value	Editable after database is created
Encryption	Enabled	No
VPC	Default VPC (vpc-1234567a)	No
Option Group	default:oracle-se2-19	Yes
Subnet Group	default-vpc-1234567a	Yes
Automatic Backups	Enabled	Yes
VPC Security Group	sg-1a2bcd3e	Yes
Publicly Accessible	No	Yes
Database Port	1521	Yes

You can examine the default settings used when **Easy Create** is enabled. If you want to change one or more settings during database creation, choose **Standard Create** to set them. The **Editable after database creation** column shows which options you can change after database creation. To change a setting with **No** in that column, use **Standard Create**. For settings with **Yes** in that column, you can either use **Standard Create** or modify the DB instance after it's created to change the setting.

11. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB instance, choose **View credential details**.

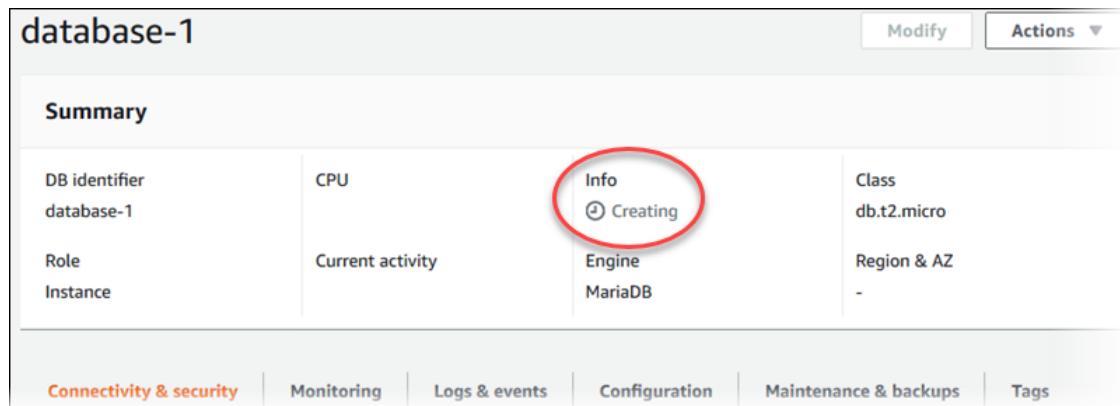

To connect to the DB instance as the master user, use the user name and password that appear.

Important

You can't view the master user password again. If you don't record it, you might have to change it. If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

12. For **Databases**, choose the name of the new Maria DB instance.

On the RDS console, the details for new DB instance appear. The DB instance has a status of **creating** until the DB instance is ready to use. When the state changes to **available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

Connecting to a database on a DB instance running the MariaDB database engine

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to a database on the DB instance. In this example, you connect to a database on a Maria DB instance using the mysql command-line tool. One GUI-based application you can use to connect is HeidiSQL. For more information, see the [Download HeidiSQL](#) page. For more information on using MariaDB, see the [MariaDB documentation](#).

To connect to a database on a DB instance using the mysql command-line tool

1. Find the endpoint (DNS name) and port number for your DB instance.
 - a. Open the RDS console and then choose **Databases** to display a list of your DB instances.
 - b. Choose the Maria DB instance name to display its details.
 - c. On the **Connectivity & security** tab, copy the endpoint. Also note the port number. You need both the endpoint and the port number to connect to the DB instance.

The screenshot shows the Amazon RDS console interface. At the top, the navigation path is RDS > Databases > mydb. Below this, the database name "mydb" is displayed in large blue text. A "Summary" section provides key metrics: DB identifier (mydb), Role (Instance), CPU usage (2.33%), and Current activity (0 Connections). Below the summary, there are tabs for Connectivity & security, Monitoring, Logs & events, and Configuration. The Connectivity & security tab is selected. Under this tab, the "Endpoint & port" section is highlighted with a red oval. It shows the Endpoint as "mydb.us-east-1.rds.amazonaws.com" and the Port as "3306".

2. Enter the following command at a command prompt on a client computer to connect to a database on a Maria DB instance. Substitute the DNS name (endpoint) for your DB instance for <endpoint>, the master user name you used for <mymasteruser>, and provide the master password you used when prompted for a password.

```
PROMPT> mysql -h <endpoint> -P 3306 -u <mymasteruser> -p
```

After you enter the password for the user, you should see output similar to the following.

```
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 272
Server version: 5.5.5-10.0.17-MariaDB-log MariaDB Server

Copyright (c) 2000, 2015, Oracle and/or its affiliates. All rights reserved.

Oracle is a registered trademark of Oracle Corporation and/or its
affiliates. Other names may be trademarks of their respective
owners.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

mysql >
```

For more information about connecting to a MariaDB DB instance, see [Connecting to a DB instance running the MariaDB database engine \(p. 588\)](#). For information on connection issues, see [Can't connect to Amazon RDS DB instance \(p. 1746\)](#).

Deleting a DB instance

After you have connected to the sample DB instance that you created, you should delete the DB instance so you are no longer charged for it.

To delete a DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance you want to delete.
4. For **Actions**, choose **Delete**.
5. For **Create final snapshot?**, choose **No**, and select the acknowledgment.
6. Choose **Delete**.

Creating a Microsoft SQL Server DB instance and connecting to it

The basic building block of Amazon RDS is the DB instance. Your Amazon RDS DB instance is similar to your on-premises Microsoft SQL Server. After you create your SQL Server DB instance, you can add one or more custom databases to it.

Important

You must have an AWS account before you can create a DB instance. If you don't have an AWS account, open <https://aws.amazon.com/>, and then choose **Create an AWS Account**.

In this topic, you create a sample SQL Server DB instance. You then connect to the DB instance and run a simple query. Finally, you delete the sample DB instance.

Creating a sample SQL Server DB instance

You can create a DB instance running Microsoft SQL Server with the AWS Management Console with **Easy create** enabled or not enabled. With **Easy create** enabled, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default settings for other configuration options. With **Easy create** not enabled (**Standard create**), you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

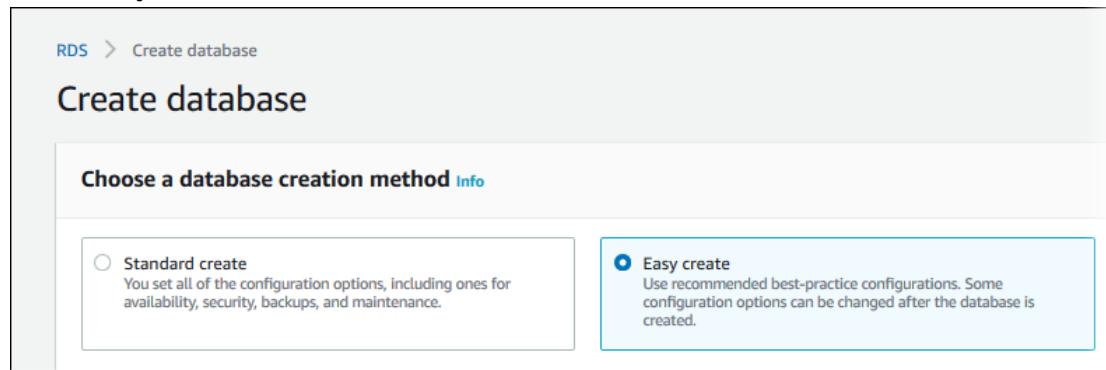

For this example, you use **Easy create** to create a DB instance running SQL Server Express Edition with a db.t2.micro DB instance class.

Note

For information about creating DB instances with **Standard create**, see [Creating an Amazon RDS DB instance \(p. 141\)](#).

To create a Microsoft SQL Server DB instance with Easy create

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. Choose **Easy create**.

6. From **Engine type**, choose **Microsoft SQL Server**.
7. For **DB instance size**, choose **Free tier**.

8. For **DB instance identifier**, enter a name for the DB instance, or leave the default name.
9. For **Master username**, enter a name for the master user, or leave the default name.
10. To use an automatically generated master password for the DB instance, choose the **Auto generate a password** check box.

To enter your master password, clear the **Auto generate a password** check box, and then enter the same password in **Master password** and **Confirm password**.

The **Create database** page should look similar to the following image.

Create database

Cancel **Create database**

11. (Optional) Expand **View default settings for Easy create**.

▼ View default settings for Easy create		
Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use Standard Create .		
Configuration	Value	Editable after database is created
Encryption	Enabled	No
VPC	Default VPC (vpc- [REDACTED])	No
Option Group	defaultsqlserver-ex-14-00	Yes
Subnet Group	default	Yes
Automatic Backups	Enabled	Yes
VPC Security Group	sg- [REDACTED]	Yes
Publicly Accessible	No	Yes
Database Port	1433	Yes
DB Instance Identifier	database-2	Yes
DB Engine Version	14.00.3356.20.v1	Yes
DB Parameter Group	default.sqlserver-ex-14.0	Yes
Performance Insights	Enabled	Yes
Monitoring	Enabled	Yes
Maintenance	Auto Minor Version Upgrade Enabled	Yes
Delete Protection	Not Enabled	Yes

You can examine the default settings used when **Easy create** is enabled. If you want to change one or more settings during database creation, choose **Standard create** to set them. The **Editable after database is created** column shows which options you can change after database creation. To change a setting with **No** in that column, use **Standard create**. For settings with **Yes** in that column, you can either use **Standard create** or modify the DB instance after it's created to change the setting.

12. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB instance, choose **View credential details**.

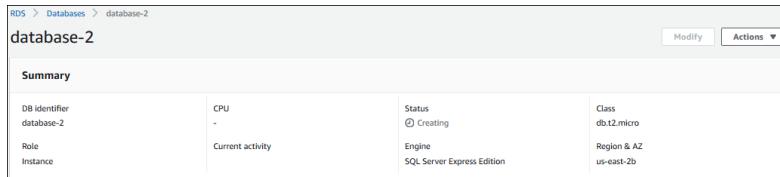

To connect to the DB instance as the master user, use the user name and password that appear.

Important

You can't view the master user password again. If you don't record it, you might have to change it. If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

13. For **Databases**, choose the name of the new Microsoft SQL Server DB instance.

On the RDS console, the details for new DB instance appear. The DB instance has a status of **creating** until the DB instance is ready to use. When the state changes to **available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

Summary			
DB identifier	CPU	Status	Class
database-2	-	Creating	db.t2.micro
Role	Current activity	Engine	Region & AZ
Instance		SQL Server Express Edition	us-east-2b

Connecting to your sample SQL Server DB instance

In this procedure, you connect to your sample DB instance by using Microsoft SQL Server Management Studio (SSMS).

Before you begin, your database should have a status of **Available**. If it has a status of **Creating** or **Backing-up**, wait until it's **Available**. The status updates without requiring you to refresh the page. This process can take up to 20 minutes.

Also, make sure you have SSMS installed. If you can also connect to SQL Server on RDS by using a different tools, such as an add-in for your development environment or some other database tool. However, this tutorial only covers using SSMS. To download a stand-alone version of this SSMS, see [Download SQL Server Management Studio \(SSMS\)](#) in the Microsoft documentation.

To connect to a DB instance using SSMS

1. Find the DNS name and port number for your DB instance.
 - a. Open the RDS console, and then choose **Databases** to display a list of your DB instances.
 - b. Hover your mouse cursor over the name **sample-instance**, which is blue. When you do this, the mouse cursor changes into a selection icon (for example, a pointing hand). Also, the DB instance name, becomes underlined.

Click on the DB instance name to choose it. The screen changes to display the information for the DB instance you choose.
- c. On the **Connectivity** tab, which opens by default, copy the endpoint. The **Endpoint** looks something like this: `sample-instance.abc2defghije.us-west-2.rds.amazonaws.com`. Also, take note of the port number. The default port for SQL Server is 1433. If yours is different, write it down.

2. Start SQL Server Management Studio.

The **Connect to Server** dialog box appears.

3. Provide the information for your sample DB instance.
 - a. For **Server type**, choose **Database Engine**.
 - b. For **Server name**, enter the DNS name, followed by a comma and the port number (the default port is 1433). For example, your server name should look like the following.

`sample-instance.abc2defghije.us-west-2.rds.amazonaws.com,1433`

- c. For **Authentication**, choose **SQL Server Authentication**.
- d. For **Login**, enter the user name that you chose to use for your sample DB instance. This is also known as the master user name.
- e. For **Password**, enter the password that you chose earlier for your sample DB instance. This is also known as the master user password.

4. Choose **Connect**.

After a few moments, SSMS connects to your DB instance.

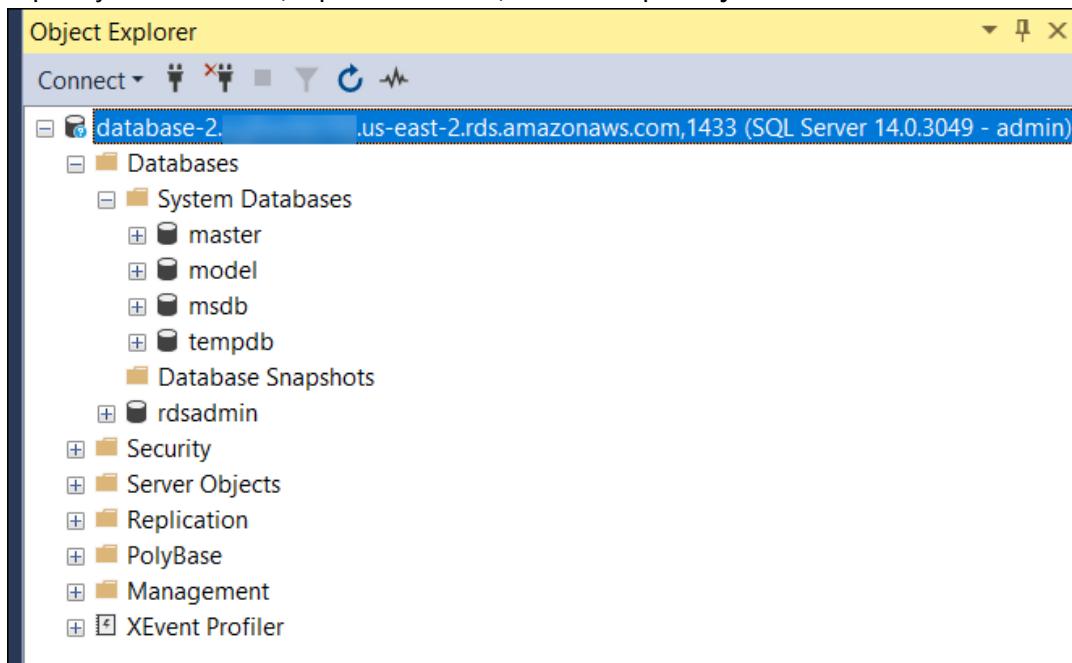

If you can't connect to your DB instance, see [Troubleshooting connections to your SQL Server DB instance \(p. 661\)](#).

Exploring your sample SQL Server DB instance

In this procedure, you continue the previous procedure and explore your sample DB instance by using Microsoft SQL Server Management Studio (SSMS).

To explore a DB instance using SSMS

1. Your SQL Server DB instance comes with SQL Server's standard built-in system databases (master, model, msdb, and tempdb). To explore the system databases, do the following:
 - a. In SSMS, on the **View** menu, choose **Object Explorer**.
 - b. Expand your DB instance, expand **Databases**, and then expand **System Databases** as shown.

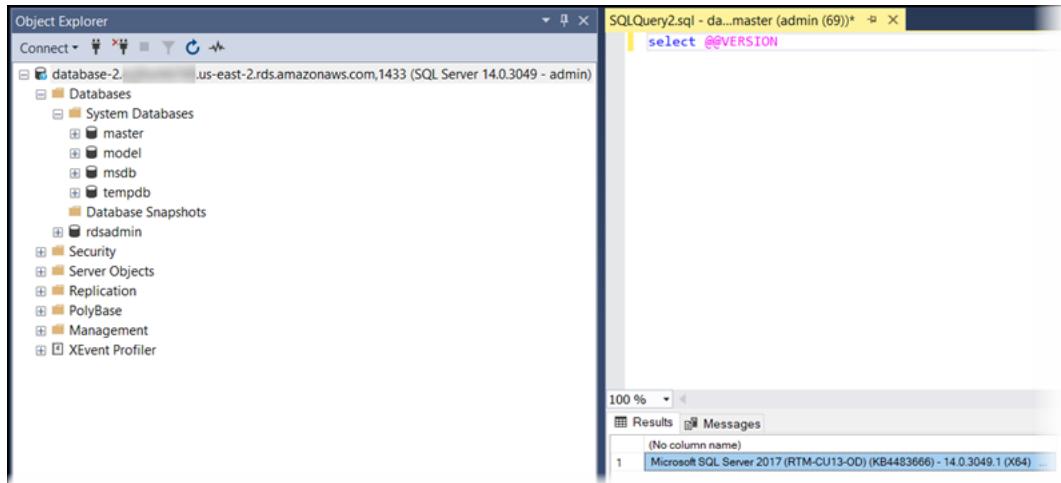

2. Your SQL Server DB instance also comes with a database named `rdsadmin`. Amazon RDS uses this database to store the objects that it uses to manage your database. The `rdsadmin` database also includes stored procedures that you can run to perform advanced tasks.
3. You can now start creating your own databases and running queries against your DB instance and databases as usual. To run a test query against your sample DB instance, do the following:

- a. In SSMS, on the **File** menu point to **New** and then choose **Query with Current Connection**.
- b. Enter the following SQL query.

```
select @@VERSION
```

- c. Run the query. SSMS returns the SQL Server version of your Amazon RDS DB instance.

Deleting your sample DB instance

After you are done exploring the sample DB instance that you created, you should delete the DB instance so that you are no longer charged for it.

To delete a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the button next to **sample-instance**, or whatever you named your sample DB instance.
4. From **Actions**, choose **Delete**.
5. If you see a message that says **This database has deletion protection option enabled**, follow these steps:
 - a. Choose **Modify**.
 - b. On the **Deletion protection** card (near the bottom of the page), clear the box next to **Enable deletion protection**. Then choose **Continue**.
 - c. On the **Scheduling of modifications** card, choose **Apply immediately**. Then choose **Modify DB instance**.
 - d. Try again to delete the instance by choosing **Delete** from the **Actions** menu.
6. Clear the box for **Create final snapshot**. Because this isn't a production database, you don't need to save a copy of it.
7. Verify that you selected the correct database to delete. The name "sample-instance" displays in the title of the screen: **Delete sample-instance instance?**

If you don't recognize the name of your sample instance in the title, choose **Cancel** and start over.

8. To confirm that you want to permanently delete the database that is displayed in the title of this screen, do the following:
 - Check the box to confirm: **I acknowledge that upon instance deletion, automated backups, including system snapshots and point-in-time recovery, will no longer be available.**
 - Type "**delete me**" into the box **To confirm deletion, type *delete me* into the field**.
 - Choose **Delete**. This action can't be undone.

The database shows a status of **Deleting** until deletion is complete.

Creating a MySQL DB instance and connecting to a database on a MySQL DB instance

The easiest way to create a DB instance is to use the AWS Management Console. After you have created the DB instance, you can use standard MySQL utilities such as MySQL Workbench to connect to a database on the DB instance.

Important

Before you can create or connect to a DB instance, you must complete the tasks in [Setting up for Amazon RDS \(p. 67\)](#).

Topics

- [Creating a MySQL DB instance \(p. 86\)](#)
- [Connecting to a database on a DB instance running the MySQL database engine \(p. 90\)](#)
- [Deleting a DB instance \(p. 92\)](#)

Creating a MySQL DB instance

The basic building block of Amazon RDS is the DB instance. This environment is where you run your MySQL databases.

Console

You can create a DB instance running MySQL with the AWS Management Console with **Easy Create** enabled or disabled. With **Easy Create** enabled, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy Create** uses the default setting for other configuration options. With **Easy Create** not enabled, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

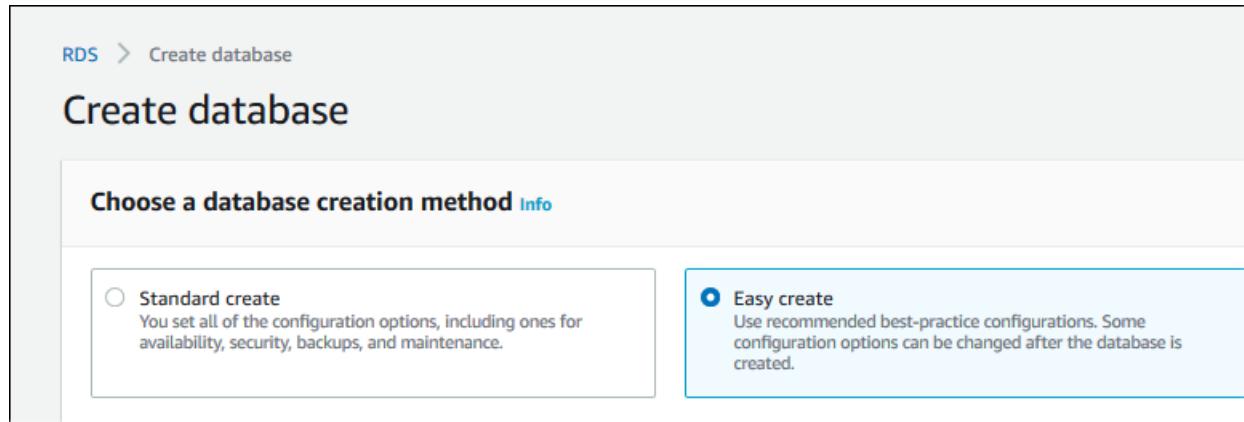

In this example, you use **Easy Create** to create a DB instance running the MySQL database engine with a db.t2.micro DB instance class.

Note

For information about creating DB instances with **Easy Create** not enabled, see [Creating an Amazon RDS DB instance \(p. 141\)](#).

To create a MySQL DB instance with Easy Create enabled

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy Create** is chosen.

5. In **Configuration**, choose **MySQL**.
6. For **DB instance size**, choose **Free tier**.
7. For **DB instance identifier**, enter a name for the DB instance, or leave the default name.
8. For **Master username**, enter a name for the master user, or leave the default name.

The **Create database** page should look similar to the following image.

Create database

Choose a database creation method Info

Standard Create

You set all of the configuration options, including ones for availability, security, backups, and maintenance.

Easy Create

Use recommended best-practice configuration options can be changed after the database is created.

DB instance identifier

Type a name for your DB instance. The name must be unique across all DB instances owned by your AWS account.

Region. 88

database-1

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1

9. To use an automatically generated master password for the DB instance, enable **Auto generate a password**.

To enter your master password, disable **Auto generate a password**, and then enter the same password in **Master password** and **Confirm password**.

10. (Optional) Open **View default settings for Easy create**.

▼ View default settings for Easy create

Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use [Standard Create](#).

Configuration	Value	Editable after database is created
Encryption	Enabled	No
VPC	Default VPC (vpc-1234567a)	No
Option Group	default:oracle-se2-19	Yes
Subnet Group	default-vpc-1234567a	Yes
Automatic Backups	Enabled	Yes
VPC Security Group	sg-1a2bcd3e	Yes
Publicly Accessible	No	Yes
Database Port	1521	Yes

You can examine the default settings used when **Easy Create** is enabled. If you want to change one or more settings during database creation, choose **Standard Create** to set them. The **Editable after database creation** column shows which options you can change after database creation. To change a setting with **No** in that column, use **Standard Create**. For settings with **Yes** in that column, you can either use **Standard Create** or modify the DB instance after it is created to change the setting.

11. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master username and password for the DB instance, choose **View credential details**.

You can use the username and password that appears to connect to the DB instance as the master user.

Important

You won't be able to view master user password again. If you don't record it, you might have to change it. If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

12. In the **Databases** list, choose the name of the new MySQL DB instance.

On the RDS console, the details for new DB instance appear. The DB instance has a status of **creating** until the DB instance is ready to use. When the state changes to **available**, you can connect to the

DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

database-1		Modify	Actions ▾
Summary			
DB identifier database-1	CPU	Info  Creating	Class db.t2.micro
Role Instance	Current activity	Engine MySQL	Region & AZ -

Connecting to a database on a DB instance running the MySQL database engine

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to a database on the DB instance. In this example, you connect to a database on a MySQL DB instance using MySQL monitor commands. One GUI-based application you can use to connect is MySQL Workbench; for more information, go to the [Download MySQL Workbench](#) page. For more information on using MySQL, go to the [MySQL documentation](#). For information about installing MySQL (including the MySQL client), see [Installing and upgrading MySQL](#).

To connect to a database on a DB instance using MySQL monitor

1. Find the endpoint (DNS name) and port number for your DB instance.
 - a. Open the RDS console and then choose **Databases** to display a list of your DB instances.
 - b. Choose the MySQL DB instance name to display its details.
 - c. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

The screenshot shows the Amazon RDS console interface. At the top, the navigation path is RDS > Databases > mydb. Below this, the database identifier is listed as "mydb". On the right side, there are performance metrics: CPU usage at 2.33% and 0 connections. The "Role" is listed as "Instance". At the bottom, there are tabs for Connectivity & security, Monitoring, Logs & events, and Configuration. The Connectivity & security tab is selected. Under this tab, the endpoint and port information is displayed. The endpoint is "mydb.us-east-1.rds.amazonaws.com" and the port is "3306". Both the endpoint and port fields are circled in red.

2. Download a SQL client that you can use to connect to the DB instance.

You can connect to a MySQL DB instance by using tools like the MySQL command line utility. For more information on using the MySQL client, go to [mysql - the MySQL command-line client](#) in the MySQL documentation. One GUI-based application you can use to connect is MySQL Workbench. For more information, go to the [Download MySQL Workbench](#) page.

3. Connect to the a database on a MySQL DB instance. For example, enter the following command at a command prompt on a client computer to connect to a database on a MySQL DB instance using the MySQL client. Substitute the DNS name for your DB instance for `<endpoint>`, the master user name you used for `<mymasteruser>`, and provide the master password you used when prompted for a password.

```
PROMPT> mysql -h <endpoint> -P 3306 -u <mymasteruser> -p
```

After you enter the password for the user, you should see output similar to the following.

```
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 350
Server version: 5.6.40-log MySQL Community Server (GPL)

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

If you can't connect to your MySQL DB instance, two common causes of connection failures to a new DB instance are:

- The DB instance was created using a security group that does not authorize connections from the device or Amazon EC2 instance where the MySQL application or utility is running. If the DB instance was created in a VPC, it must have a VPC security group that authorizes the connections. If the DB instance was created outside of a VPC, it must have a DB security group that authorizes the connections. For more information, see [Amazon Virtual Private Cloud VPCs and Amazon RDS \(p. 1718\)](#).
- The DB instance was created using the default port of 3306, and your company has firewall rules blocking connections to that port from devices in your company network. To fix this failure, recreate the instance with a different port.

For more information about connecting to a MySQL DB instance, see [Connecting to a DB instance running the MySQL database engine \(p. 840\)](#). For information on connection issues, see [Can't connect to Amazon RDS DB instance \(p. 1746\)](#).

Deleting a DB instance

After you have connected to the sample DB instance that you created, you should delete the DB instance so you are no longer charged for it.

To delete a DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to delete.
4. For **Actions**, choose **Delete**.
5. For **Create final snapshot?**, choose **No**, and select the acknowledgment.
6. Choose **Delete**.

Creating an Oracle DB instance and connecting to a database on an Oracle DB instance

The basic building block of Amazon RDS is the DB instance. Your Amazon RDS DB instance is similar to your on-premises Oracle database.

Important

You must have an AWS account before you can create a DB instance. If you don't have an AWS account, open <https://aws.amazon.com/>, and then choose **Create an AWS Account**.

In this topic, you create a sample Oracle DB instance. You then connect to the DB instance and run a simple query. Finally, you delete the sample DB instance.

Creating a sample Oracle DB instance

The DB instance is where you run your Oracle databases.

Console

You can create a DB instance running Oracle with the AWS Management Console with **Easy create** enabled or not enabled. With **Easy create** enabled, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy create** uses the default setting for other configuration options. With **Easy create** not enabled, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

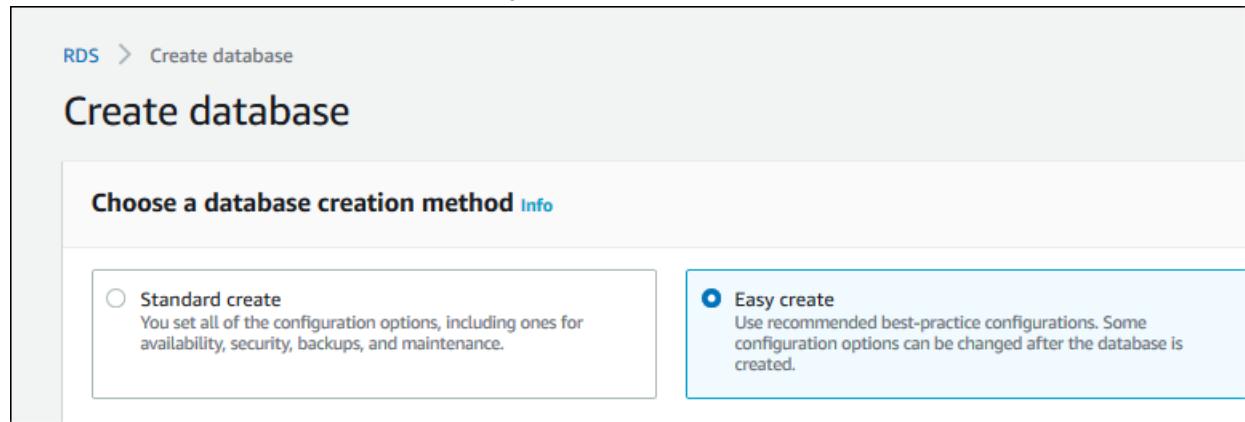

For this example, you use **Easy create** to create a DB instance running the Oracle database engine with a db.m4.large DB instance class.

Note

For information about creating DB instances with **Easy create** not enabled, see [Creating an Amazon RDS DB instance \(p. 141\)](#).

To create an Oracle DB instance with Easy create enabled

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and ensure that **Easy create** is chosen.

5. In **Configuration**, choose **Oracle**.
6. For **DB instance size**, choose **Free tier**. If **Free tier** isn't available, choose **Dev/Test**.
7. For **DB instance identifier**, enter a name for the DB instance, or leave the default name.
8. For **Master username**, enter a name for the master user, or leave the default name.

The **Create database** page should look similar to the following image.

Create database

Choose a database creation method Info

Standard Create

You set all of the configuration options, including ones for availability, security, backups, and maintenance.

Easy Create

Use recommended best-practice configuration options can be changed after the database is created.

9. To use an automatically generated master password for the DB instance, make sure that the **Auto generate a password** check box is chosen.

To enter your master password, clear the **Auto generate a password** check box, and then enter the same password in **Master password** and **Confirm password**.

10. (Optional) Open **View default settings for Easy create**.

▼ View default settings for Easy create

Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use [Standard Create](#).

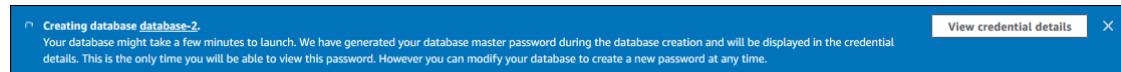

Configuration	Value	Editable after database is created
Encryption	Enabled	No
VPC	Default VPC (vpc-1234567a)	No
Option Group	default:oracle-se2-19	Yes
Subnet Group	default-vpc-1234567a	Yes
Automatic Backups	Enabled	Yes
VPC Security Group	sg-1a2bcd3e	Yes
Publicly Accessible	No	Yes
Database Port	1521	Yes

You can examine the default settings that are used when **Easy create** is enabled. If you want to change one or more settings during database creation, choose **Standard create** to set them. The **Editable after database creation** column shows which options you can change after database creation. To change a setting with **No** in that column, use **Standard create**. For settings with **Yes** in that column, you can either use **Standard create** or modify the DB instance after it's created to change the setting.

11. Choose **Create database**.

If you used an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

Important

You can't view the master user password again. If you don't record it, you might have to change it. If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

12. For **Databases**, choose the name of the new Oracle DB instance.

On the RDS console, the details for new DB instance appear. The DB instance has a status of **creating** until the DB instance is ready to use. When the state changes to **available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

The screenshot shows the 'Summary' tab of the RDS instance details for 'database-1'. The 'Info' column displays the status as 'Creating', which is highlighted with a red circle. Other visible details include the DB identifier 'database-1', CPU usage, role 'Instance', current activity with 0 sessions, engine 'Oracle Enterprise Edition', and class 'db.m5.xlarge'. Below the summary, there are tabs for Connectivity & security, Monitoring, Logs & events, Configuration, Maintenance & backups, and Tags.

Connecting to your sample Oracle DB instance

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the DB instance. In this procedure, you connect to your sample DB instance by using the Oracle sqlplus command line utility. To download a stand-alone version of this utility, see [SQL*Plus User's Guide and Reference](#).

To connect to a DB instance using SQL*Plus

1. Find the endpoint (DNS name) and port number for your DB Instance.
 - a. Open the RDS console and then choose **Databases** to display a list of your DB instances.
 - b. Choose the Oracle DB instance name to display its details.
 - c. On the **Connectivity & security** tab, copy the following pieces of information:
 - Endpoint
 - Port

You need both the endpoint and the port number to connect to the DB instance.

DB identifier	CPU	Status	Class
database-1	<div style="width: 2.3%;">2.30%</div>	Available	db.m4.large
Role	Current activity	Engine	Region & AZ
Instance	<div style="width: 0.01%;">0.01 Sessions</div>	Oracle Standard Edition Two	us-east-1f

Connectivity & security

Endpoint & port	Networking	Security
Endpoint database-1.abcdefghijkl.us-east-1.rds.amazonaws.com	Availability zone us-east-1f	VPC security groups default (sg-0a5cba2b) (active)
Port 1521	VPC vpc-1234567f	Public accessibility No
	Subnet group	

- d. On the **Configuration** tab, copy the following pieces of information:

- DB name (not the DB instance ID)
- Master username

You need both the DB name and the master username to connect to the DB instance.

2. Enter the following command on one line at a command prompt to connect to your DB instance by using the sqlplus utility. Use the following values:
- For **dbuser**, enter the name of the master user that you copied in the preceding steps.
 - For **HOST=endpoint**, enter the endpoint that you copied in the preceding steps.
 - For **PORT=portnum**, enter the port number that you copied in the preceding steps.
 - For **SID=DB_NAME**, enter the Oracle database name (not the instance name) that you copied in the preceding steps.

```
sqlplus 'dbuser@(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=endpoint)(PORT=portnum))(CONNECT_DATA=(SID=DB_NAME)))'
```

You should see output similar to the following.

```
SQL*Plus: Release 11.1.0.7.0 - Production on Wed May 25 15:13:59 2011
SQL>
```

For more information about connecting to an Oracle DB instance, see [Connecting to your Oracle DB instance \(p. 1001\)](#). For information on connection issues, see [Can't connect to Amazon RDS DB instance \(p. 1746\)](#).

Deleting your sample DB instance

After you are done exploring the sample DB instance that you created, you should delete the DB instance so that you are no longer charged for it.

To delete a DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to delete.
4. For **Actions**, choose **Delete**.
5. For **Create final snapshot?**, choose **No**, and choose the acknowledgment.
6. Choose **Delete**.

Creating a PostgreSQL DB instance and connecting to a database on a PostgreSQL DB instance

The easiest way to create a DB instance is to use the RDS console. After you have created the DB instance, you can use standard SQL client utilities to connect to the DB instance, such as the pgAdmin utility. In this example, you create a DB instance running the PostgreSQL database engine called database-1, with a db.t2.micro DB instance class and 20 gibibytes (GiB) of storage.

Important

Before you can create or connect to a DB instance, you must complete the tasks in [Setting up for Amazon RDS \(p. 67\)](#).

Contents

- [Creating a PostgreSQL DB instance \(p. 99\)](#)
- [Connecting to a PostgreSQL DB instance \(p. 103\)](#)
 - [Using pgAdmin to connect to a PostgreSQL DB instance \(p. 103\)](#)
 - [Using psql to connect to a PostgreSQL DB instance \(p. 107\)](#)
- [Deleting a DB instance \(p. 107\)](#)

Creating a PostgreSQL DB instance

The basic building block of Amazon RDS is the DB instance. This environment is where you run your PostgreSQL databases.

You can create a DB instance running PostgreSQL with the AWS Management Console with **Easy Create** enabled or disabled. With **Easy Create** enabled, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy Create** uses the default setting for other configuration options. With **Easy Create** not enabled, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

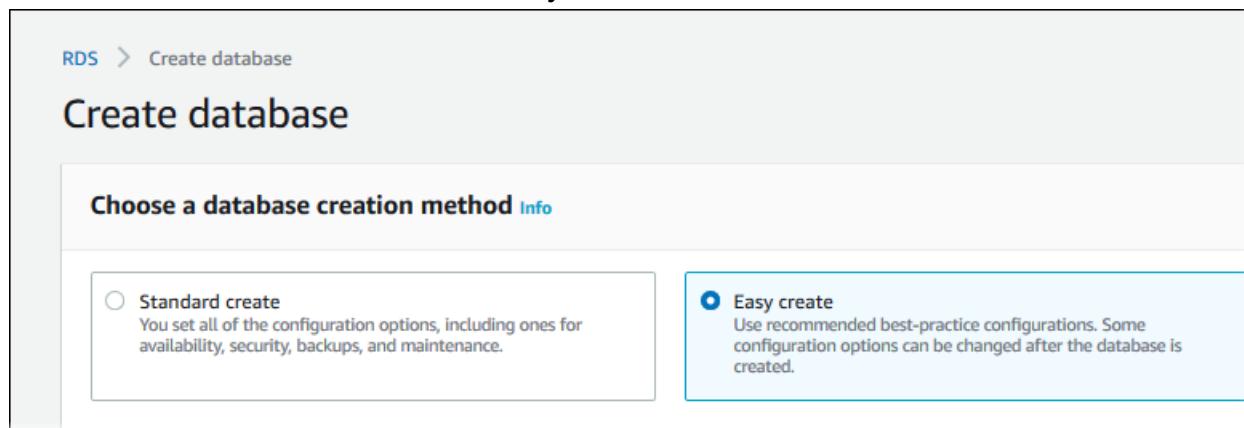

In this example, you use **Easy Create** to create a DB instance running the PostgreSQL database engine with a db.t2.micro DB instance class.

Note

For information about creating DB instances with **Easy Create** not enabled, see [Creating an Amazon RDS DB instance \(p. 141\)](#).

To create a PostgreSQL DB instance with Easy Create enabled

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database** and make sure that **Easy Create** is chosen.

5. In **Configuration**, choose **PostgreSQL**.
6. For **DB instance size**, choose **Free tier**.
7. For **DB instance identifier**, enter a name for the DB instance, or leave the default name.
8. For **Master username**, enter a name for the master user, or leave the default name.

The **Create database** page should look similar to the following image.

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1–63 characters or backticks (1 to 15 for SQL Server). First character must be a letter. Can't contain two consecutive hyphens.

- To use an automatically generated master password for the DB instance, make sure that the **Auto generate a password** check box is chosen.

To enter your master password, clear the **Auto generate a password** check box, and then enter the same password in **Master password** and **Confirm password**.

- (Optional) Open **View default settings for Easy create**.

View default settings for Easy create

Easy create sets the following configurations to their default values, some of which can be changed later. If you want to change any of these settings now, use [Standard Create](#).

Configuration	Value	Editable after database is created
Encryption	Enabled	No
VPC	Default VPC (vpc-1234567a)	No
Option Group	default:oracle-se2-19	Yes
Subnet Group	default-vpc-1234567a	Yes
Automatic Backups	Enabled	Yes
VPC Security Group	sg-1a2bcd3e	Yes
Publicly Accessible	No	Yes
Database Port	1521	Yes

You can examine the default settings used when **Easy Create** is enabled. If you want to change one or more settings during database creation, choose **Standard Create** to set them. The **Editable after database creation** column shows which options you can change after database creation. To change a setting with **No** in that column, use **Standard Create**. For settings with **Yes** in that column, you can either use **Standard Create** or modify the DB instance after it's created to change the setting.

- Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB instance, choose **View credential details**.

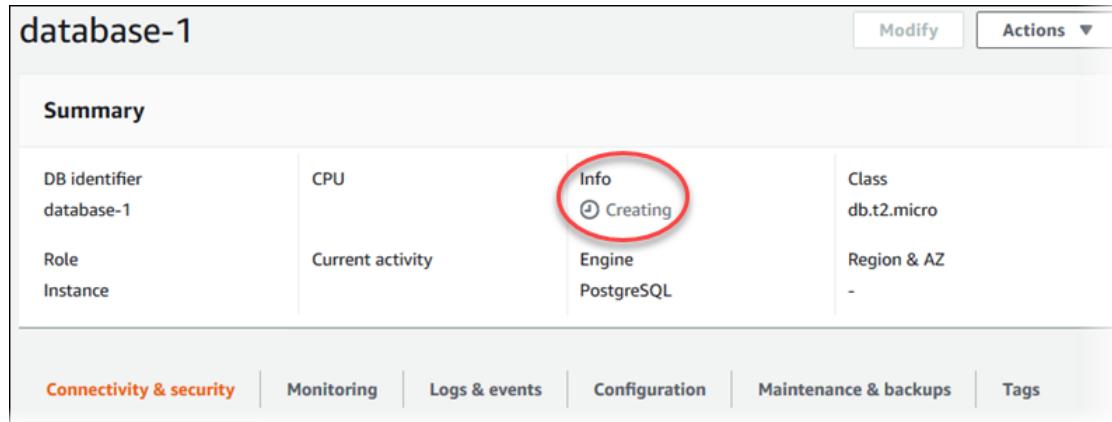

To connect to the DB instance as the master user, use the user name and password that appear.

Important

You can't view the master user password again. If you don't record it, you might have to change it. If you need to change the master user password after the DB instance is available, you can modify the DB instance to do so. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

- For **Databases**, choose the name of the new PostgreSQL DB instance.

On the RDS console, the details for new DB instance appear. The DB instance has a status of **creating** until the DB instance is ready to use. When the state changes to **available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

Connecting to a PostgreSQL DB instance

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the instance. The security group that you assigned to the DB instance when you created it must allow access to the DB instance. If you have difficulty connecting to the DB instance, the problem is most often with the access rules you set up in the security group you assigned to the DB instance.

This section shows two ways to connect to a PostgreSQL DB instance. The first example uses pgAdmin, a popular open-source administration and development tool for PostgreSQL. You can download and use pgAdmin without having a local instance of PostgreSQL on your client computer. The second example uses psql, a command line utility that is part of a PostgreSQL installation. To use psql, you must have a PostgreSQL installed on your client computer or have installed the psql client on your machine.

For more information about connecting to a PostgreSQL DB instance, see [Connecting to a DB instance running the PostgreSQL database engine \(p. 1508\)](#). If you can't connect to your DB instance, see [Troubleshooting connections to your PostgreSQL instance \(p. 1511\)](#).

Topics

- [Using pgAdmin to connect to a PostgreSQL DB instance \(p. 103\)](#)
- [Using psql to connect to a PostgreSQL DB instance \(p. 107\)](#)

Using pgAdmin to connect to a PostgreSQL DB instance

To connect to a PostgreSQL DB instance using pgAdmin

1. Find the endpoint (DNS name) and port number for your DB instance.
 - a. Open the RDS console and then choose **Databases** to display a list of your DB instances.
 - b. Choose the PostgreSQL DB instance name to display its details.
 - c. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

database-1

Summary

DB identifier
database-1

Role
Instance

Connectivity & security Monitoring Logs & events

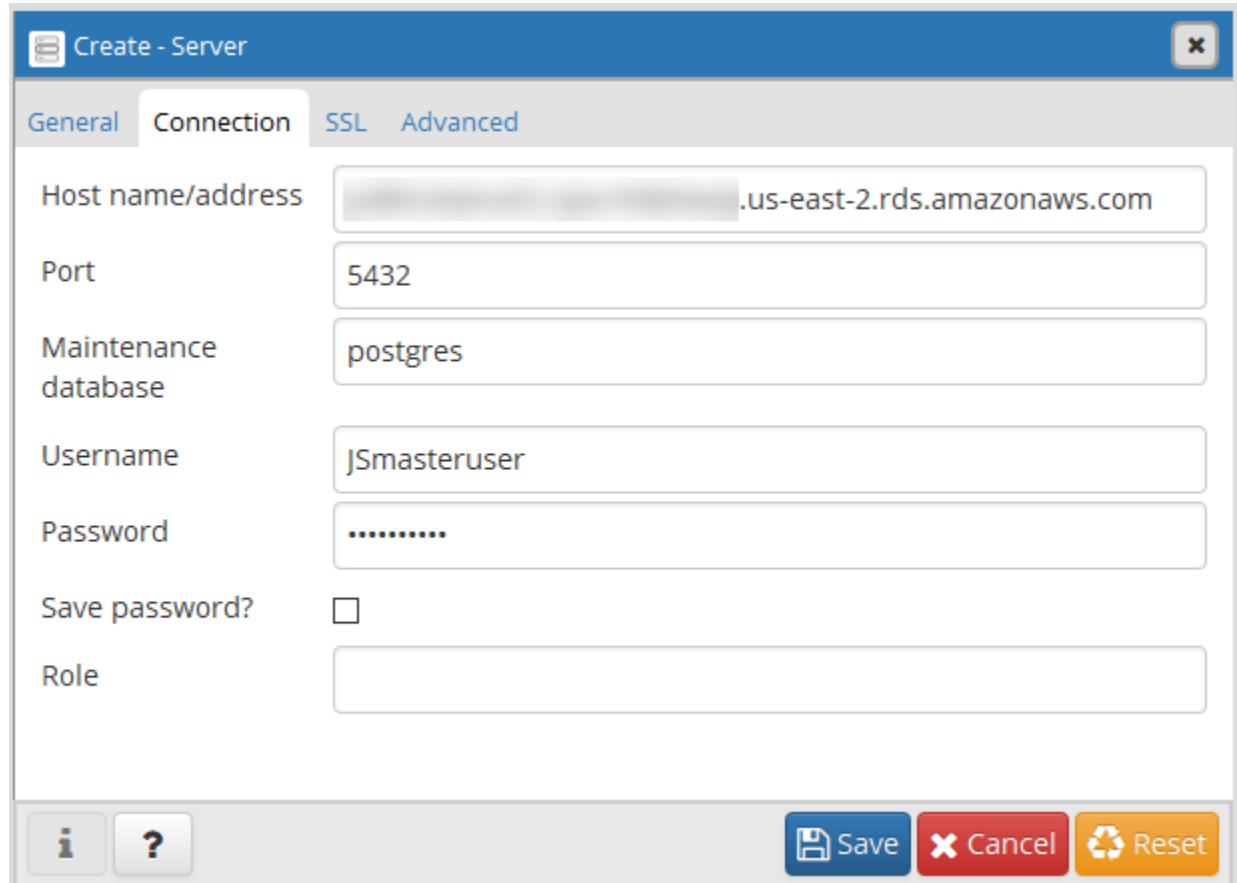

Connectivity & security

Endpoint
database-1.c6c8dntfzzhgv0.us-west-1.rds.amazonaws.com

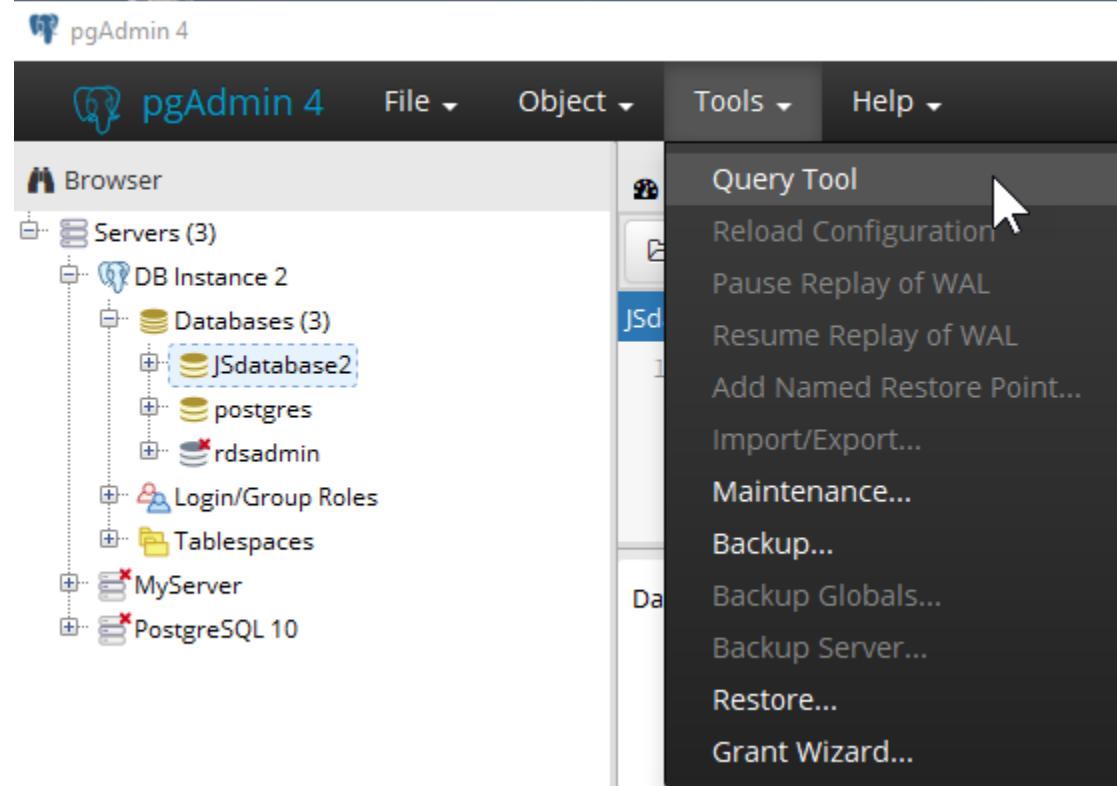

Port
5432

2. Install pgAdmin from <https://www.pgadmin.org/>. You can download and use pgAdmin without having a local instance of PostgreSQL on your client computer.
3. Launch the pgAdmin application on your client computer.
4. Choose **Add Server** from the **File** menu.
5. In the **New Server Registration** dialog box, enter the DB instance endpoint (for example, `database-1.c6c8dntfzzhgv0.us-west-1.rds.amazonaws.com`) in the **Host** box. Don't include the colon or port number as shown on the Amazon RDS console (`database-1.c6c8dntfzzhgv0.us-west-1.rds.amazonaws.com:5432`).

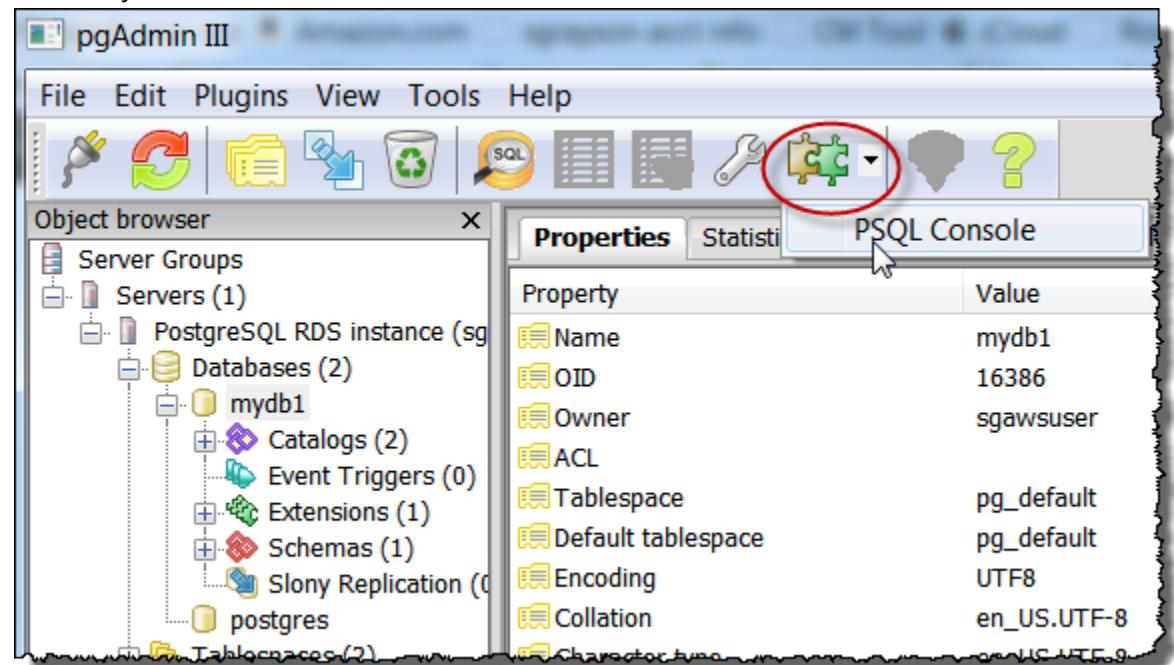

Enter the port you assigned to the DB instance for **Port**. Enter the user name and user password that you entered when you created the DB instance for **Username** and **Password**.

6. Choose **OK**.
7. In the Object browser, expand **Server Groups**. Choose the server (the DB instance) you created, and then choose the database name.

8. Choose the plugin icon and choose **PSQL Console**. The psql command window opens for the default database you created.

9. Use the command window to enter SQL or psql commands. Enter \q to close the window.

Using psql to connect to a PostgreSQL DB instance

If your client computer has PostgreSQL installed, you can use a local instance of psql to connect to a PostgreSQL DB instance. To connect to your PostgreSQL DB instance using psql, provide host information and access credentials.

The following format is used to connect to a PostgreSQL DB instance on Amazon RDS.

```
psql --host=DB_instance_endpoint --port=port --username=master_user_name --password --  
dbname=database_name
```

For example, the following command connects to a database called mypgdb on a PostgreSQL DB instance called mypostgresql using fictitious credentials.

```
psql --host=database-1.c6c8dntfzzhgv0.us-west-1.rds.amazonaws.com --port=5432 --  
username=awsuser --password --dbname=postgres
```

Deleting a DB instance

After you have connected to the sample DB instance that you created, you should delete the DB instance so you are no longer charged for it.

To delete a DB instance with no final DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to delete.
4. For **Actions**, choose **Delete**.
5. For **Create final snapshot?**, choose **No**, and select the acknowledgment.
6. Choose **Delete**.

Tutorial: Create a web server and an Amazon RDS DB instance

This tutorial helps you install an Apache web server with PHP and create a MySQL database. The web server runs on an Amazon EC2 instance using Amazon Linux, and the MySQL database is an MySQL DB instance. Both the Amazon EC2 instance and the DB instance run in a virtual private cloud (VPC) based on the Amazon VPC service.

Important

There's no charge for creating an AWS account. However, by completing this tutorial, you might incur costs for the AWS resources you use. You can delete these resources after you complete the tutorial if they are no longer needed.

Note

This tutorial works with Amazon Linux and might not work for other versions of Linux such as Ubuntu.

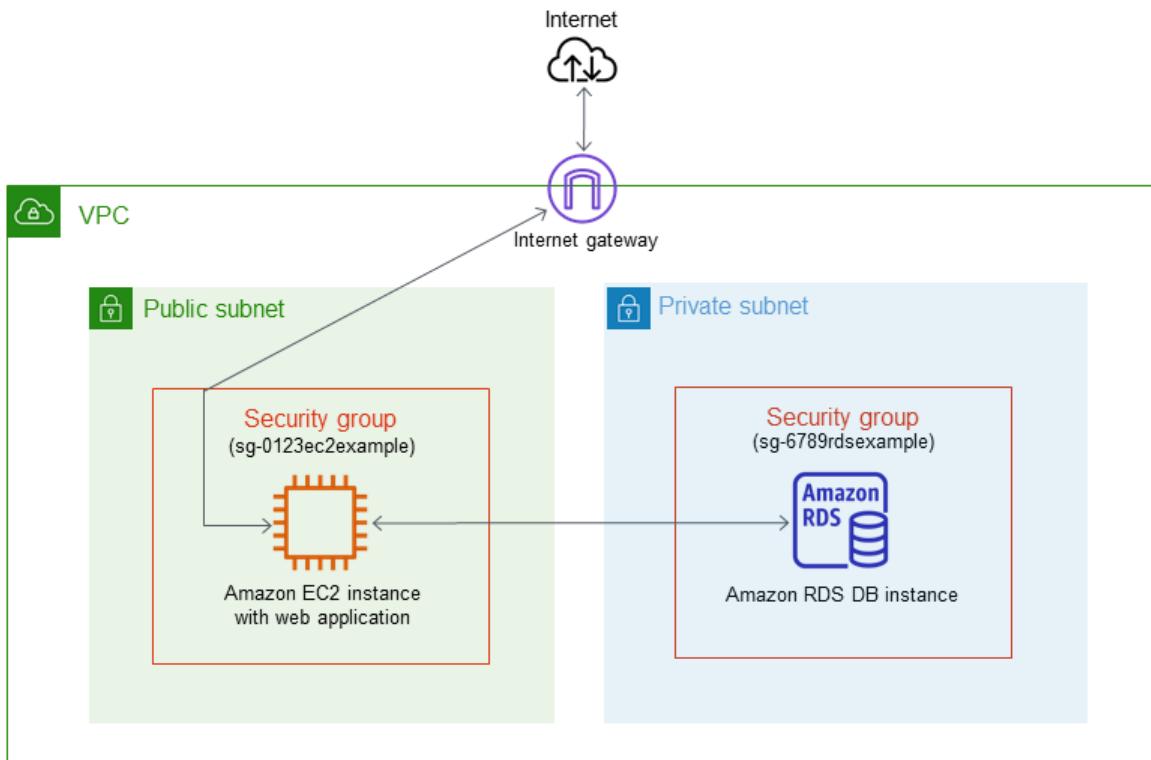

In the tutorial that follows, you specify the VPC, subnets, and security groups when you create the DB instance. You also specify them when you create the EC2 instance to host your web server. The VPC, subnets, and security groups are required for the DB instance and the web server to communicate. After the VPC is set up, this tutorial shows you how to create the DB instance and install the web server. You connect your web server to your DB instance in the VPC using the DB instance endpoint endpoint.

1. Complete the tasks in [Tutorial: Create an Amazon VPC for use with a DB instance \(p. 1737\)](#).

Before you begin this tutorial, make sure that you have a VPC with both public and private subnets, and corresponding security groups. If you don't have these, complete the following tasks in the tutorial:

- a. [Create a VPC with private and public subnets \(p. 1737\)](#)
 - b. [Create additional subnets \(p. 1738\)](#)
 - c. [Create a VPC security group for a public web server \(p. 1739\)](#)
 - d. [Create a VPC security group for a private DB instance \(p. 1740\)](#)
 - e. [Create a DB subnet group \(p. 1740\)](#)
2. [Create a DB instance \(p. 109\)](#)
 3. [Create an EC2 instance and install a web server \(p. 114\)](#)

The following diagram shows the configuration when the tutorial is complete.

Create a DB instance

In this step, you create an Amazon RDS for MySQL DB instance that maintains the data used by a web application.

Important

Before you begin this step, make sure that you have a VPC with both public and private subnets, and corresponding security groups. If you don't have these, see [Tutorial: Create an Amazon VPC for use with a DB instance \(p. 1737\)](#). Complete the steps in [Create a VPC with private and public subnets \(p. 1737\)](#), [Create additional subnets \(p. 1738\)](#), [Create a VPC security group for a public web server \(p. 1739\)](#), and [Create a VPC security group for a private DB instance \(p. 1740\)](#).

To create a MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region where you want to create the DB instance. This example uses the US West (Oregon) Region.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. On the **Create database** page, shown following, make sure that the **Standard create** option is chosen, and then choose **MySQL**.

RDS > Create database

Create database

Choose a database creation method [Info](#)

Standard create
You set all of the configuration options, including ones for availability, security, backups, and maintenance.

Easy create
Use recommended best-practice configurations. Some configuration options can be changed after the database is created.

Engine options

Engine type [Info](#)

Amazon Aurora

MySQL

MariaDB

PostgreSQL

Oracle

Microsoft SQL Server

Edition

MySQL Community

Known issues/limitations
Review the [Known issues/limitations](#) to learn about potential compatibility issues with specific database versions.

Version

6. In the **Templates** section, choose **Free tier**.
7. In the **Settings** section, set these values:
 - **DB instance identifier** – `tutorial-db-instance`
 - **Master username** – `tutorial_user`
 - **Auto generate a password** – Disable the option.
 - **Master password** – Choose a password.
 - **Confirm password** – Retype the password.

Settings

DB instance identifier [Info](#)
Type a name for your DB instance. The name must be unique cross all DB instances owned by your AWS account in the current AWS Region.

tutorial-db-instance

The DB instance identifier is case-insensitive, but is stored as all lowercase (as in "mydbinstance"). Constraints: 1 to 60 alphanumeric characters or hyphens (1 to 15 for SQL Server). First character must be a letter. Can't contain two consecutive hyphens. Can't end with a hyphen.

Credentials Settings

Master username [Info](#)
Type a login ID for the master user of your DB instance.

tutorial_user

1 to 16 alphanumeric characters. First character must be a letter

Auto generate a password
Amazon RDS can generate a password for you, or you can specify your own password

Master password [Info](#)

Constraints: At least 8 printable ASCII characters. Can't contain any of the following: / (slash), " (double quote) and @ (at sign).

Confirm password [Info](#)

8. In the **DB instance class** section, enable **Include previous generation classes**, and set these values:
 - **Burstable classes (includes t classes)**
 - **db.t2.micro**

DB instance class

DB instance class [Info](#)
Choose a DB instance class that meets your processing power and memory requirements. The DB instance class options below are limited to those supported by the engine you selected above.

Standard classes (includes m classes)
 Memory optimized classes (includes r and x classes)
 Burstable classes (includes t classes)

db.t2.small
1 vCPUs 2 GiB RAM Not EBS Optimized

New instance classes are available for specific engine versions. [Info](#)

Include previous generation classes

9. In the **Storage and Availability & durability** sections, use the default values.
 10. In the **Connectivity** section, set these values:
 - **Virtual private cloud (VPC)** – Choose an existing VPC with both public and private subnets, such as the tutorial-vpc (vpc-*identifier*) created in [Create a VPC with private and public subnets \(p. 1737\)](#)
- Note**
The VPC must have subnets in different Availability Zones.
- **Subnet group** – The DB subnet group for the VPC, such as the tutorial-db-subnet-group created in [Create a DB subnet group \(p. 1740\)](#)
 - **Public access** – No
 - **VPC security group** – Choose existing
 - **Existing VPC security groups** – Choose an existing VPC security group that is configured for private access, such as the tutorial-db-securitygroup created in [Create a VPC security group for a private DB instance \(p. 1740\)](#).

Remove other security groups, such as the default security group, by choosing the **X** associated with each.

- **Availability Zone** – No preference
- Open **Additional configuration**, and make sure **Database port** uses the default value **3306**.

Connectivity

Virtual private cloud (VPC) [Info](#)
VPC that defines the virtual networking environment for this DB instance.

tutorial-vpc (vpc-08bf0876fa2e229cf)

Only VPCs with a corresponding DB subnet group are listed.

Subnet group [Info](#)
DB subnet group that defines which subnets and IP ranges the DB instance can use in the VPC you selected.

tutorial-db-subnet-group

Public access [Info](#)

Yes
Amazon EC2 instances and devices outside the VPC can connect to your database. Choose one or more VPC security groups that specify which EC2 instances and devices inside the VPC can connect to the database.

No
RDS will not assign a public IP address to the database. Only Amazon EC2 instances and devices inside the VPC can connect to your database.

VPC security group
Choose a VPC security group to allow access to your database. Ensure that the security group rules allow the appropriate incoming traffic.

Choose existing
Choose existing VPC security groups

Create new
Create new VPC security group

Existing VPC security groups

Choose VPC security groups

tutorial-db-securitygroup X

Availability Zone [Info](#)

No preference

▼ Additional configuration

Database port [Info](#)
TCP/IP port that the database will use for application connections.

3306

11. In the **Database authentication** section, make sure **Password authentication** is selected.
 12. Open the **Additional configuration** section, and enter **sample** for **Initial database name**. Keep the default settings for the other options.
 13. To create your MySQL DB instance, choose **Create database**.
- Your new DB instance appears in the **Databases** list with the status **Creating**.
14. Wait for the **Status** of your new DB instance to show as **Available**. Then choose the DB instance name to show its details.
 15. In the **Connectivity & security** section, view the **Endpoint** and **Port** of the DB instance.

tutorial-db-instance

Summary

DB identifier	CPU
tutorial-db-instance	
Role	Current activity
Instance	0 Connections

Connectivity & security

Endpoint & port	Network
Endpoint	Availability
tutorial-db-instance. [REDACTED].us-west-2.rds.amazonaws.com	us-west-
Port	VPC
3306	tutorial-
	Subnet [REDACTED]

Note the endpoint and port for your DB instance. You use this information to connect your web server to your DB instance.

16. Complete [Create an EC2 instance and install a web server \(p. 114\)](#).

Create an EC2 instance and install a web server

In this step, you create a web server to connect to the Amazon RDS DB instance that you created in [Create a DB instance \(p. 109\)](#).

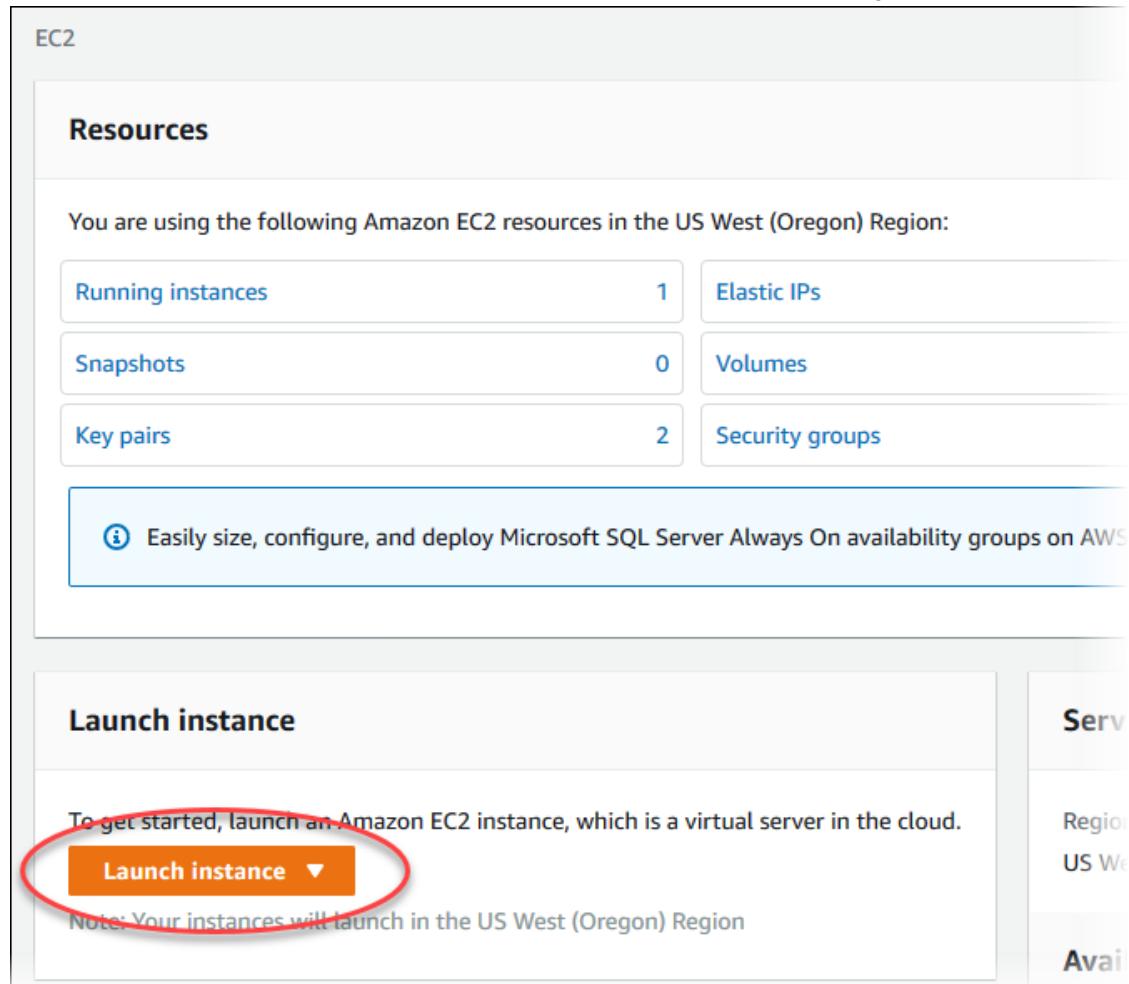

Launch an EC2 instance

First, you create an Amazon EC2 instance in the public subnet of your VPC.

114

To launch an EC2 instance

1. Sign in to the AWS Management Console and open the Amazon EC2 console at <https://console.aws.amazon.com/ec2/>.
2. Choose **EC2 Dashboard**, and then choose **Launch instance**, as shown following.

3. Choose the **Amazon Linux 2 AMI**.

Step 1: Choose an Amazon Machine Image (AMI)

An AMI is a template that contains the software configuration (operating system, application server, and applications) required to launch your instance. You can select an AMI provided by AWS, our user community, or the AWS Marketplace; or you can select one of your own AMIs.

Search for an AMI by entering a search term e.g. "Windows"

Cancel and Exit

Quick Start

My AMIs

AWS Marketplace

Community AMIs

Free tier only ⓘ

Amazon Linux 2 AMI (HVM), SSD Volume Type - ami-07a0da1997b55b23e (64-bit x86) / ami-0787fda5708b00aa3 (64-bit Arm)

Amazon Linux 2 comes with five years support. It provides Linux kernel 4.14 tuned for optimal performance on Amazon EC2, systemd 219, GCC 7.3, Glibc 2.26, Binutils 2.29.1, and the latest software packages through extras. This AMI is the successor of the Amazon Linux AMI that is approaching end of life on December 31, 2020 and has been removed from this wizard.

Root device type: ebs Virtualization type: hvm ENA Enabled: Yes

Select

Red Hat Enterprise Linux 8 (HVM), SSD Volume Type - ami-01e78c5619c5e68b4 (64-bit x86) / ami-0a1158e1a81fe09a (64-bit Arm)

Red Hat Enterprise Linux version 8 (HVM), EBS General Purpose (SSD) Volume Type

Root device type: ebs Virtualization type: hvm ENA Enabled: Yes

Select

SUSE Linux Enterprise Server 15 SP2 (HVM), SSD Volume Type - ami-063c2d222d223d0e9 (64-bit x86) / ami-0bfc92b18fd79372c (64-bit Arm)

Select

4. Choose the **t2.micro** instance type, as shown following, and then choose **Next: Configure Instance Details**.

Step 2: Choose an Instance Type

Amazon EC2 provides a wide selection of instance types optimized to fit different use cases. Instances are virtual servers that can run applications. They have varying combinations of CPU, memory, storage, and networking capacity, and give you the flexibility to choose the appropriate mix of resources for your applications. [Learn more](#) about instance types and how they can meet your computing needs.

Filter by: All instance families Current generation Show/Hide Columns

Currently selected: t2.micro (- ECUs, 1 vCPUs, 2.5 GHz, -, 1 GiB memory, EBS only)

Family	Type	vCPUs ⓘ	Memory (GiB)	Instance Storage (GB) ⓘ	EBS-Optimized Available ⓘ	Network Performance ⓘ	IPv6 Support ⓘ
t2	t2.nano	1	0.5	EBS only	-	Low to Moderate	Yes
t2	t2.micro Free tier eligible	1	1	EBS only	-	Low to Moderate	Yes
t2	t2.small	1	2	EBS only	-	Low to Moderate	Yes
t2	t2.medium	2	4	EBS only	-	Low to Moderate	Yes
t2	t2.large	2	8	EBS only	-	Low to Moderate	Yes

Cancel Previous Review and Launch Next: Configure Instance Details

5. On the **Configure Instance Details** page, shown following, set these values and keep the other values as their defaults:

- Network:** Choose the VPC with both public and private subnets that you chose for the DB instance, such as the `vpc-identifier | tutorial-vpc` created in [Create a VPC with private and public subnets \(p. 1737\)](#).
- Subnet:** Choose an existing public subnet, such as `subnet-identifier | Tutorial public | us-west-2a` created in [Create a VPC security group for a public web server \(p. 1739\)](#).
- Auto-assign Public IP:** Choose **Enable**.

Step 3: Configure Instance Details

Configure the instance to suit your requirements. You can launch multiple instances from the same AMI, request Spot instances to take advantage of the lower pricing, assign an access management role to the instance, and more.

Number of Instances <input type="text" value="1"/>	<input type="checkbox"/> Launch into Auto Scaling Group
Purchasing option <input type="checkbox"/> Request Spot instances	
Network <input type="text" value="vpc"/> tutorial-vpc <input type="button" value="Create new VPC"/> Subnet <input type="text" value="subnet-000000000000000000"/> Tutorial public us-east-1 <input type="button" value="Create new subnet"/> 249 IP Addresses available Auto-assign Public IP <input checked="" type="checkbox"/> Enable	
Placement group <input type="checkbox"/> Add instance to placement group Capacity Reservation <input type="button" value="Open"/> Domain join directory <input type="text" value="No directory"/> <input type="button" value="Create new directory"/> IAM role <input type="text" value="None"/> <input type="button" value="Create new IAM role"/>	
CPU options <input type="checkbox"/> Specify CPU options	
Shutdown behavior <input type="button" value="Stop"/> Stop - Hibernate behavior <input type="checkbox"/> Enable hibernation as an additional stop behavior Enable termination protection <input type="checkbox"/> Protect against accidental termination Monitoring <input type="checkbox"/> Enable CloudWatch detailed monitoring <small>Additional charges apply.</small> Tenancy <input type="button" value="Shared - Run a shared hardware instance"/> <small>Additional charges will apply for dedicated tenancy.</small> Elastic Inference <input type="checkbox"/> Add an Elastic Inference accelerator	
<input type="button" value="Cancel"/> <input type="button" value="Previous"/> <input style="background-color: #0070C0; color: white; font-weight: bold; border-radius: 5px; border: none; padding: 2px 10px;" type="button" value="Review and Launch"/> <input type="button" value="Next: Add Storage"/>	

6. Choose **Next: Add Storage**.
7. On the **Add Storage** page, keep the default values and choose **Next: Add Tags**.
8. On the **Add Tags** page, shown following, choose **Add Tag**, then enter **Name** for **Key** and enter **tutorial-web-server** for **Value**.

Step 5: Add Tags

A tag consists of a case-sensitive key-value pair. For example, you could define a tag with key = Name and value = Webserver. A copy of a tag can be applied to volumes, instances or both. Tags will be applied to all instances and volumes. [Learn more](#) about tagging your Amazon EC2 resources.

Key (127 characters maximum)	Value (255 characters maximum)	Instances <input type="checkbox"/>	Volumes <input type="checkbox"/>
<input type="text" value="Name"/>	<input type="text" value="tutorial-web-server"/>	<input type="checkbox"/>	<input type="checkbox"/>
<input type="button" value="Add another tag"/> (Up to 50 tags maximum)			
<input type="button" value="Cancel"/> <input type="button" value="Previous"/> <input style="background-color: #0070C0; color: white; font-weight: bold; border-radius: 5px; border: none; padding: 2px 10px;" type="button" value="Review and Launch"/> <input type="button" value="Next: Configure Security Group"/>			

9. Choose **Next: Configure Security Group**.
10. On the **Configure Security Group** page, shown following, choose **Select an existing security group**. Then choose an existing security group, such as the **tutorial-securitygroup** created in [Create a VPC security group for a public web server \(p. 1739\)](#). Make sure that the security group that you choose includes inbound rules for Secure Shell (SSH) and HTTP access.

Step 6: Configure Security Group

A security group is a set of firewall rules that control the traffic for your instance. On this page, you can add rules to allow specific traffic to reach your instance. For example, if you want to set up a web server and allow Internet traffic to reach your instance, add rules that allow unrestricted access to the HTTP and HTTPS ports. You can create a new security group or select from an existing one below. [Learn more](#) about Amazon EC2 security groups.

Assign a security group: Create a new security group
 Select an existing security group

Security Group ID	Name	Description	Actions
<input type="checkbox"/> sg-[REDACTED]	default	default VPC security group	Copy to new
<input type="checkbox"/> sg-[REDACTED]	tutorial-db-securitygroup	Tutorial DB Instance Security Group	Copy to new

13. On the **Select an existing key pair or create a new key pair** page, shown following, choose **Create a new key pair** and set **Key pair name** to **tutorial-key-pair**. Choose **Download Key Pair**, and then save the key pair file on your local machine. You use this key pair file to connect to your EC2 instance.

14. To launch your EC2 instance, choose **Launch Instances**. On the **Launch Status** page, shown following, note the identifier for your new EC2 instance, for example: i-0288d65fd4470b6a9.

Launch Status

Your instances are now launching
The following instance launches have been initiated: [i-0288d65fd4470b6a9](#) [View launch log](#)

Get notified of estimated charges
Create [billing alerts](#) to get an email notification when estimated charges on your AWS bill exceed an amount you define (for example, if you exceed the free usage tier).

How to connect to your instances

Your instances are launching, and it may take a few minutes until they are in the **running** state, when they will be ready for you to use. Usage hours on your new instances will start immediately and continue to accrue until you stop or terminate your instances.

Click [View Instances](#) to monitor your instances' status. Once your instances are in the **running** state, you can [connect](#) to them from the Instances screen. [Find out](#) how to connect to your instances.

▼ Here are some helpful resources to get you started

- [How to connect to your Linux instance](#)
- [Learn about AWS Free Usage Tier](#)
- [Amazon EC2: User Guide](#)
- [Amazon EC2: Discussion Forum](#)

While your instances are launching you can also

- [Create status check alarms](#) to be notified when these instances fail status checks. (Additional charges may apply)
- [Create and attach additional EBS volumes](#) (Additional charges may apply)
- [Manage security groups](#)

[View Instances](#)

15. Choose [View Instances](#) to find your instance.
16. Wait until **Instance Status** for your instance reads as **Running** before continuing.

Install an Apache web server with PHP

Next, you connect to your EC2 instance and install the web server.

To connect to your EC2 instance and install the Apache web server with PHP

1. Connect to the EC2 instance that you created earlier by following the steps in [Connect to your Linux instance](#).
2. Get the latest bug fixes and security updates by updating the software on your EC2 instance. To do this, use the following command.

Note

The `-y` option installs the updates without asking for confirmation. To examine updates before installing, omit this option.

```
sudo yum update -y
```

3. After the updates complete, install the PHP software using the `amazon-linux-extras install` command. This command installs multiple software packages and related dependencies at the same time.

```
sudo amazon-linux-extras install -y lamp-mariadb10.2-php7.2 php7.2
```

If you receive an error stating `sudo: amazon-linux-extras: command not found`, then your instance was not launched with an Amazon Linux 2 AMI (perhaps you are using the Amazon Linux AMI instead). You can view your version of Amazon Linux using the following command.

```
cat /etc/system-release
```

For more information, see [Updating instance software](#).

4. Install the Apache web server.

```
sudo yum install -y httpd
```

5. Start the web server with the command shown following.

```
sudo systemctl start httpd
```

You can test that your web server is properly installed and started. To do this, enter the public Domain Name System (DNS) name of your EC2 instance in the address bar of a web browser, for example: `http://ec2-42-8-168-21.us-west-1.compute.amazonaws.com`. If your web server is running, then you see the Apache test page.

If you don't see the Apache test page, check your inbound rules for the VPC security group that you created in [Tutorial: Create an Amazon VPC for use with a DB instance \(p. 1737\)](#). Make sure that your inbound rules include a rule allowing HTTP (port 80) access for the IP address you use to connect to the web server.

Note

The Apache test page appears only when there is no content in the document root directory, `/var/www/html`. After you add content to the document root directory, your content appears at the public DNS address of your EC2 instance instead of the Apache test page.

6. Configure the web server to start with each system boot using the `systemctl` command.

```
sudo systemctl enable httpd
```

To allow `ec2-user` to manage files in the default root directory for your Apache web server, modify the ownership and permissions of the `/var/www` directory. There are many ways to accomplish this task. In this tutorial, you add `ec2-user` to the `apache` group, to give the `apache` group ownership of the `/var/www` directory and assign write permissions to the group.

To set file permissions for the Apache web server

1. Add the `ec2-user` user to the `apache` group.

```
sudo usermod -a -G apache ec2-user
```

2. Log out to refresh your permissions and include the new `apache` group.

```
exit
```

3. Log back in again and verify that the `apache` group exists with the `groups` command.

```
groups
```

Your output looks similar to the following:

```
ec2-user adm wheel apache systemd-journal
```

4. Change the group ownership of the /var/www directory and its contents to the apache group.

```
sudo chown -R ec2-user:apache /var/www
```

5. Change the directory permissions of /var/www and its subdirectories to add group write permissions and set the group ID on subdirectories created in the future.

```
sudo chmod 2775 /var/www
find /var/www -type d -exec sudo chmod 2775 {} \;
```

6. Recursively change the permissions for files in the /var/www directory and its subdirectories to add group write permissions.

```
find /var/www -type f -exec sudo chmod 0664 {} \;
```

Now, `ec2-user` (and any future members of the `apache` group) can add, delete, and edit files in the Apache document root, enabling you to add content, such as a static website or a PHP application.

Note

A web server running the HTTP protocol provides no transport security for the data that it sends or receives. When you connect to an HTTP server using a web browser, the URLs that you visit, the content of web pages that you receive, and the contents (including passwords) of any HTML forms that you submit are all visible to eavesdroppers anywhere along the network pathway. The best practice for securing your web server is to install support for HTTPS (HTTP Secure), which protects your data with SSL/TLS encryption. For more information, see [Tutorial: Configure SSL/TLS with the Amazon Linux AMI](#) in the *Amazon EC2 User Guide*.

Connect your Apache web server to your DB instance

Next, you add content to your Apache web server that connects to your Amazon RDS DB instance.

To add content to the Apache web server that connects to your DB instance

1. While still connected to your EC2 instance, change the directory to /var/www and create a new subdirectory named `inc`.

```
cd /var/www
mkdir inc
cd inc
```

2. Create a new file in the `inc` directory named `dbinfo.inc`, and then edit the file by calling nano (or the editor of your choice).

```
>dbinfo.inc
nano dbinfo.inc
```

3. Add the following contents to the `dbinfo.inc` file. Here, `db_instance_endpoint` is your DB instance endpoint, without the port, and `master_password` is the master password for your DB instance.

Note

We recommend placing the user name and password information in a folder that isn't part of the document root for your web server. Doing this reduces the possibility of your security information being exposed.

```
<?php

define('DB_SERVER', 'db_instance_endpoint');
define('DB_USERNAME', 'tutorial_user');
define('DB_PASSWORD', 'master password');
define('DB_DATABASE', 'sample');

?>
```

4. Save and close the dbinfo.inc file.
5. Change the directory to /var/www/html.

```
cd /var/www/html
```

6. Create a new file in the html directory named SamplePage.php, and then edit the file by calling nano (or the editor of your choice).

```
>SamplePage.php
nano SamplePage.php
```

7. Add the following contents to the SamplePage.php file:

Note

We recommend placing the user name and password information in a folder that isn't part of the document root for your web server. Doing this reduces the possibility of your security information being exposed.

```
<?php include "../inc/dbinfo.inc"; ?>
<html>
<body>
<h1>Sample page</h1>
<?php

/* Connect to MySQL and select the database. */
$connection = mysqli_connect(DB_SERVER, DB_USERNAME, DB_PASSWORD);

if (mysqli_connect_errno()) echo "Failed to connect to MySQL: " .
mysqli_connect_error();

$database = mysqli_select_db($connection, DB_DATABASE);

/* Ensure that the EMPLOYEES table exists. */
VerifyEmployeesTable($connection, DB_DATABASE);

/* If input fields are populated, add a row to the EMPLOYEES table. */
$employee_name = htmlentities($_POST['NAME']);
$employee_address = htmlentities($_POST['ADDRESS']);

if (strlen($employee_name) || strlen($employee_address)) {
    AddEmployee($connection, $employee_name, $employee_address);
}
?>
```

```

<!-- Input form -->
<form action="<?PHP echo $_SERVER['SCRIPT_NAME'] ?>" method="POST">
  <table border="0">
    <tr>
      <td>NAME</td>
      <td>ADDRESS</td>
    </tr>
    <tr>
      <td>
        <input type="text" name="NAME" maxlength="45" size="30" />
      </td>
      <td>
        <input type="text" name="ADDRESS" maxlength="90" size="60" />
      </td>
      <td>
        <input type="submit" value="Add Data" />
      </td>
    </tr>
  </table>
</form>

<!-- Display table data. -->
<table border="1" cellpadding="2" cellspacing="2">
  <tr>
    <td>ID</td>
    <td>NAME</td>
    <td>ADDRESS</td>
  </tr>
<?php

$result = mysqli_query($connection, "SELECT * FROM EMPLOYEES");

while($query_data = mysqli_fetch_row($result)) {
  echo "<tr>";
  echo "<td>",$query_data[0], "</td>",
        "<td>",$query_data[1], "</td>",
        "<td>",$query_data[2], "</td>";
  echo "</tr>";
}
?>

</table>

<!-- Clean up. -->
<?php

mysqli_free_result($result);
mysqli_close($connection);

?>

</body>
</html>

<?php

/* Add an employee to the table. */
function AddEmployee($connection, $name, $address) {
  $n = mysqli_real_escape_string($connection, $name);
  $a = mysqli_real_escape_string($connection, $address);

  $query = "INSERT INTO EMPLOYEES (NAME, ADDRESS) VALUES ('$n', '$a');";

  if(!mysqli_query($connection, $query)) echo("<p>Error adding employee data.</p>");
```

```
}

/* Check whether the table exists and, if not, create it. */
function VerifyEmployeesTable($connection, $dbName) {
    if(!TableExists("EMPLOYEES", $connection, $dbName))
    {
        $query = "CREATE TABLE EMPLOYEES (
            ID int(11) UNSIGNED AUTO_INCREMENT PRIMARY KEY,
            NAME VARCHAR(45),
            ADDRESS VARCHAR(90)
        )";

        if(!mysqli_query($connection, $query)) echo("<p>Error creating table.</p>");
    }
}

/* Check for the existence of a table. */
function TableExists($tableName, $connection, $dbName) {
    $t = mysqli_real_escape_string($connection, $tableName);
    $d = mysqli_real_escape_string($connection, $dbName);

    $checktable = mysqli_query($connection,
        "SELECT TABLE_NAME FROM information_schema.TABLES WHERE TABLE_NAME = '$t' AND
        TABLE_SCHEMA = '$d'");

    if(mysqli_num_rows($checktable) > 0) return true;

    return false;
}
?>
```

8. Save and close the SamplePage.php file.
9. Verify that your web server successfully connects to your DB instance by opening a web browser and browsing to <http://EC2 instance endpoint/SamplePage.php>, for example: <http://ec2-55-122-41-31.us-west-2.compute.amazonaws.com/SamplePage.php>.

You can use SamplePage.php to add data to your DB instance. The data that you add is then displayed on the page. To verify that the data was inserted into the table, you can install MySQL on the Amazon EC2 instance, connect to the DB instance, and query the table.

To make sure that your DB instance is as secure as possible, verify that sources outside of the VPC can't connect to your DB instance.

After you have finished testing your web server and your database, you should delete your DB instance and your Amazon EC2 instance.

- To delete a DB instance, follow the instructions in [Deleting a DB instance \(p. 324\)](#). You don't need to create a final snapshot.
- To terminate an Amazon EC2 instance, follow the instruction in [Terminate your instance](#) in the *Amazon EC2 User Guide*.

Amazon RDS Tutorials

The AWS documentation includes several tutorials that guide you through common Amazon RDS use cases. Many of these tutorials show you how to use Amazon RDS with other AWS services.

Note

You can find more tutorials at the [AWS Database Blog](#). For information about training, see [AWS Training and Certification](#).

Tutorials in this guide

The following tutorials in this guide show you how to perform common tasks with Amazon RDS:

- [Tutorial: Create an Amazon VPC for use with a DB instance \(p. 1737\)](#)

Learn how to include a DB instance in an Amazon virtual private cloud (VPC) that shares data with a web server that is running on an Amazon EC2 instance in the same VPC.

- [Tutorial: Create a web server and an Amazon RDS DB instance \(p. 108\)](#)

Learn how to install an Apache web server with PHP and create a MySQL database. The web server runs on an Amazon EC2 instance using Amazon Linux, and the MySQL database is a MySQL DB instance. Both the Amazon EC2 instance and the DB instance run in an Amazon VPC.

- [Tutorial: Restore a DB instance from a DB snapshot \(p. 394\)](#)

Learn how to restore a DB instance from a DB snapshot.

- [Tutorial: Use tags to specify which DB instances to stop \(p. 304\)](#)

Learn how to use tags to specify which DB instances to stop.

- [Tutorial: Log the state of an Amazon RDS instance using EventBridge \(p. 554\)](#)

Learn how to log a DB instance stage change using Amazon EventBridge and AWS Lambda.

Tutorials in other AWS guides

The following tutorials in other AWS guides show you how to perform common tasks with Amazon RDS:

- [Tutorial: Rotating a Secret for an AWS Database](#) in the *AWS Secrets Manager User Guide*

Learn how to create a secret for an AWS database and configure the secret to rotate on a schedule. You trigger one rotation manually, and then confirm that the new version of the secret continues to provide access.

- [Tutorial: Configuring a Lambda function to access Amazon RDS in an Amazon VPC](#) in the *AWS Lambda Developer Guide*

Learn how to create a Lambda function to access a database, create a table, add a few records, and retrieve the records from the table. You also learn how to invoke the Lambda function and verify the query results.

- [Tutorials and samples](#) in the *AWS Elastic Beanstalk Developer Guide*

Learn how to deploy applications that use Amazon RDS databases with AWS Elastic Beanstalk.

- [Using Data from an Amazon RDS Database to Create an Amazon ML Datasource in the Amazon Machine Learning Developer Guide](#)

Learn how to create an Amazon Machine Learning (Amazon ML) datasource object from data stored in a MySQL DB instance.

- [Manually Enabling Access to an Amazon RDS Instance in a VPC in the Amazon QuickSight User Guide](#)

Learn how to enable Amazon QuickSight access to an Amazon RDS DB instance in a VPC.

Best practices for Amazon RDS

Learn best practices for working with Amazon RDS. As new best practices are identified, we will keep this section up to date.

Note

For common recommendations for Amazon RDS, see [Using Amazon RDS recommendations \(p. 407\)](#).

Amazon RDS basic operational guidelines

The following are basic operational guidelines that everyone should follow when working with Amazon RDS. Note that the Amazon RDS Service Level Agreement requires that you follow these guidelines:

- Monitor your memory, CPU, and storage usage. Amazon CloudWatch can be set up to notify you when usage patterns change or when you approach the capacity of your deployment, so that you can maintain system performance and availability.
- Scale up your DB instance when you are approaching storage capacity limits. You should have some buffer in storage and memory to accommodate unforeseen increases in demand from your applications.
- Enable automatic backups and set the backup window to occur during the daily low in write IOPS. That's when a backup is least disruptive to your database usage.
- If your database workload requires more I/O than you have provisioned, recovery after a failover or database failure will be slow. To increase the I/O capacity of a DB instance, do any or all of the following:
 - Migrate to a different DB instance class with high I/O capacity.
 - Convert from magnetic storage to either General Purpose or Provisioned IOPS storage, depending on how much of an increase you need. For information on available storage types, see [Amazon RDS storage types \(p. 40\)](#).

If you convert to Provisioned IOPS storage, make sure you also use a DB instance class that is optimized for Provisioned IOPS. For information on Provisioned IOPS, see [Provisioned IOPS SSD storage \(p. 42\)](#).

- If you are already using Provisioned IOPS storage, provision additional throughput capacity.
- If your client application is caching the Domain Name Service (DNS) data of your DB instances, set a time-to-live (TTL) value of less than 30 seconds. Because the underlying IP address of a DB instance can change after a failover, caching the DNS data for an extended time can lead to connection failures if your application tries to connect to an IP address that no longer is in service.
- Test failover for your DB instance to understand how long the process takes for your particular use case and to ensure that the application that accesses your DB instance can automatically connect to the new DB instance after failover occurs.

DB instance RAM recommendations

An Amazon RDS performance best practice is to allocate enough RAM so that your *working set* resides almost completely in memory. The working set is the data and indexes that are frequently in use on your instance. The more you use the DB instance, the more the working set will grow.

To tell if your working set is almost all in memory, check the ReadIOPS metric (using Amazon CloudWatch) while the DB instance is under load. The value of ReadIOPS should be small and stable. If scaling up the DB instance class—to a class with more RAM—results in a dramatic drop in ReadIOPS, your working set was not almost completely in memory. Continue to scale up until ReadIOPS no longer drops dramatically after a scaling operation, or ReadIOPS is reduced to a very small amount. For information on monitoring a DB instance's metrics, see [Viewing DB instance metrics \(p. 548\)](#).

Using Enhanced Monitoring to identify operating system issues

When Enhanced Monitoring is enabled, Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view the metrics for your DB instance using the console, or consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice. For more information about Enhanced Monitoring, see [Using Enhanced Monitoring \(p. 471\)](#).

Using metrics to identify performance issues

To identify performance issues caused by insufficient resources and other common bottlenecks, you can monitor the metrics available for your Amazon RDS DB instance.

Viewing performance metrics

You should monitor performance metrics on a regular basis to see the average, maximum, and minimum values for a variety of time ranges. If you do so, you can identify when performance is degraded. You can also set Amazon CloudWatch alarms for particular metric thresholds so you are alerted if they are reached.

To troubleshoot performance issues, it's important to understand the baseline performance of the system. When you set up a new DB instance and get it running with a typical workload, you should

capture the average, maximum, and minimum values of all of the performance metrics at a number of different intervals (for example, one hour, 24 hours, one week, two weeks) to get an idea of what is normal. It helps to get comparisons for both peak and off-peak hours of operation. You can then use this information to identify when performance is dropping below standard levels.

To view performance metrics

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose a DB instance.
3. Choose **Monitoring**. The first eight performance metrics display. The metrics default to showing information for the current day.
4. Use the numbered buttons at top right to page through the additional metrics, or choose adjust the settings to see more metrics.
5. Choose a performance metric to adjust the time range in order to see data for other than the current day. You can change the **Statistic**, **Time Range**, and **Period** values to adjust the information displayed. For example, to see the peak values for a metric for each day of the last two weeks, set **Statistic** to **Maximum**, **Time Range** to **Last 2 Weeks**, and **Period** to **Day**.

Note

Changing the **Statistic**, **Time Range**, and **Period** values changes them for all metrics. The updated values persist for the remainder of your session or until you change them again.

You can also view performance metrics using the CLI or API. For more information, see [Viewing DB instance metrics \(p. 548\)](#).

To set a CloudWatch alarm

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose a DB instance.
3. Choose **Logs & events**.
4. In the **CloudWatch alarms** section, choose **Create alarm**.

Create alarm

You can use CloudWatch alarms to be notified automatically whenever metric data reaches a level you define.

Settings

[Refresh](#)

To edit an alarm, first choose whom to notify and then define when the notification should be sent.

5. For **Send notifications**, choose **Yes**, and for **Send notifications to**, choose **New email or SMS topic**.
6. For **Topic name**, enter a name for the notification, and for **With these recipients**, enter a comma-separated list of email addresses and phone numbers.
7. For **Metric**, choose the alarm statistic and metric to set.
8. For **Threshold**, specify whether the metric must be greater than, less than, or equal to the threshold, and specify the threshold value.
9. For **Evaluation period**, choose the evaluation period for the alarm, and for **consecutive period(s) of**, choose the period during which the threshold must have been reached in order to trigger the alarm.
10. For **Name of alarm**, enter a name for the alarm.
11. Choose **Create Alarm**.

The alarm appears in the **CloudWatch alarms** section.

Evaluating performance metrics

A DB instance has a number of different categories of metrics, and how to determine acceptable values depends on the metric.

CPU

- CPU Utilization – Percentage of computer processing capacity used.

Memory

- Freeable Memory – How much RAM is available on the DB instance, in megabytes. The red line in the Monitoring tab metrics is marked at 75% for CPU, Memory and Storage Metrics. If instance memory consumption frequently crosses that line, then this indicates that you should check your workload or upgrade your instance.
- Swap Usage – How much swap space is used by the DB instance, in megabytes.

Disk space

- Free Storage Space – How much disk space is not currently being used by the DB instance, in megabytes.

Input/output operations

- Read IOPS, Write IOPS – The average number of disk read or write operations per second.
- Read Latency, Write Latency – The average time for a read or write operation in milliseconds.
- Read Throughput, Write Throughput – The average number of megabytes read from or written to disk per second.
- Queue Depth – The number of I/O operations that are waiting to be written to or read from disk.

Network traffic

- Network Receive Throughput, Network Transmit Throughput – The rate of network traffic to and from the DB instance in bytes per second.

Database connections

- DB Connections – The number of client sessions that are connected to the DB instance.

For more detailed individual descriptions of the performance metrics available, see [Monitoring Amazon RDS metrics with Amazon CloudWatch \(p. 540\)](#).

Generally speaking, acceptable values for performance metrics depend on what your baseline looks like and what your application is doing. Investigate consistent or trending variances from your baseline. Advice about specific types of metrics follows:

- **High CPU or RAM consumption** – High values for CPU or RAM consumption might be appropriate, provided that they are in keeping with your goals for your application (like throughput or concurrency) and are expected.

- **Disk space consumption** – Investigate disk space consumption if space used is consistently at or above 85 percent of the total disk space. See if it is possible to delete data from the instance or archive data to a different system to free up space.
- **Network traffic** – For network traffic, talk with your system administrator to understand what expected throughput is for your domain network and Internet connection. Investigate network traffic if throughput is consistently lower than expected.
- **Database connections** – Consider constraining database connections if you see high numbers of user connections in conjunction with decreases in instance performance and response time. The best number of user connections for your DB instance will vary based on your instance class and the complexity of the operations being performed. You can determine the number of database connections by associating your DB instance with a parameter group where the *User Connections* parameter is set to other than 0 (unlimited). You can either use an existing parameter group or create a new one. For more information, see [Working with DB parameter groups \(p. 228\)](#).
- **IOPS metrics** – The expected values for IOPS metrics depend on disk specification and server configuration, so use your baseline to know what is typical. Investigate if values are consistently different than your baseline. For best IOPS performance, make sure your typical working set will fit into memory to minimize read and write operations.

For issues with any performance metrics, one of the first things you can do to improve performance is tune the most used and most expensive queries to see if that lowers the pressure on system resources. For more information, see [Tuning queries \(p. 133\)](#)

If your queries are tuned and an issue persists, consider upgrading your Amazon RDS [DB instance classes \(p. 7\)](#) to one with more of the resource (CPU, RAM, disk space, network bandwidth, I/O capacity) that is related to the issue you are experiencing.

Tuning queries

One of the best ways to improve DB instance performance is to tune your most commonly used and most resource-intensive queries to make them less expensive to run.

MySQL Query Tuning

Go to [Optimizing SELECT statements](#) in the MySQL documentation for more information on writing queries for better performance. You can also go to [MySQL performance tuning and optimization resources](#) for additional query tuning resources.

Oracle Query Tuning

Go to the [Database SQL Tuning Guide](#) in the Oracle documentation for more information on writing and analyzing queries for better performance.

SQL Server Query Tuning

Go to [Analyzing a query](#) in the SQL Server documentation to improve queries for SQL Server DB instances. You can also use the execution-, index- and I/O-related data management views (DMVs) described in the [Dynamic management views and functions](#) documentation to troubleshoot SQL Server query issues.

A common aspect of query tuning is creating effective indexes. You can use the [Database engine Tuning Advisor](#) to get potential index improvements for your DB instance. For more information, see [Analyzing your database workload on an Amazon RDS DB instance with SQL Server Tuning Advisor \(p. 812\)](#).

PostgreSQL Query Tuning

Go to [Using EXPLAIN](#) in the PostgreSQL documentation to learn how to analyze a query plan. You can use this information to modify a query or underlying tables in order to improve query performance. You

can also go to [Controlling the planner with explicit JOIN clauses](#) to get tips about how to specify joins in your query for the best performance.

MariaDB Query Tuning

Go to [Query optimizations](#) in the MariaDB documentation for more information on writing queries for better performance.

Best practices for working with MySQL storage engines

Both table sizes and number of tables in a MySQL database can affect performance.

Table size

Typically, operating system constraints on file sizes determine the effective maximum table size for MySQL databases. So, the limits usually aren't determined by internal MySQL constraints.

On a MySQL DB instance, avoid tables in your database growing too large. Although the general storage limit is 64 TiB, provisioned storage limits restrict the maximum size of a MySQL table file to 16 TiB. Partition your large tables so that file sizes are well under the 16 TiB limit. This approach can also improve performance and recovery time. For more information, see [MySQL file size limits in Amazon RDS \(p. 950\)](#).

Very large tables (greater than 100 GB in size) can negatively affect performance for both reads and writes (including DML statements and especially DDL statements). Indexes on large tables can significantly improve select performance, but they can also degrade the performance of DML statements. DDL statements, such as `ALTER TABLE`, can be significantly slower for the large tables because those operations might completely rebuild a table in some cases. These DDL statements might lock the tables for the duration of the operation.

The amount of memory required by MySQL for reads and writes depends on the tables involved in the operations. It is a best practice to have at least enough RAM to hold the indexes of *actively used* tables. To find the ten largest tables and indexes in a database, use the following query:

```
SELECT CONCAT(table_schema, '.', table_name),
       CONCAT(ROUND(table_rows / 1000000, 2), 'M')                                rows,
       CONCAT(ROUND(data_length / ( 1024 * 1024 * 1024 ), 2), 'G')                  DATA,
       CONCAT(ROUND(index_length / ( 1024 * 1024 * 1024 ), 2), 'G')                  idx,
       CONCAT(ROUND(( data_length + index_length ) / ( 1024 * 1024 * 1024 ), 2), 'G') total_size,
       ROUND(index_length / data_length, 2)                                         idxfrac
  FROM   information_schema.TABLES
 ORDER  BY data_length + index_length DESC
 LIMIT  10;
```

Number of tables

While the underlying file system might have a limit on the number of files that represent tables, MySQL has no limit on the number of tables. However, the total number of tables in the MySQL InnoDB storage engine can contribute to the performance degradation, regardless of the size of those tables. To limit the operating system impact, you can split the tables across multiple databases in the same MySQL DB instance. Doing so might limit the number of files in a directory but won't solve the overall problem.

When there is performance degradation because of a large number of tables (more than 10 thousand), it is caused by MySQL working with storage files, including opening and closing them. To address this issue, you can increase the size of the `table_open_cache` and `table_definition_cache` parameters. However, increasing the values of those parameters might significantly increase the amount of memory MySQL uses, and might even use all of the available memory. For more information, see [How MySQL Opens and Closes Tables](#) in the MySQL documentation.

In addition, too many tables can significantly affect MySQL startup time. Both a clean shutdown and restart and a crash recovery can be affected, especially in versions prior to MySQL 8.0.

We recommend having fewer than ten thousand tables total across all of the databases in a DB instance. For a use case with a large number of tables in a MySQL database, see [One Million Tables in MySQL 8.0](#).

Storage engine

The point-in-time restore and snapshot restore features of Amazon RDS for MySQL require a crash-recoverable storage engine and are supported for the InnoDB storage engine only. Although MySQL supports multiple storage engines with varying capabilities, not all of them are optimized for crash recovery and data durability. For example, the MyISAM storage engine does not support reliable crash recovery and might prevent a Point-In-Time Restore or snapshot restore from working as intended. This might result in lost or corrupt data when MySQL is restarted after a crash.

InnoDB is the recommended and supported storage engine for MySQL DB instances on Amazon RDS. InnoDB instances can also be migrated to Aurora, while MyISAM instances can't be migrated. However, MyISAM performs better than InnoDB if you require intense, full-text search capability. If you still choose to use MyISAM with Amazon RDS, following the steps outlined in [Automated backups with unsupported MySQL storage engines \(p. 336\)](#) can be helpful in certain scenarios for snapshot restore functionality.

If you want to convert existing MyISAM tables to InnoDB tables, you can use the process outlined in the [MySQL documentation](#). MyISAM and InnoDB have different strengths and weaknesses, so you should fully evaluate the impact of making this switch on your applications before doing so.

In addition, Federated Storage Engine is currently not supported by Amazon RDS for MySQL.

Best practices for working with MariaDB storage engines

Both table sizes and number of tables in a MariaDB database can affect performance.

Table size

Typically, operating system constraints on file sizes determine the effective maximum table size for MariaDB databases. So, the limits usually aren't determined by internal MariaDB constraints.

On a MariaDB DB instance, avoid tables in your database growing too large. Although the general storage limit is 64 TiB, provisioned storage limits restrict the maximum size of a MariaDB table file to 16 TiB. Partition your large tables so that file sizes are well under the 16 TiB limit. This approach can also improve performance and recovery time.

Very large tables (greater than 100 GB in size) can negatively affect performance for both reads and writes (including DML statements and especially DDL statements). Indexes on large tables can significantly improve select performance, but they can also degrade the performance of DML

statements. DDL statements, such as `ALTER TABLE`, can be significantly slower for the large tables because those operations might completely rebuild a table in some cases. These DDL statements might lock the tables for the duration of the operation.

The amount of memory required by MariaDB for reads and writes depends on the tables involved in the operations. It is a best practice to have at least enough RAM to hold the indexes of *actively* used tables. To find the ten largest tables and indexes in a database, use the following query:

```
SELECT CONCAT(table_schema, '.', table_name),
       CONCAT(ROUND(table_rows / 1000000, 2), 'M')                                     rows,
       CONCAT(ROUND(data_length / ( 1024 * 1024 * 1024 ), 2), 'G')                      DATA,
       CONCAT(ROUND(index_length / ( 1024 * 1024 * 1024 ), 2), 'G')                     idx,
       CONCAT(ROUND(( data_length + index_length ) / ( 1024 * 1024 * 1024 ), 2), 'G')    total_size,
       ROUND(index_length / data_length, 2)                                              idxfrac
  FROM  information_schema.TABLES
 ORDER  BY data_length + index_length DESC
 LIMIT  10;
```

Number of tables

While the underlying file system might have a limit on the number of files that represent tables, MariaDB has no limit on the number of tables. However, the total number of tables in the MariaDB InnoDB storage engine can contribute to the performance degradation, regardless of the size of those tables. To limit the operating system impact, you can split the tables across multiple databases in the same MariaDB DB instance. Doing so might limit the number of files in a directory but won't solve the overall problem.

When there is performance degradation because of a large number of tables (more than 10 thousand), it is caused by MariaDB working with storage files, including opening and closing them. To address this issue, you can increase the size of the `table_open_cache` and `table_definition_cache` parameters. However, increasing the values of those parameters might significantly increase the amount of memory MariaDB uses, and might even use all of the available memory. For more information, see [Optimizing table_open_cache](#) in the MariaDB documentation.

In addition, too many tables can significantly affect MariaDB startup time. Both a clean shutdown and restart and a crash recovery can be affected. We recommend having fewer than ten thousand tables total across all of the databases in a DB instance.

Storage engine

The point-in-time restore and snapshot restore features of Amazon RDS for MariaDB require a crash-recoverable storage engine. Although MariaDB supports multiple storage engines with varying capabilities, not all of them are optimized for crash recovery and data durability. For example, although Aria is a crash-safe replacement for MyISAM, it might still prevent a point-in-time restore or snapshot restore from working as intended. This might result in lost or corrupt data when MariaDB is restarted after a crash. InnoDB (for version 10.2 and higher) and XtraDB (for version 10.0 and 10.1) are the recommended and supported storage engines for MariaDB DB instances on Amazon RDS. If you still choose to use Aria with Amazon RDS, following the steps outlined in [Automated backups with unsupported MariaDB storage engines \(p. 336\)](#) can be helpful in certain scenarios for snapshot restore functionality.

If you want to convert existing MyISAM tables to InnoDB tables, you can use the process outlined in the [MariaDB documentation](#). MyISAM and InnoDB have different strengths and weaknesses, so you should fully evaluate the impact of making this switch on your applications before doing so.

Best practices for working with Oracle

For information about best practices for working with Amazon RDS for Oracle, see [Best practices for running Oracle database on Amazon Web Services](#).

A 2020 AWS virtual workshop included a presentation on running production Oracle databases on Amazon RDS. A video of the presentation is available [here](#).

Best practices for working with PostgreSQL

Two important areas where you can improve performance with PostgreSQL on Amazon RDS are when loading data into a DB instance and when using the PostgreSQL autovacuum feature. The following sections cover some of the practices we recommend for these areas.

Loading data into a PostgreSQL DB instance

When loading data into an Amazon RDS PostgreSQL DB instance, you should modify your DB instance settings and your DB parameter group values to allow for the most efficient importing of data into your DB instance.

Modify your DB instance settings to the following:

- Disable DB instance backups (set `backup_retention` to 0)
- Disable Multi-AZ

Modify your DB parameter group to include the following settings. You should test the parameter settings to find the most efficient settings for your DB instance:

- Increase the value of the `maintenance_work_mem` parameter. For more information about PostgreSQL resource consumption parameters, see the [PostgreSQL documentation](#).
- Increase the value of the `checkpoint_segments` and `checkpoint_timeout` parameters to reduce the number of writes to the wal log.
- Disable the `synchronous_commit` parameter (do not turn off FSYNC).
- Disable the PostgreSQL autovacuum parameter.
- Make sure none of the tables you are importing are unlogged. Data stored in unlogged tables can be lost during a failover. For more information, see [CREATE TABLE UNLOGGED](#).

Use the `pg_dump -Fc` (compressed) or `pg_restore -j` (parallel) commands with these settings.

After the load operation completes, return your DB instance and DB parameters to their normal settings.

Working with the PostgreSQL autovacuum feature

The autovacuum feature for PostgreSQL databases is a feature that we strongly recommend you use to maintain the health of your PostgreSQL DB instance. Autovacuum automates the execution of the `VACUUM` and `ANALYZE` command; using autovacuum is required by PostgreSQL, not imposed by Amazon RDS, and its use is critical to good performance. The feature is enabled by default for all new Amazon RDS PostgreSQL DB instances, and the related configuration parameters are appropriately set by default.

Your database administrator needs to know and understand this maintenance operation. For the PostgreSQL documentation on autovacuum, see [Routine vacuuming](#).

Autovacuum is not a "resource free" operation, but it works in the background and yields to user operations as much as possible. When enabled, autovacuum checks for tables that have had a large number of updated or deleted tuples. It also protects against loss of very old data due to transaction ID wraparound. For more information, see [Preventing transaction ID wraparound failures](#).

Autovacuum should not be thought of as a high-overhead operation that can be reduced to gain better performance. On the contrary, tables that have a high velocity of updates and deletes will quickly deteriorate over time if autovacuum is not run.

Important

Not running autovacuum can result in an eventual required outage to perform a much more intrusive vacuum operation. When an Amazon RDS PostgreSQL DB instance becomes unavailable because of an over conservative use of autovacuum, the PostgreSQL database will shut down to protect itself. At that point, Amazon RDS must perform a single-user-mode full vacuum directly on the DB instance , which can result in a multi-hour outage. Thus, we strongly recommend that you do not turn off autovacuum, which is enabled by default.

The autovacuum parameters determine when and how hard autovacuum works. The `autovacuum_vacuum_threshold` and `autovacuum_vacuum_scale_factor` parameters determine when autovacuum is run. The `autovacuum_max_workers`, `autovacuum_nap_time`, `autovacuum_cost_limit`, and `autovacuum_cost_delay` parameters determine how hard autovacuum works. For more information about autovacuum, when it runs, and what parameters are required, see the [PostgreSQL documentation](#).

The following query shows the number of "dead" tuples in a table named `table1` :

```
PROMPT> select relname, n_dead_tup, last_vacuum, last_autovacuum from pg_catalog.pg_stat_all_tables where n_dead_tup > 0 and relname = 'table1';
```

The results of the query will resemble the following:

relname	n_dead_tup	last_vacuum	last_autovacuum
tasks	81430522		

(1 row)

Best practices for working with SQL Server

Best practices for a Multi-AZ deployment with a SQL Server DB instance include the following:

- Use Amazon RDS DB events to monitor failovers. For example, you can be notified by text message or email when a DB instance fails over. For more information about Amazon RDS events, see [Using Amazon RDS event notification \(p. 487\)](#).
- If your application caches DNS values, set time to live (TTL) to less than 30 seconds. Setting TTL as so is a good practice in case there is a failover, where the IP address might change and the cached value might no longer be in service.
- We recommend that you *do not* enable the following modes because they turn off transaction logging, which is required for Multi-AZ:
 - Simple recover mode
 - Offline mode
 - Read-only mode
- Test to determine how long it takes for your DB instance to failover. Failover time can vary due to the type of database, the instance class, and the storage type you use. You should also test your application's ability to continue working if a failover occurs.

- To shorten failover time, you should do the following:
 - Ensure that you have sufficient Provisioned IOPS allocated for your workload. Inadequate I/O can lengthen failover times. Database recovery requires I/O.
 - Use smaller transactions. Database recovery relies on transactions, so if you can break up large transactions into multiple smaller transactions, your failover time should be shorter.
- Take into consideration that during a failover, there will be elevated latencies. As part of the failover process, Amazon RDS automatically replicates your data to a new standby instance. This replication means that new data is being committed to two different DB instances, so there might be some latency until the standby DB instance has caught up to the new primary DB instance.
- Deploy your applications in all Availability Zones. If an Availability Zone does go down, your applications in the other Availability Zones will still be available.

When working with a Multi-AZ deployment of SQL Server, remember that Amazon RDS creates replicas for all SQL Server databases on your instance. If you don't want specific databases to have secondary replicas, set up a separate DB instance that doesn't use Multi-AZ for those databases.

Amazon RDS for SQL Server best practices video

The 2019 AWS re:Invent conference included a presentation on new features and best practices for working with SQL Server on Amazon RDS. A video of the presentation is available [here](#).

Working with DB parameter groups

We recommend that you try out DB parameter group changes on a test DB instance before applying parameter group changes to your production DB instances. Improperly setting DB engine parameters in a DB parameter group can have unintended adverse effects, including degraded performance and system instability. Always exercise caution when modifying DB engine parameters and back up your DB instance before modifying a DB parameter group.

For information about backing up your DB instance, see [Backing up and restoring an Amazon RDS DB instance \(p. 327\)](#).

Amazon RDS new features and best practices presentation video

The 2019 AWS re:Invent conference included a presentation on new Amazon RDS features and best practices for monitoring, analyzing, and tuning database performance using RDS. A video of the presentation is available [here](#).

Configuring an Amazon RDS DB instance

This section shows how to set up your Amazon RDS DB instance. Before creating a DB instance, decide on the DB instance class that will run the DB instance. Also, decide where the DB instance will run by choosing an AWS Region. Next, create the DB instance.

You can configure a DB instance with an option group and a DB parameter group.

- An *option group* specifies features, called options, that are available for a particular Amazon RDS DB instance.
- A *DB parameter group* acts as a container for engine configuration values that are applied to one or more DB instances.

The options and parameters that are available depend on the DB engine and DB engine version. You can specify an option group and a DB parameter group when you create a DB instance, or you can modify a DB instance to specify them.

Topics

- [Creating an Amazon RDS DB instance \(p. 141\)](#)
- [Connecting to an Amazon RDS DB instance \(p. 162\)](#)
- [Working with option groups \(p. 212\)](#)
- [Working with DB parameter groups \(p. 228\)](#)

Creating an Amazon RDS DB instance

The basic building block of Amazon RDS is the DB instance, where you create your databases. You choose the engine-specific characteristics of the DB instance when you create it. You also choose the storage capacity, CPU, memory, and so on, of the AWS instance on which the database server runs.

Important

Before you can create or connect to a DB instance, you must complete the tasks in [Setting up for Amazon RDS \(p. 67\)](#).

Console

You can create a DB instance by using the AWS Management Console with **Easy Create** enabled or not enabled. With **Easy Create** enabled, you specify only the DB engine type, DB instance size, and DB instance identifier. **Easy Create** uses the default setting for other configuration options. With **Easy Create** not enabled, you specify more configuration options when you create a database, including ones for availability, security, backups, and maintenance.

Note

In the following procedure, **Standard Create** is enabled, and **Easy Create** isn't enabled. This procedure uses Microsoft SQL Server as an example.

For examples that use **Easy Create** to walk you through creating and connecting to sample DB instances for each engine, see [Getting started with Amazon RDS \(p. 73\)](#). For an example that uses the original console to create a DB instance, see [Original console example \(p. 157\)](#).

To create a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**.
5. In **Choose a database creation method**, select **Standard Create**.
6. In **Engine options**, choose the engine type: MariaDB, Microsoft SQL Server, MySQL, Oracle, or PostgreSQL. **Microsoft SQL Server** is shown here.

Create database

Choose a database creation method Info

Standard Create

You set all of the configuration options, including ones for availability, security, backups, and maintenance.

Easy Create

Use recommended best-practice configurations. Some configuration options can be changed after the database is created.

Engine options

Engine type Info

Amazon Aurora

MySQL

MariaDB

PostgreSQL

Oracle

Microsoft SQL Server

Edition

SQL Server Express Edition

Affordable database management system that supports database sizes up to 10 GB.

SQL Server Web Edition

In accordance with Microsoft's licensing policies, it can only be used to support public and Internet-accessible webpages, websites, web applications, and web services.

SQL Server Standard Edition

Core data management and business intelligence capabilities for mission-critical applications and mixed workloads.

SQL Server Enterprise Edition

Comprehensive high-end capabilities for mission-critical applications with demanding database workloads and business intelligence requirements.

Version Info

SQL Server 2017 14.00.3010.1-1

7. For **Edition**, if you're using Oracle or SQL Server choose the DB engine edition that you want to use. MySQL has only one option for the edition, and MariaDB and PostgreSQL have none.
8. For **Version**, choose the engine version.
9. In **Templates**, choose the template that matches your use case. If you choose **Production**, the following are preselected in a later step:
 - **Multi-AZ failover option**
 - **Provisioned IOPS storage option**
 - **Enable deletion protection** option

We recommend these features for any production environment.

Note

Template choices vary by edition.

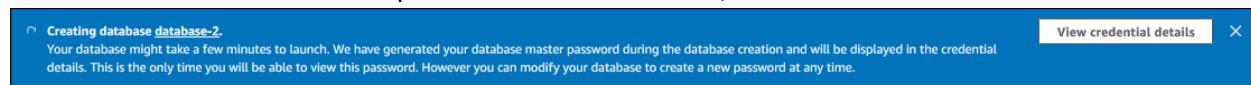

10. To enter your master password, do the following:
 - a. In the **Settings** section, open **Credential Settings**.
 - b. Clear the **Auto generate a password** check box.
 - c. (Optional) Change the **Master username** value and enter the same password in **Master password** and **Confirm password**.

By default, the new DB instance uses an automatically generated password for the master user.

11. For the remaining sections, specify your DB instance settings. For information about each setting, see [Settings for DB instances \(p. 145\)](#).
12. Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

Important

You can't view the master user password again. If you don't record it, you might have to change it. If you need to change the master user password after the DB instance is available, modify the DB instance to do so. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

13. For **Databases**, choose the name of the new DB instance.

On the RDS console, the details for the new DB instance appear. The DB instance has a status of **creating** until the DB instance is created and ready for use. When the state changes to **available**, you can connect to the DB instance. Depending on the DB instance class and storage allocated, it can take several minutes for the new instance to be available.

database-1				Modify	Actions ▾
Summary					
DB identifier	CPU	Info	Creating	Class	db.t2.micro
database-1		(?)		Region & AZ	-
Role	Current activity	Engine	SQL Server Express Edition	Maintenance & backups	Tags
Instance					
Connectivity & security		Monitoring	Logs & events	Configuration	Maintenance & backups

AWS CLI

To create a DB instance by using the AWS CLI, call the [create-db-instance](#) command with the following parameters. This example uses Microsoft SQL Server.

For information about each setting, see [Settings for DB instances \(p. 145\)](#).

- `--db-instance-identifier`
- `--db-instance-class`
- `--vpc-security-group-ids`
- `--db-subnet-group`
- `--engine`
- `--master-username`
- `--master-user-password`
- `--allocated-storage`
- `--backup-retention-period`

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --engine sqlserver-se \
  --db-instance-identifier mymssqlserver \
  --allocated-storage 250 \
  --db-instance-class db.t3.large \
  --vpc-security-group-ids mysecuritygroup \
  --db-subnet-group mydbsubnetgroup \
  --master-username masterawsuser \
  --master-user-password masteruserpassword \
  --backup-retention-period 3
```

For Windows:

```
aws rds create-db-instance ^
  --engine sqlserver-se ^
  --db-instance-identifier mydbinstance ^
  --allocated-storage 250 ^
  --db-instance-class db.t3.large ^
  --vpc-security-group-ids mysecuritygroup ^
  --db-subnet-group mydbsubnetgroup ^
  --master-username masterawsuser ^
  --master-user-password masteruserpassword ^
  --backup-retention-period 3
```

This command produces output similar to the following.

```
DBINSTANCE mydbinstance db.t3.large sqlserver-se 250 sa creating 3 **** n
10.50.2789
SECGROUP default active
PARAMGRP default.sqlserver-se-14 in-sync
```

RDS API

To create a DB instance by using the Amazon RDS API, call the [CreateDBInstance](#) operation with the following parameters.

For information about each setting, see [Settings for DB instances \(p. 145\)](#).

- `AllocatedStorage`
- `BackupRetentionPeriod`
- `DBInstanceClass`
- `DBInstanceIdentifier`
- `VpcSecurityGroupIds`
- `DBSubnetGroup`
- `Engine`
- `MasterUsername`
- `MasterUserPassword`

Settings for DB instances

In the following table, you can find details about settings that you choose when you create a DB instance. The table also shows the DB engines for which each setting is supported.

You can create a DB instance using the console, the `create-db-instance` CLI command, or the `CreateDBInstance` RDS API operation.

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Allocated storage	<p>The amount of storage to allocate for your DB instance (in gigabytes). In some cases, allocating a higher amount of storage for your DB instance than the size of your database can improve I/O performance.</p> <p>For more information, see Amazon RDS DB instance storage (p. 40).</p>	CLI option: <code>--allocated-storage</code> API parameter: <code>AllocatedStorage</code>	All
Auto minor version upgrade	<p>Enable auto minor version upgrade to enable your DB instance to receive preferred minor DB engine version upgrades automatically when they become available. Amazon RDS performs automatic minor version upgrades in the maintenance window.</p>	CLI option: <code>--auto-minor-version-upgrade</code> <code>--no-auto-minor-version-upgrade</code> API parameter: <code>AutoMinorVersionUpgrade</code>	All except SQL Server
Availability zone	<p>The Availability Zone for your DB instance. Use the default value of No Preference unless you want to specify an Availability Zone.</p> <p>For more information, see Regions, Availability Zones, and Local Zones (p. 49).</p>	CLI option: <code>--availability-zone</code> API parameter: <code>AvailabilityZone</code>	All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Backup replication	<p>Choose Enable replication to another AWS Region to create backups in an additional Region for disaster recovery.</p> <p>Then choose the Destination Region for the additional backups.</p>	<p>Not available when creating a DB instance. For information on enabling cross-Region backups using the AWS CLI or RDS API, see Enabling cross-Region automated backups (p. 338).</p>	Oracle
Backup retention period	<p>The number of days that you want automatic backups of your DB instance to be retained. For any nontrivial DB instance, set this value to 1 or greater.</p> <p>For more information, see Working with backups (p. 328).</p>	CLI option: <code>--backup-retention-period</code> API parameter: <code>BackupRetentionPeriod</code>	All
Backup window	<p>The time period during which Amazon RDS automatically takes a backup of your DB instance. Unless you have a specific time that you want to have your database backed up, use the default of No Preference.</p> <p>For more information, see Working with backups (p. 328).</p>	CLI option: <code>--preferred-backup-window</code> API parameter: <code>PreferredBackupWindow</code>	All
Character set	<p>The character set for your DB instance. The default value of AL32UTF8 for the DB character set is for the Unicode 5.0 UTF-8 Universal character set. You can't change the DB character set after you create the DB instance.</p> <p>The DB character set is different from the national character set, which is called the NCHAR character set. Unlike the DB character set, the NCHAR character set specifies the encoding for NCHAR data types (NCHAR, NVARCHAR2, and NCLOB) columns without affecting database metadata.</p> <p>For more information, see RDS for Oracle character sets (p. 996).</p>	CLI option: <code>--character-set-name</code> API parameter: <code>CharacterSetName</code>	Oracle
Collation	<p>A server-level collation for your DB instance.</p> <p>For more information, see Server-level collation for Microsoft SQL Server (p. 814).</p>	CLI option: <code>--character-set-name</code> API parameter: <code>CharacterSetName</code>	SQL Server

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Copy tags to snapshots	<p>This option copies any DB instance tags to a DB snapshot when you create a snapshot.</p> <p>For more information, see Tagging Amazon RDS resources (p. 299).</p>	CLI option: <code>--copy-tags-to-snapshot</code> <code>--no-copy-tags-to-snapshot</code> RDS API parameter: <code>CopyTagsToSnapshot</code>	All
Database port	<p>The port that you want to access the DB instance through. The default port is shown. If you use a DB security group with your DB instance, this port value must be the same one that you provided when creating the DB security group.</p> <p>Note The firewalls at some companies block connections to the default MariaDB, MySQL, and PostgreSQL ports. If your company firewall blocks the default port, enter another port for your DB instance.</p>	CLI option: <code>--port</code> RDS API parameter: <code>Port</code>	All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Database authentication	<p>The database authentication option that you want to use.</p> <p>Choose Password authentication to authenticate database users with database passwords only.</p> <p>Choose Password and IAM DB authentication to authenticate database users with database passwords and user credentials through IAM users and roles. For more information, see IAM database authentication for MySQL and PostgreSQL (p. 1660). This option is only supported for MySQL and PostgreSQL.</p> <p>Choose Password and Kerberos authentication to authenticate database users with database passwords and Kerberos authentication through an AWS Managed Microsoft AD created with AWS Directory Service. Next, choose the directory or choose Create a new Directory.</p> <p>For more information, see one of the following:</p> <ul style="list-style-type: none"> • Using Kerberos authentication for MySQL (p. 938) • Configuring Kerberos authentication for Amazon RDS for Oracle (p. 1014) • Using Kerberos authentication with Amazon RDS for PostgreSQL (p. 1520) 	<p>IAM:</p> <p>CLI option:</p> <pre>--enable-iam-database-authentication</pre> <p>RDS API parameter:</p> <pre>EnableIAMDatabaseAuthentication</pre> <p>Kerberos:</p> <p>CLI option:</p> <pre>--domain</pre> <pre>--domain-iam-role-name</pre> <p>RDS API parameter:</p> <pre>Domain</pre> <pre>DomainIAMRoleName</pre>	MySQL Oracle PostgreSQL
DB engine version	The version of database engine that you want to use.	<p>CLI option:</p> <pre>--engine-version</pre> <p>RDS API parameter:</p> <pre>EngineVersion</pre>	All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
DB instance class	<p>The configuration for your DB instance. For example, a <code>db.t3.small</code> instance class has 2 GiB memory, 2 vCPUs, 1 virtual core, a variable ECU, and a moderate I/O capacity.</p> <p>If possible, choose an instance class large enough that a typical query working set can be held in memory. When working sets are held in memory the system can avoid writing to disk, which improves performance.</p> <p>For more information, see DB instance classes (p. 7).</p>	CLI option: <code>--db-instance-class</code> RDS API parameter: <code>DBInstanceClass</code>	All
DB instance identifier	The name for your DB instance. Name your DB instances in the same way that you name your on-premises servers. Your DB instance identifier can contain up to 63 alphanumeric characters, and must be unique for your account in the AWS Region you chose. You can add some intelligence to the name, such as including the AWS Region and DB engine you chose, for example <code>sqlsrvr-instance1</code> .	CLI option: <code>--db-instance-identifier</code> RDS API parameter: <code>DBInstanceIdentifier</code>	All
DB parameter group	<p>A parameter group for your DB instance. You can choose the default parameter group or you can create a custom parameter group.</p> <p>For more information, see Working with DB parameter groups (p. 228).</p>	CLI option: <code>--db-parameter-group-name</code> RDS API parameter: <code>DBParameterGroupName</code>	All
Deletion protection	<p>Enable deletion protection to prevent your DB instance from being deleted. If you create a production DB instance with the AWS Management Console, deletion protection is enabled by default.</p> <p>For more information, see Deleting a DB instance (p. 324).</p>	CLI option: <code>--deletion-protection</code> <code>--no-deletion-protection</code> RDS API parameter: <code>DeletionProtection</code>	All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Encryption	<p>Enable Encryption to enable encryption at rest for this DB instance.</p> <p>For more information, see Encrypting Amazon RDS resources (p. 1630).</p>	<p>CLI option: <code>--storage-encrypted</code> <code>--no-storage-encrypted</code></p> <p>RDS API parameter: <code>StorageEncrypted</code></p>	All
Enhanced Monitoring	<p>Enable enhanced monitoring to enable gathering metrics in real time for the operating system that your DB instance runs on.</p> <p>For more information, see Using Enhanced Monitoring (p. 471).</p>	<p>CLI options: <code>--monitoring-interval</code> <code>--monitoring-role-arn</code></p> <p>RDS API parameters: <code>MonitoringInterval</code> <code>MonitoringRoleArn</code></p>	All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Initial database name	<p>The name for the database on your DB instance. If you don't provide a name, Amazon RDS doesn't create a database on the DB instance (except for Oracle and PostgreSQL). The name can't be a word reserved by the database engine, and has other constraints depending on the DB engine.</p> <p>MariaDB and MySQL:</p> <ul style="list-style-type: none"> • It must contain 1–64 alphanumeric characters. <p>Oracle:</p> <ul style="list-style-type: none"> • It must contain 1–8 alphanumeric characters. • It can't be <code>NULL</code>. The default value is <code>ORCL</code>. • It must begin with a letter. <p>PostgreSQL:</p> <ul style="list-style-type: none"> • It must contain 1–63 alphanumeric characters. • It must begin with a letter or an underscore. Subsequent characters can be letters, underscores, or digits (0–9). • The initial database name is <code>postgres</code>. 	<p>CLI option: <code>--db-name</code></p> <p>RDS API parameter: <code>DBName</code></p>	All except SQL Server
License	<p>The license model:</p> <ul style="list-style-type: none"> • Choose license-included for Microsoft SQL Server. • Choose license-included or bring-your-own-license for Oracle. 	<p>CLI option: <code>--license-model</code></p> <p>RDS API parameter: <code>LicenseModel</code></p>	SQL Server Oracle
Maintenance window	<p>The 30-minute window in which pending modifications to your DB instance are applied. If the time period doesn't matter, choose No Preference.</p> <p>For more information, see The Amazon RDS maintenance window (p. 268).</p>	<p>CLI option: <code>--preferred-maintenance-window</code></p> <p>RDS API parameter: <code>PreferredMaintenanceWindow</code></p>	All

Console setting	Setting description	CLI option and RDS API parameter	Supported DB engines
Master password	<p>The password for your master user account. The password has the following number of printable ASCII characters (excluding /, ", a space, and @) depending on the DB engine:</p> <ul style="list-style-type: none"> • Oracle: 8–30 • MariaDB and MySQL: 8–41 • SQL Server and PostgreSQL: 8–128 	<p>CLI option: <code>--master-user-password</code></p> <p>RDS API parameter: <code>MasterUserPassword</code></p>	All
Master username	<p>The name that you use as the master user name to log on to your DB instance with all database privileges.</p> <ul style="list-style-type: none"> • It can contain 1–16 alphanumeric characters and underscores. • Its first character must be a letter. • It can't be a word reserved by the database engine. <p>For more information on privileges granted to the master user, see the following topics:</p> <ul style="list-style-type: none"> • MariaDB security on Amazon RDS (p. 582) • Microsoft SQL Server security (p. 635) • MySQL security on Amazon RDS (p. 833) • Securing Oracle DB instance connections (p. 1010) • Using SSL with a PostgreSQL DB instance (p. 1513) 	<p>CLI option: <code>--master-username</code></p> <p>RDS API parameter: <code>MasterUsername</code></p>	All

VPC security group	<p>If you are a new customer to AWS, Create new to create a new VPC security group. Otherwise, Choose existing, then choose from security groups that you previously created.</p> <p>When you choose Create new in the RDS console, a new security group is created. This new security group has an inbound rule that allows access to the DB instance from the IP address detected in your browser.</p> <p>For more information, see Working with DB security groups (EC2-Classic platform) (p. 1704).</p>	<p>CLI option: <code>--vpc-security-group-ids</code></p> <p>RDS API parameter: <code>VpcSecurityGroupIds</code></p>	All

Original console example

You can create a DB instance with the original AWS Management Console. This example uses Microsoft SQL Server.

To launch a SQL Server DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region in which you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
If the navigation pane is closed, choose the menu icon at the top left to open it.
4. Choose **Create database** to open the **Select engine** page.
5. Choose the **Microsoft SQL Server** icon.

Select engine

Engine options

Amazon Aurora
Amazon Aurora

MySQL

MariaDB

PostgreSQL

Oracle
ORACLE

Microsoft SQL Server

Microsoft SQL Server

Edition

SQL Server Express Edition
Affordable database management system that supports database sizes up to 10 GiB.

SQL Server Web Edition
In accordance with Microsoft's licensing policies, it can only be used to support public and Internet-accessible webpages, websites, web applications, and web services.

SQL Server Standard Edition
Core data management and business intelligence capabilities for mission-critical applications and mixed workloads.

SQL Server Enterprise Edition
Comprehensive high-end capabilities for mission-critical applications with demanding database workloads and business intelligence requirements.

Aurora global database feature is now available.
This feature is now available in our new database creation flow.

[Try it now](#)

Only enable options eligible for RDS Free Usage Tier [Info](#)

[Cancel](#) **Next**

6. Choose the SQL Server DB engine edition that you want to use. The SQL Server editions that are available vary by AWS Region.
7. For some editions, the **Use Case** step asks if you are planning to use the DB instance you are creating for production. If you are, choose **Production**. If you choose **Production**, the following are all preselected in a later step:
 - Multi-AZ failover option

- **Provisioned IOPS** storage option
- **Enable deletion protection** option

We recommend these features for any production environment.

8. Choose **Next** to continue. The **Specify DB Details** page appears.

On the **Specify DB Details** page, specify your DB instance information. For information about each setting, see [Settings for DB instances \(p. 145\)](#).

9. Choose **Next** to continue. The **Configure Advanced Settings** page appears.

On the **Configure Advanced Settings** page, provide additional information that Amazon RDS needs to launch the DB instance. For information about each setting, see [Settings for DB instances \(p. 145\)](#).

Configure advanced settings

Network & Security

Virtual Private Cloud (VPC) [Info](#)

VPC defines the virtual networking environment for this DB instance.

[C](#)

Only VPCs with a corresponding DB subnet group are listed.

Subnet group [Info](#)

DB subnet group that defines which subnets and IP ranges the DB instance can use in the VPC you selected.

[C](#)

Public accessibility [Info](#)

Yes

EC2 instances and devices outside of the VPC hosting the DB instance will connect to the DB instances. You must also select one or more VPC security groups that specify which EC2 instances and devices can connect to the DB instance.

No

DB instance will not have a public IP address assigned. No EC2 instance or devices outside of the VPC will be able to connect.

Availability zone [Info](#)

[C](#)

VPC security groups

Security groups have rules authorizing connections from all the EC2 instances and devices that need to access the DB instance.

Create new VPC security group

Choose existing VPC security groups

10. Choose **Launch DB Instance**.

11. On the final page of the wizard, choose **Close**.

On the RDS console, the new DB instance appears in the list of DB instances. The DB instance has a status of **creating** until the DB instance is ready to use. When the state changes to **available**, you can connect to the DB instance. Depending on the DB instance class and the amount of storage, it can take up to 20 minutes before the new instance is available.

The screenshot shows the 'Databases' section of the Amazon RDS console. At the top left, there's a breadcrumb navigation: 'RDS > Databases'. Below it is a title 'Databases' and a search bar labeled 'Filter databases'. A table lists five databases:

	DB Name	Role	Engine	Region
○	mymariadb	Instance	MariaDB	us-east-1
○	myoracledb	Instance	Oracle Enterprise Edition	us-east-1
○	mypostgresql	Instance	PostgreSQL	us-east-1
○	mysqldb	Instance	SQL Server Express Edition	us-east-1
○	testauroramysql-cl	Regional	Aurora MySQL	us-east-1

Connecting to an Amazon RDS DB instance

Before you can connect to a DB instance, you must create the DB instance. For information, see [Creating an Amazon RDS DB instance \(p. 141\)](#). After Amazon RDS provisions your DB instance, you can use any standard client application or utility for your DB engine to connect to the DB instance. In the connection string, you specify the DNS address from the DB instance endpoint as the host parameter, and specify the port number from the DB instance endpoint as the port parameter.

Finding the connection information for an Amazon RDS DB instance

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, for a MySQL DB instance, suppose that the endpoint value is `mydb.123456789012.us-east-1.rds.amazonaws.com`. In this case, the port value is 3306, and the database user is `admin`. Given this information, you specify the following values in a connection string:

- For host or host name or DNS name, specify `mydb.123456789012.us-east-1.rds.amazonaws.com`.
- For port, specify 3306.
- For user, specify `admin`.

The endpoint is unique for each DB instance, and the values of the port and user can vary. The following list shows the most common port for each DB engine:

- MariaDB – 3306
- Microsoft SQL Server – 1433
- MySQL – 3306
- Oracle – 1521
- PostgreSQL – 5432

To connect to a DB instance, use any client for a DB engine. For example, you might use the `mysql` utility to connect to a MariaDB or MySQL DB instance. You might use Microsoft SQL Server Management Studio to connect to a SQL Server DB instance. You might use Oracle SQL Developer to connect to an Oracle DB instance, or the `psql` command line utility to connect to a PostgreSQL DB instance.

To find the connection information for a DB instance, you can use the AWS Management Console, the AWS Command Line Interface (AWS CLI) [describe-db-instances](#) command, or the Amazon RDS API [DescribeDBInstances](#) operation to list its details.

Console

To find the connection information for a DB instance in the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases** to display a list of your DB instances.
3. Choose the name of the DB instance to display its details.
4. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

RDS > Databases > mydb

mydb

Summary

DB identifier	mydb	CPU	2.33%
Role	Instance	Current activity	0 Connections

Connectivity & security | Monitoring | Logs & events | Configuration

Connectivity & security

Endpoint & port	Network
Endpoint	Available
mydb. [REDACTED].us-east-1.rds.amazonaws.com	us-eas
Port	VPC
3306	vpc-65
Subnet	default
Security groups	[REDACTED]

5. If you need to find the master user name, choose the **Configuration** tab and view the **Master username** value.

AWS CLI

To find the connection information for a DB instance by using the AWS CLI, call the [describe-db-instances](#) command. In the call, query for the DB instance ID, endpoint, port, and master user name.

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
--query "[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

For Windows:

```
aws rds describe-db-instances ^
--query "[].[DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername]"
```

Your output should be similar to the following.

```
[  
  [  
    "mydb",  
    "mydb.123456789012.us-east-1.rds.amazonaws.com",  
    3306,  
    "admin"  
  ],  
  [  
    "myoracledb",  
    "myoracledb.123456789012.us-east-1.rds.amazonaws.com",  
    1521,  
    "dbadmin"  
  ],  
  [  
    "mypostgresql",  
    "mypostgresql.123456789012.us-east-1.rds.amazonaws.com",  
    5432,  
    "postgresadmin"  
  ]  
]
```

RDS API

To find the connection information for a DB instance by using the Amazon RDS API, call the [DescribeDBInstances](#) operation. In the output, find the values for the endpoint address, endpoint port, and master user name.

Database authentication options

Amazon RDS supports the following ways to authenticate database users:

- **Password authentication** – Your DB instance performs all administration of user accounts. You create users and specify passwords with SQL statements. The SQL statements you can use depend on your DB engine.
- **AWS Identity and Access Management (IAM) database authentication** – You don't need to use a password when you connect to a DB instance. Instead, you use an authentication token.
- **Kerberos authentication** – You use external authentication of database users using Kerberos and Microsoft Active Directory. Kerberos is a network authentication protocol that uses tickets and symmetric-key cryptography to eliminate the need to transmit passwords over the network. Kerberos has been built into Active Directory and is designed to authenticate users to network resources, such as databases.

IAM database authentication and Kerberos authentication are available only for specific DB engines and versions.

For more information, see [Database authentication with Amazon RDS \(p. 1628\)](#).

Encrypted connections

You can use Secure Socket Layer (SSL) or Transport Layer Security (TLS) from your application to encrypt a connection to a DB instance. Each DB engine has its own process for implementing SSL/TLS. For more information, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 1634\)](#).

Scenarios for accessing a DB instance in a VPC

Using Amazon Virtual Private Cloud (Amazon VPC), you can launch AWS resources, such as Amazon RDS DB instances, into a virtual private cloud (VPC). When you use Amazon VPC, you have control over your virtual networking environment. You can choose your own IP address range, create subnets, and configure routing and access control lists.

A VPC security group controls access to DB instances inside a VPC. Each VPC security group rule enables a specific source to access a DB instance in a VPC that is associated with that VPC security group. The source can be a range of addresses (for example, 203.0.113.0/24), or another VPC security group. By specifying a VPC security group as the source, you allow incoming traffic from all instances (typically application servers) that use the source VPC security group.

Before attempting to connect to your DB instance, configure your VPC for your use case. The following are common scenarios for accessing a DB instance in a VPC:

- **A DB instance in a VPC accessed by an Amazon EC2 instance in the same VPC** – A common use of a DB instance in a VPC is to share data with an application server that is running in an EC2 instance in the same VPC. The EC2 instance might run a web server with an application that interacts with the DB instance.
- **A DB instance in a VPC accessed by an EC2 instance in a different VPC** – When your DB instance is in a different VPC from the EC2 instance that you're using to access it, you can use VPC peering to access the DB instance.
- **A DB instance in a VPC accessed by a client application through the internet** – To access a DB instance in a VPC from a client application through the internet, you configure a VPC with a single public subnet, and an internet gateway to enable communication over the internet.

To connect to a DB instance from outside of its VPC, the DB instance must be publicly accessible. Also, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see [Can't connect to Amazon RDS DB instance \(p. 1746\)](#).

- **A DB instance in a VPC accessed by a private network** – If your DB instance isn't publicly accessible, you can use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network.
- **A DB instance in a VPC accessed by an EC2 instance not in a VPC** – You can communicate between a DB instance that is in a VPC and an EC2 instance that is not in a VPC by using ClassicLink.

For more information, see [Scenarios for accessing a DB instance in a VPC \(p. 1720\)](#).

Connecting to a DB instance that is running a specific DB engine

For information about connecting to a DB instance that is running a specific DB engine, follow the instructions for your DB engine:

- [Connecting to a DB instance running the MariaDB database engine \(p. 588\)](#)
- [Connecting to a DB instance running the Microsoft SQL Server database engine \(p. 656\)](#)
- [Connecting to a DB instance running the MySQL database engine \(p. 840\)](#)

- [Connecting to your Oracle DB instance \(p. 1001\)](#)
- [Connecting to a DB instance running the PostgreSQL database engine \(p. 1508\)](#)

Managing connections with RDS Proxy

You can also use Amazon RDS Proxy to manage connections to MySQL and PostgreSQL DB instances. RDS Proxy allows applications to pool and share database connections to improve scalability.

- [Managing connections with Amazon RDS Proxy \(p. 167\)](#)

Managing connections with Amazon RDS Proxy

By using Amazon RDS Proxy, you can allow your applications to pool and share database connections to improve their ability to scale. RDS Proxy makes applications more resilient to database failures by automatically connecting to a standby DB instance while preserving application connections. RDS Proxy also enables you to enforce AWS Identity and Access Management (IAM) authentication for databases, and securely store credentials in AWS Secrets Manager.

Note

RDS Proxy is fully compatible with MySQL and PostgreSQL. You can enable RDS Proxy for most applications with no code changes.

Using RDS Proxy, you can handle unpredictable surges in database traffic that otherwise might cause issues due to oversubscribing connections or creating new connections at a fast rate. RDS Proxy establishes a database connection pool and reuses connections in this pool without the memory and CPU overhead of opening a new database connection each time. To protect the database against oversubscription, you can control the number of database connections that are created.

RDS Proxy queues or throttles application connections that can't be served immediately from the pool of connections. Although latencies might increase, your application can continue to scale without abruptly failing or overwhelming the database. If connection requests exceed the limits you specify, RDS Proxy rejects application connections (that is, it sheds load). At the same time, it maintains predictable performance for the load that can be served with the available capacity.

You can reduce the overhead to process credentials and establish a secure connection for each new connection. RDS Proxy can handle some of that work on behalf of the database.

RDS Proxy concepts and terminology

You can simplify connection management for your Amazon RDS DB instances and Amazon Aurora DB clusters by using RDS Proxy.

RDS Proxy handles the network traffic between the client application and the database. It does so in an active way first by understanding the database protocol. It then adjusts its behavior based on the SQL operations from your application and the result sets from the database.

RDS Proxy reduces the memory and CPU overhead for connection management on your database. The database needs less memory and CPU resources when applications open many simultaneous connections. It also doesn't require logic in your applications to close and reopen connections that stay idle for a long time. Similarly, it requires less application logic to reestablish connections in case of a database problem.

The infrastructure for RDS Proxy is highly available and deployed over multiple Availability Zones (AZs). The computation, memory, and storage for RDS Proxy are independent of your RDS DB instances and Aurora DB clusters. This separation helps lower overhead on your database servers, so that they can devote their resources to serving database workloads. The RDS Proxy compute resources are serverless, automatically scaling based on your database workload.

Topics

- [Overview of RDS Proxy concepts \(p. 168\)](#)
- [Connection pooling \(p. 169\)](#)
- [RDS Proxy security \(p. 169\)](#)
- [Failover \(p. 170\)](#)
- [Transactions \(p. 171\)](#)

Overview of RDS Proxy concepts

RDS Proxy handles the infrastructure to perform connection pooling and the other features described following. You see the proxies represented in the RDS console on the [Proxies](#) page.

Each proxy handles connections to a single RDS DB instance or Aurora DB cluster. The proxy automatically determines the current writer instance for RDS Multi-AZ DB instances and Aurora provisioned clusters. For Aurora multi-master clusters, the proxy connects to one of the writer instances and uses the other writer instances as hot standby targets.

The connections that a proxy keeps open and available for your database application to use make up the *connection pool*.

By default, RDS Proxy can reuse a connection after each transaction in your session. This transaction-level reuse is called *multiplexing*. When RDS Proxy temporarily removes a connection from the connection pool to reuse it, that operation is called *borrowing* the connection. When it's safe to do so, RDS Proxy returns that connection to the connection pool.

In some cases, RDS Proxy can't be sure that it's safe to reuse a database connection outside of the current session. In these cases, it keeps the session on the same connection until the session ends. This fallback behavior is called *pinning*.

A proxy has a default endpoint. You connect to this endpoint when you work with an RDS DB instance or Aurora DB cluster, instead of connecting to the read/write endpoint that connects directly to the instance or cluster. The special-purpose endpoints for an Aurora cluster remain available for you to use. For Aurora DB clusters, you can also create additional read/write and read-only endpoints. For more information, see [Overview of proxy endpoints \(p. 197\)](#).

For example, you can still connect to the cluster endpoint for read/write connections without connection pooling. You can still connect to the reader endpoint for load-balanced read-only connections. You can still connect to the instance endpoints for diagnosis and troubleshooting of specific DB instances within an Aurora cluster. If you are using other AWS services such as AWS Lambda to connect to RDS databases, you change their connection settings to use the proxy endpoint. For example, you specify the proxy endpoint to allow Lambda functions to access your database while taking advantage of RDS Proxy functionality.

Each proxy contains a target group. This *target group* embodies the RDS DB instance or Aurora DB cluster that the proxy can connect to. For an Aurora cluster, by default the target group is associated with all the DB instances in that cluster. That way, the proxy can connect to whichever Aurora DB instance is promoted to be the writer instance in the cluster. The RDS DB instance associated with a proxy, or the Aurora DB cluster and its instances, are called the *targets* of that proxy. For convenience, when you create a proxy through the console, RDS Proxy also creates the corresponding target group and registers the associated targets automatically.

An *engine family* is a related set of database engines that use the same DB protocol. You choose the engine family for each proxy that you create.

Connection pooling

Each proxy performs connection pooling for the writer instance of its associated RDS or Aurora database. *Connection pooling* is an optimization that reduces the overhead associated with opening and closing connections and with keeping many connections open simultaneously. This overhead includes memory needed to handle each new connection. It also involves CPU overhead to close each connection and open a new one, such as Transport Layer Security/Secure Sockets Layer (TLS/SSL) handshaking, authentication, negotiating capabilities, and so on. Connection pooling simplifies your application logic. You don't need to write application code to minimize the number of simultaneous open connections.

Each proxy also performs connection multiplexing, also known as connection reuse. With *multiplexing*, RDS Proxy performs all the operations for a transaction using one underlying database connection, then can use a different connection for the next transaction. You can open many simultaneous connections to the proxy, and the proxy keeps a smaller number of connections open to the DB instance or cluster. Doing so further minimizes the memory overhead for connections on the database server. This technique also reduces the chance of "too many connections" errors.

RDS Proxy security

RDS Proxy uses the existing RDS security mechanisms such as TLS/SSL and AWS Identity and Access Management (IAM). For general information about those security features, see [Security in Amazon RDS \(p. 1627\)](#). If you aren't familiar with how RDS and Aurora work with authentication, authorization, and other areas of security, make sure to familiarize yourself with how RDS and Aurora work with those areas first.

RDS Proxy can act as an additional layer of security between client applications and the underlying database. For example, you can connect to the proxy using TLS 1.2, even if the underlying DB instance supports only TLS 1.0 or 1.1. You can connect to the proxy using an IAM role, even if the proxy connects to the database using the native user and password authentication method. By using this technique, you can enforce strong authentication requirements for database applications without a costly migration effort for the DB instances themselves.

You store the database credentials used by RDS Proxy in AWS Secrets Manager. Each database user for the RDS DB instance or Aurora DB cluster accessed by a proxy must have a corresponding secret in Secrets Manager. You can also set up IAM authentication for users of RDS Proxy. By doing so, you can enforce IAM authentication for database access even if the databases use native password authentication. We recommend using these security features instead of embedding database credentials in your application code.

Using TLS/SSL with RDS Proxy

You can connect to RDS Proxy using the TLS/SSL protocol.

Note

RDS Proxy uses certificates from the AWS Certificate Manager (ACM). If you use RDS Proxy, when you rotate your TLS/SSL certificate you don't need to update applications that use RDS Proxy connections.

To enforce TLS for all connections between the proxy and your database, you can specify a setting **Require Transport Layer Security** when you create or modify a proxy.

RDS Proxy can also ensure that your session uses TLS/SSL between your client and the RDS Proxy endpoint. To have RDS Proxy do so, specify the requirement on the client side. SSL session variables are not set for SSL connections to a database using RDS Proxy.

- For RDS for MySQL and Aurora MySQL, specify the requirement on the client side with the `--ssl-mode` parameter when you run the `mysql` command.
- For Amazon RDS PostgreSQL and Aurora PostgreSQL, specify `sslmode=require` as part of the `conninfo` string when you run the `psql` command.

RDS Proxy supports TLS protocol version 1.0, 1.1, and 1.2. You can connect to the proxy using a higher version of TLS than you use in the underlying database.

By default, client programs establish an encrypted connection with RDS Proxy, with further control available through the `--ssl-mode` option. From the client side, RDS Proxy supports all SSL modes.

For the client, the SSL modes are the following:

PREFERRED

SSL is the first choice, but it isn't required.

DISABLED

No SSL is allowed.

REQUIRED

Enforce SSL.

VERIFY_CA

Enforce SSL and verify the certificate authority (CA).

VERIFY_IDENTITY

Enforce SSL and verify the CA and CA hostname.

Note

You can use the SSL mode `VERIFY_IDENTITY` when connecting to the default proxy endpoint. You can't use that SSL mode when you connect to proxy endpoints that you create.

When using a client with `--ssl-mode VERIFY_CA` or `VERIFY_IDENTITY`, specify the `--ssl-ca` option pointing to a CA in `.pem` format. For a `.pem` file that you can use, download the [Amazon root CA 1 trust store](#) from Amazon Trust Services.

RDS Proxy uses wildcard certificates, which apply to both a domain and its subdomains. If you use the `mysql` client to connect with SSL mode `VERIFY_IDENTITY`, currently you must use the MySQL 8.0-compatible `mysql` command.

Failover

Failover is a high-availability feature that replaces a database instance with another one when the original instance becomes unavailable. A failover might happen because of a problem with a database instance. It might also be part of normal maintenance procedures, such as during a database upgrade. Failover applies to RDS DB instances in a Multi-AZ configuration, and Aurora DB clusters with one or more reader instances in addition to the writer instance.

Connecting through a proxy makes your application more resilient to database failovers. When the original DB instance becomes unavailable, RDS Proxy connects to the standby database without dropping idle application connections. Doing so helps to speed up and simplify the failover process. The result is faster failover that's less disruptive to your application than a typical reboot or database problem.

Without RDS Proxy, a failover involves a brief outage. During the outage, you can't perform write operations on that database. Any existing database connections are disrupted and your application must reopen them. The database becomes available for new connections and write operations when a read-only DB instance is promoted to take the place of the one that's unavailable.

During DB failovers, RDS Proxy continues to accept connections at the same IP address and automatically directs connections to the new primary DB instance. Clients connecting through RDS Proxy are not susceptible to the following:

- Domain Name System (DNS) propagation delays on failover.
- Local DNS caching.
- Connection timeouts.
- Uncertainty about which DB instance is the current writer.
- Waiting for a query response from a former writer that became unavailable without closing connections.

For applications that maintain their own connection pool, going through RDS Proxy means that most connections stay alive during failovers or other disruptions. Only connections that are in the middle of a transaction or SQL statement are canceled. RDS Proxy immediately accepts new connections. When the database writer is unavailable, RDS Proxy queues up incoming requests.

For applications that don't maintain their own connection pools, RDS Proxy offers faster connection rates and more open connections. It offloads the expensive overhead of frequent reconnects from the database. It does so by reusing database connections maintained in the RDS Proxy connection pool. This approach is particularly important for TLS connections, where setup costs are significant.

Transactions

All the statements within a single transaction always use the same underlying database connection. The connection becomes available for use by a different session when the transaction ends. Using the transaction as the unit of granularity has the following consequences:

- Connection reuse can happen after each individual statement when the RDS for MySQL or Aurora MySQL `autocommit` setting is enabled.
- Conversely, when the `autocommit` setting is disabled, the first statement you issue in a session begins a new transaction. Thus, if you enter a sequence of `SELECT`, `INSERT`, `UPDATE`, and other data manipulation language (DML) statements, connection reuse doesn't happen until you issue a `COMMIT`, `ROLLBACK`, or otherwise end the transaction.
- Entering a data definition language (DDL) statement causes the transaction to end after that statement completes.

RDS Proxy detects when a transaction ends through the network protocol used by the database client application. Transaction detection doesn't rely on keywords such as `COMMIT` or `ROLLBACK` appearing in the text of the SQL statement.

In some cases, RDS Proxy might detect a database request that makes it impractical to move your session to a different connection. In these cases, it turns off multiplexing for that connection the remainder of your session. The same rule applies if RDS Proxy can't be certain that multiplexing is practical for the session. This operation is called *pinning*. For ways to detect and minimize pinning, see [Avoiding pinning \(p. 190\)](#).

Planning for and setting up RDS Proxy

In the following sections, you can find how to set up RDS Proxy. You can also find how to set the related security options that control who can access each proxy and how each proxy connects to DB instances.

Topics

- [Limits for RDS Proxy \(p. 172\)](#)
- [Identifying DB instances, clusters, and applications to use with RDS Proxy \(p. 173\)](#)
- [Setting up network prerequisites \(p. 174\)](#)
- [Setting up database credentials in AWS Secrets Manager \(p. 175\)](#)
- [Setting up AWS Identity and Access Management \(IAM\) policies \(p. 176\)](#)
- [Creating an RDS Proxy \(p. 178\)](#)
- [Viewing an RDS Proxy \(p. 181\)](#)

Limits for RDS Proxy

The following limitations apply to RDS Proxy:

- RDS Proxy is available only in certain AWS Regions only. For more information, see [Amazon RDS Proxy](#).
You can have up to 20 proxies for each AWS account ID. If your application requires more proxies, you can request additional proxies by opening a ticket with the AWS Support organization.
- Each proxy can have up to 200 associated Secrets Manager secrets. Thus, each proxy can connect to up to 200 different user accounts at any given time.
- You can create, view, modify, and delete up to 20 endpoints for each proxy. These endpoints are in addition to the default endpoint that's automatically created for each proxy.
- In an Aurora cluster, all of the connections using the default proxy endpoint are handled by the Aurora writer instance. To perform load balancing for read-intensive workloads, you can create a read-only endpoint for a proxy. That endpoint passes connections to the reader endpoint of the cluster. That way, your proxy connections can take advantage of Aurora read scalability. For more information, see [Overview of proxy endpoints \(p. 197\)](#).

For RDS DB instances in replication configurations, you can associate a proxy only with the writer DB instance, not a read replica.

- You can't use RDS Proxy with Aurora Serverless clusters.
- You can't use RDS Proxy with Aurora clusters that are part of an Aurora global database.
- Your RDS Proxy must be in the same VPC as the database. The proxy can't be publicly accessible, although the database can be.

Note

For Aurora DB clusters, you can enable cross-VPC access by creating an additional endpoint for a proxy and specifying a different VPC, subnets, and security groups with that endpoint. For more information, see [Accessing Aurora and RDS databases across VPCs \(p. 198\)](#).

- You can't use RDS Proxy with a VPC that has dedicated tenancy.
- If you use RDS Proxy with an RDS DB instance or Aurora DB cluster that has IAM authentication enabled, make sure that all users who connect through a proxy authenticate through user names and passwords. See [Setting up AWS Identity and Access Management \(IAM\) policies \(p. 176\)](#) for details about IAM support in RDS Proxy.
- You can't use RDS Proxy with custom DNS.
- RDS Proxy is available for the MySQL and PostgreSQL engine families.
- Each proxy can be associated with a single target DB instance or cluster. However, you can associate multiple proxies with the same DB instance or cluster.

The following RDS Proxy prerequisites and limitations apply to MySQL:

- For RDS for MySQL, RDS Proxy supports MySQL 5.6 and 5.7. For Aurora MySQL, RDS Proxy supports version 1 (compatible with MySQL 5.6) and version 2 (compatible with MySQL 5.7).

- Currently, all proxies listen on port 3306 for MySQL. The proxies still connect to your database using the port that you specified in the database settings.
- You can't use RDS Proxy with RDS for MySQL 8.0.
- You can't use RDS Proxy with self-managed MySQL databases in EC2 instances.
- Proxies don't support MySQL compressed mode. For example, they don't support the compression used by the `--compress` or `-C` options of the `mysql` command.
- Some SQL statements and functions can change the connection state without causing pinning. For the most current pinning behavior, see [Avoiding pinning \(p. 190\)](#).

The following RDS Proxy prerequisites and limitations apply to PostgreSQL:

- For RDS PostgreSQL, RDS Proxy supports version 10.10 and higher minor versions, and version 11.5 and higher minor versions. For Aurora PostgreSQL, RDS Proxy supports version 10.11 and higher minor versions, and 11.6 and higher minor versions.
- Currently, all proxies listen on port 5432 for PostgreSQL.
- Query cancellation isn't supported for PostgreSQL.
- The results of the PostgreSQL function `lastval` aren't always accurate. As a work-around, use the `INSERT` statement with the `RETURNING` clause.

Identifying DB instances, clusters, and applications to use with RDS Proxy

You can determine which of your DB instances, clusters, and applications might benefit the most from using RDS Proxy. To do so, consider these factors:

- RDS Proxy is highly available and deployed over multiple Availability Zones (AZs). To ensure overall high availability for your database, deploy your Amazon RDS DB instance or Aurora cluster in a Multi-AZ configuration.
- Any DB instance or cluster that encounters "too many connections" errors is a good candidate for associating with a proxy. The proxy enables applications to open many client connections, while the proxy manages a smaller number of long-lived connections to the DB instance or cluster.
- For DB instances or clusters that use smaller AWS instance classes, such as T2 or T3, using a proxy can help avoid out-of-memory conditions. It can also help reduce the CPU overhead for establishing connections. These conditions can occur when dealing with large numbers of connections.
- You can monitor certain Amazon CloudWatch metrics to determine whether a DB instance or cluster is approaching certain types of limit. These limits are for the number of connections and the memory associated with connection management. You can also monitor certain CloudWatch metrics to determine whether a DB instance or cluster is handling many short-lived connections. Opening and closing such connections can impose performance overhead on your database. For information about the metrics to monitor, see [Monitoring RDS Proxy using Amazon CloudWatch \(p. 192\)](#).
- AWS Lambda functions can also be good candidates for using a proxy. These functions make frequent short database connections that benefit from connection pooling offered by RDS Proxy. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.
- Applications that use languages and frameworks such as PHP and Ruby on Rails are typically good candidates for using a proxy. Such applications typically open and close large numbers of database connections, and don't have built-in connection pooling mechanisms.
- Applications that keep a large number of connections open for long periods are typically good candidates for using a proxy. Applications in industries such as software as a service (SaaS) or ecommerce often minimize the latency for database requests by leaving connections open. With RDS Proxy, an application can keep more connections open than it can when connecting directly to the DB instance or cluster.

- You might not have adopted IAM authentication and Secrets Manager due to the complexity of setting up such authentication for all DB instances and clusters. If so, you can leave the existing authentication methods in place and delegate the authentication to a proxy. The proxy can enforce the authentication policies for client connections for particular applications. You can take advantage of any IAM authentication you already have for Lambda functions, instead of managing database credentials in your Lambda application code.

Setting up network prerequisites

Using RDS Proxy requires you to have a set of networking resources in place. These include a virtual private cloud (VPC), two or more subnets, an Amazon EC2 instance within the same VPC, and an internet gateway. If you've successfully connected to any RDS DB instances or Aurora DB clusters, you already have the required network resources.

The following Linux example shows AWS CLI commands that examine the VPCs and subnets owned by your AWS account. In particular, you pass subnet IDs as parameters when you create a proxy using the CLI.

```
aws ec2 describe-vpcs
aws ec2 describe-internet-gateways
aws ec2 describe-subnets --query '*[].[VpcId,SubnetId]' --output text | sort
```

The following Linux example shows AWS CLI commands to determine the subnet IDs corresponding to a specific Aurora DB cluster or RDS DB instance. For an Aurora cluster, first you find the ID for one of the associated DB instances. You can extract the subnet IDs used by that DB instance by examining the nested fields within the `DBSubnetGroup` and `Subnets` attributes in the describe output for the DB instance. You specify some or all of those subnet IDs when setting up a proxy for that database server.

```
$ # Optional first step, only needed if you're starting from an Aurora cluster. Find the ID of any DB instance in the cluster.
$ aws rds describe-db-clusters --db-cluster-id my_cluster_id --query '*[].[DBClusterMembers|[0]|[0][*].DBInstanceIdentifier' --output text
my_instance_id
instance_id_2
instance_id_3
...

$ # From the DB instance, trace through the DBSubnetGroup and Subnets to find the subnet IDs.
$ aws rds describe-db-instances --db-instance-id my_instance_id --query '*[].[DBSubnetGroup|[0]|[0][[Subnets]|[0][*].SubnetIdentifier' --output text
subnet_id_1
subnet_id_2
subnet_id_3
...
```

As an alternative, you can first find the VPC ID for the DB instance. Then you can examine the VPC to find its subnets. The following Linux example shows how.

```
$ # From the DB instance, find the VPC.
$ aws rds describe-db-instances --db-instance-id my_instance_id --query '*[].[VpcId]' --output text
my_vpc_id

$ aws ec2 describe-subnets --filters Name=vpc-id,Values=my_vpc_id --query '*[].[SubnetId]' --output text
subnet_id_1
subnet_id_2
subnet_id_3
```

```
subnet_id_4
subnet_id_5
subnet_id_6
```

Setting up database credentials in AWS Secrets Manager

For each proxy that you create, you first use the Secrets Manager service to store sets of user name and password credentials. You create a separate Secrets Manager secret for each database user account that the proxy connects to on the RDS DB instance or Aurora DB cluster.

In Secrets Manager, you create these secrets with values for the `username` and `password` fields. Doing so allows the proxy to connect to the corresponding database users on whichever RDS DB instances or Aurora DB clusters that you associate with the proxy. To do this, you can use the setting **Credentials for other database**, **Credentials for RDS database**, or **Other type of secrets**. Fill in the appropriate values for the **User name** and **Password** fields, and placeholder values for any other required fields. The proxy ignores other fields such as **Host** and **Port** if they're present in the secret. Those details are automatically supplied by the proxy.

You can also choose **Other type of secrets**. In this case, you create the secret with keys named `username` and `password`.

Because the secrets used by your proxy aren't tied to a specific database server, you can reuse a secret across multiple proxies if you use the same credentials across multiple database servers. For example, you might use the same credentials across a group of development and test servers.

To connect through the proxy as a specific user, make sure that the password associated with a secret matches the database password for that user. If there's a mismatch, you can update the associated secret in Secrets Manager. In this case, you can still connect to other accounts where the secret credentials and the database passwords do match.

When you create a proxy through the AWS CLI or RDS API, you specify the Amazon Resource Names (ARNs) of the corresponding secrets for all the DB user accounts that the proxy can access. In the AWS Management Console, you choose the secrets by their descriptive names.

For instructions about creating secrets in Secrets Manager, see the [Creating a secret](#) page in the Secrets Manager documentation. Use one of the following techniques:

- Use [Secrets Manager](#) in the console.
- To use the CLI to create a Secrets Manager secret for use with RDS Proxy, use a command such as the following.

```
aws secretsmanager create-secret \
--name "secret_name"
--description "secret_description"
--region region_name
--secret-string '{"username":"db_user","password":"db_user_password"}'
```

For example, the following commands create Secrets Manager secrets for two database users, one named `admin` and the other named `app-user`.

```
aws secretsmanager create-secret \
--name admin_secret_name --description "db admin user" \
--secret-string '{"username":"admin","password":"choose_your_own_password"}'

aws secretsmanager create-secret \
--name proxy_secret_name --description "application user" \
--secret-string '{"username":"app-user","password":"choose_your_own_password"}'
```

To see the secrets owned by your AWS account, use a command such as the following.

```
aws secretsmanager list-secrets
```

When you create a proxy using the CLI, you pass the Amazon resource names (ARNs) of one or more secrets to the `--auth` parameter. The following Linux example shows how to prepare a report with only the name and ARN of each secret owned by your AWS account. This example uses the `--output table` parameter that is available in AWS CLI version 2. If you are using AWS CLI version 1, use `--output text` instead.

```
aws secretsmanager list-secrets --query '*[].[Name,ARN]' --output table
```

To verify that you stored the correct credentials and in the right format in a secret, use a command such as the following. Substitute the short name or the ARN of the secret for `your_secret_name`.

```
aws secretsmanager get-secret-value --secret-id your_secret_name
```

The output should include a line displaying a JSON-encoded value like the following.

```
"SecretString": "{\"username\":\"your_username\", \"password\":\"your_password\"}"}
```

Setting up AWS Identity and Access Management (IAM) policies

After you create the secrets in Secrets Manager, you create an IAM policy that can access those secrets. For general information about using IAM with RDS and Aurora, see [Identity and access management in Amazon RDS \(p. 1644\)](#).

Tip

The following procedure applies if you use the IAM console. If you use the AWS Management Console for RDS, RDS can create the IAM policy for you automatically. In that case, you can skip the following procedure.

To create an IAM policy that accesses your Secrets Manager secrets for use with your proxy

1. Sign in to the IAM console. Follow the **Create role** process, as described in [Creating IAM roles](#). Include the **Add Role to Database** step.
 2. For the new role, perform the **Add inline policy** step. Use the same general procedures as in [Editing IAM policies](#). Paste the following JSON into the JSON text box. Substitute your own account ID. Substitute your AWS Region for us-east-2. Substitute the Amazon Resource Names (ARNs) for the secrets that you created. For the kms : Decrypt action, substitute the ARN of the default AWS KMS customer master key (CMK) or your own AWS KMS CMK, depending on which one you used to encrypt the Secrets Manager secrets.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Sid": "VisualEditor0",  
            "Effect": "Allow",  
            "Action": "secretsmanager:GetSecretValue",  
            "Resource": [  
                "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_1",  
                "arn:aws:secretsmanager:us-east-2:account_id:secret:secret_name_2"  
            ]  
        },  
        {  
            "Sid": "VisualEditor1",  
            "Effect": "Allow",  
            "Action": "kms:Decrypt",  
            "Resource": "arn:aws:kms:us-east-2:account_id:key/key_id".  
    ]  
}
```

```
        "Condition": {
            "StringEquals": {
                "kms:ViaService": "secretsmanager.us-east-2.amazonaws.com"
            }
        }
    ]
}
```

3. Edit the trust policy for this IAM role. Paste the following JSON into the JSON text box.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

The following commands perform the same operation through the AWS CLI.

```
PREFIX=choose_an_identifier

aws iam create-role --role-name choose_role_name \
--assume-role-policy-document '{"Version":"2012-10-17","Statement":\
[{"Effect":"Allow","Principal": {"Service":\
["rds.amazonaws.com"]}, "Action": "sts:AssumeRole"}]}'"

aws iam put-role-policy --role-name same_role_name_as_previous \
--policy-name $PREFIX-secret-reader-policy --policy-document """
same_json_as_in_previous_example
"""

aws kms create-key --description "$PREFIX-test-key" --policy """
{
    "Id": "$PREFIX-kms-policy",
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Enable IAM User Permissions",
            "Effect": "Allow",
            "Principal": {"AWS": "arn:aws:iam::account_id:root"},
            "Action": "kms:*", "Resource": "*"
        },
        {
            "Sid": "Allow access for Key Administrators",
            "Effect": "Allow",
            "Principal": {
                "AWS": [
                    "$USER_ARN", "arn:aws:iam::account_id:role/Admin"
                ],
                "Action": [
                    "kms>Create*",
                    "kms:Describe*",

```

```

"""
}
```

Creating an RDS Proxy

To manage connections for a specified set of DB instances, you can create a proxy. You can associate a proxy with an RDS for MySQL DB instance, PostgreSQL DB instance, or an Aurora DB cluster.

AWS Management Console

To create a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. Choose **Create proxy**.
4. Choose all the settings for your proxy.

For **Proxy configuration**, provide information for the following:

- **Proxy identifier.** Specify a name of your choosing, unique within your AWS account ID and current AWS Region.
- **Engine compatibility.** Choose either **MySQL** or **POSTGRESQL**.
- **Require Transport Layer Security.** Choose this setting if you want the proxy to enforce TLS/SSL for all client connections. When you use an encrypted or unencrypted connection to a proxy, the proxy uses the same encryption setting when it makes a connection to the underlying database.
- **Idle client connection timeout.** Choose a time period that a client connection can be idle before the proxy can close it. The default is 1,800 seconds (30 minutes). A client connection is considered idle when the application doesn't submit a new request within the specified time after the previous request completed. The underlying database connection stays open and is returned to the connection pool. Thus, it's available to be reused for new client connections.

Consider lowering the idle client connection timeout if you want the proxy to proactively remove stale connections. If your workload is spiking, consider raising the idle client connection timeout to save the cost of establishing connections.

For **Target group configuration**, provide information for the following:

- **Database.** Choose one RDS DB instance or Aurora DB cluster to access through this proxy. The list only includes DB instances and clusters with compatible database engines, engine versions, and other settings. If the list is empty, create a new DB instance or cluster that's compatible with RDS Proxy. To do so, follow the procedure in [Creating an Amazon RDS DB instance \(p. 141\)](#). Then try creating the proxy again.
- **Connection pool maximum connections.** Specify a value from 1 through 100. This setting represents the percentage of the `max_connections` value that RDS Proxy can use for its connections. If you only intend to use one proxy with this DB instance or cluster, you can set this value to 100. For details about how RDS Proxy uses this setting, see [Controlling connection limits and timeouts \(p. 189\)](#).
- **Session pinning filters.** (Optional) This is an advanced setting, for troubleshooting performance issues with particular applications. Currently, the only choice is `EXCLUDE_VARIABLE_SETS`. Choose a filter only if both of following are true: Your application isn't reusing connections due to certain kinds of SQL statements, and you can verify that reusing connections with those SQL statements doesn't affect application correctness. For more information, see [Avoiding pinning \(p. 190\)](#).
- **Connection borrow timeout.** In some cases, you might expect the proxy to sometimes use all available database connections. In such cases, you can specify how long the proxy waits for a database connection to become available before returning a timeout error. You can specify a period up to a maximum of five minutes. This setting only applies when the proxy has the maximum number of connections open and all connections are already in use.

For **Connectivity**, provide information for the following:

- **Secrets Manager ARNs.** Choose at least one Secrets Manager secret that contains DB user credentials for the RDS DB instance or Aurora DB cluster that you intend to access with this proxy.
- **IAM role.** Choose an IAM role that has permission to access the Secrets Manager secrets that you chose earlier. You can also choose for the AWS Management Console to create a new IAM role for you and use that.
- **IAM Authentication.** Choose whether to require or disallow IAM authentication for connections to your proxy. The choice of IAM authentication or native database authentication applies to all DB users that access this proxy.
- **Subnets.** This field is prepopulated with all the subnets associated with your VPC. You can remove any subnets that you don't need for this proxy. You must leave at least two subnets.

Provide additional connectivity configuration:

- **VPC security group.** Choose an existing VPC security group. You can also choose for the AWS Management Console to create a new security group for you and use that.

Note

This security group must allow access to the database the proxy connects to. The same security group is used for ingress from your applications to the proxy, and for egress from the proxy to the database. For example, suppose that you use the same security group for your database and your proxy. In this case, make sure that you specify that resources in that security group can communicate with other resources in the same security group.

(Optional) Provide advanced configuration:

- **Enable enhanced logging.** You can enable this setting to troubleshoot proxy compatibility or performance issues.

When this setting is enabled, RDS Proxy includes detailed information about SQL statements in its logs. This information helps you to debug issues involving SQL behavior or the performance and scalability of the proxy connections. The debug information includes the text of SQL statements that you submit through the proxy. Thus, only enable this setting when needed for debugging, and only when you have security measures in place to safeguard any sensitive information that appears in the logs.

To minimize overhead associated with your proxy, RDS Proxy automatically turns this setting off 24 hours after you enable it. Enable it temporarily to troubleshoot a specific issue.

5. Choose **Create Proxy**.

AWS CLI

To create a proxy, use the AWS CLI command [create-db-proxy](#). The --engine-family value is case-sensitive.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-proxy \
--db-proxy-name proxy_name \
--engine-family { MYSQL | POSTGRESOL } \
--auth ProxyAuthenticationConfig_JSON_string \
--role-arn iam_role \
--vpc-subnet-ids space_separated_list \
[--vpc-security-group-ids space_separated_list] \
[--require-tls | --no-require-tls] \
[--idle-client-timeout value] \
[--debug-logging | --no-debug-logging] \
[--tags comma_separated_list]
```

For Windows:

```
aws rds create-db-proxy ^
--db-proxy-name proxy_name ^
--engine-family { MYSQL | POSTGRESOL } ^
--auth ProxyAuthenticationConfig_JSON_string ^
--role-arn iam_role ^
--vpc-subnet-ids space_separated_list ^
[--vpc-security-group-ids space_separated_list] ^
[--require-tls | --no-require-tls] ^
[--idle-client-timeout value] ^
[--debug-logging | --no-debug-logging] ^
[--tags comma_separated_list]
```

Tip

If you don't already know the subnet IDs to use for the --vpc-subnet-ids parameter, see [Setting up network prerequisites \(p. 174\)](#) for examples of how to find the subnet IDs that you can use.

To create the required information and associations for the proxy, you also use the [register-db-proxy-targets](#) command. Specify the target group name default. RDS Proxy automatically creates a target group with this name when you create each proxy.

```
aws rds register-db-proxy-targets
--db-proxy-name value
```

```
[--target-group-name target_group_name]
[--db-instance-identifiers space_separated_list] # rds db instances, or
[--db-cluster-identifiers cluster_id]           # rds db cluster (all instances), or
[--db-cluster-endpoint endpoint_name]          # rds db cluster endpoint (all
instances)
```

RDS API

To create an RDS proxy, call the Amazon RDS API operation [CreateDBProxy](#). You pass a parameter with the [AuthConfig](#) data structure.

RDS Proxy automatically creates a target group named `default` when you create each proxy. You associate an RDS DB instance or Aurora DB cluster with the target group by calling the function [RegisterDBProxyTargets](#).

Viewing an RDS Proxy

After you create one or more RDS proxies, you can view them all to examine their configuration details and choose which ones to modify, delete, and so on.

Any database applications that use the proxy require the proxy endpoint to use in the connection string.

AWS Management Console

To view your proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the AWS Management Console, choose the AWS Region in which you created the RDS Proxy.
3. In the navigation pane, choose **Proxies**.
4. Choose the name of an RDS proxy to display its details.
5. On the details page, the **Target groups** section shows how the proxy is associated with a specific RDS DB instance or Aurora DB cluster. You can follow the link to the **default** target group page to see more details about the association between the proxy and the database. This page is where you see settings that you specified when creating the proxy, such as maximum connection percentage, connection borrow timeout, engine compatibility, and session pinning filters.

CLI

To view your proxy using the CLI, use the [describe-db-proxies](#) command. By default, it displays all proxies owned by your AWS account. To see details for a single proxy, specify its name with the `--db-proxy-name` parameter.

```
aws rds describe-db-proxies [--db-proxy-name proxy_name]
```

To view the other information associated with the proxy, use the following commands.

```
aws rds describe-db-proxy-target-groups --db-proxy-name proxy_name
aws rds describe-db-proxy-targets --db-proxy-name proxy_name
```

Use the following sequence of commands to see more detail about the things that are associated with the proxy:

1. To get a list of proxies, run [describe-db-proxies](#).

2. To show connection parameters such as the maximum percentage of connections that the proxy can use, run `describe-db-proxy-target-groups` --db-proxy-name and use the name of the proxy as the parameter value.
3. To see the details of the RDS DB instance or Aurora DB cluster associated with the returned target group, run `describe-db-proxy-targets`.

RDS API

To view your proxies using the RDS API, use the `DescribeDBProxies` operation. It returns values of the `DBProxy` data type.

To see details of the connection settings for the proxy, use the proxy identifiers from this return value with the `DescribeDBProxyTargetGroups` operation. It returns values of the `DBProxyTargetGroup` data type.

To see the RDS instance or Aurora DB cluster associated with the proxy, use the `DescribeDBProxyTargets` operation. It returns values of the `DBProxyTarget` data type.

Connecting to a database through RDS Proxy

You connect to an RDS DB instance or Aurora DB cluster through a proxy in generally the same way as you connect directly to the database. The main difference is that you specify the proxy endpoint instead of the instance or cluster endpoint. For an Aurora DB cluster, by default all proxy connections have read/write capability and use the writer instance. If you normally use the reader endpoint for read-only connections, you can create an additional read-only endpoint for the proxy and use that endpoint the same way. For more information, see [Overview of proxy endpoints \(p. 197\)](#).

Topics

- [Connecting to a proxy using native authentication \(p. 182\)](#)
- [Connecting to a proxy using IAM authentication \(p. 183\)](#)
- [Considerations for connecting to a proxy with PostgreSQL \(p. 183\)](#)

Connecting to a proxy using native authentication

Use the following basic steps to connect to a proxy using native authentication:

1. Find the proxy endpoint. In the AWS Management Console, you can find the endpoint on the details page for the corresponding proxy. With the AWS CLI, you can use the `describe-db-proxies` command. The following example shows how.

```
# Add --output text to get output as a simple tab-separated list.
$ aws rds describe-db-proxies --query '*[*].{DBProxyName:DBProxyName,Endpoint:Endpoint}'
[
    [
        {
            "Endpoint": "the-proxy.proxy-demo.us-east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy"
        },
        {
            "Endpoint": "the-proxy-other-secret.proxy-demo.us-east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy-other-secret"
        },
        {
            "Endpoint": "the-proxy-rds-secret.proxy-demo.us-east-1.rds.amazonaws.com",
            "DBProxyName": "the-proxy-rds-secret"
        }
    ]
]
```

```
        "Endpoint": "the-proxy-t3.proxy-demo.us-east-1.rds.amazonaws.com",
        "DBProxyName": "the-proxy-t3"
    }
]
```

2. Specify that endpoint as the host parameter in the connection string for your client application. For example, specify the proxy endpoint as the value for the `mysql -h` option or `psql -h` option.
3. Supply the same database user name and password as you usually do.

Connecting to a proxy using IAM authentication

When you use IAM authentication with RDS Proxy, set up your database users to authenticate with regular user names and passwords. The IAM authentication applies to RDS Proxy retrieving the user name and password credentials from Secrets Manager. The connection from RDS Proxy to the underlying database doesn't go through IAM.

To connect to RDS Proxy using IAM authentication, follow the same general procedure as for connecting to an RDS DB instance or Aurora cluster using IAM authentication. For general information about using IAM with RDS and Aurora, see [Security in Amazon RDS \(p. 1627\)](#).

The major differences in IAM usage for RDS Proxy include the following:

- You don't configure each individual database user with an authorization plugin. The database users still have regular user names and passwords within the database. You set up Secrets Manager secrets containing these user names and passwords, and authorize RDS Proxy to retrieve the credentials from Secrets Manager.

Important

The IAM authentication applies to the connection between your client program and the proxy. The proxy then authenticates to the database using the user name and password credentials retrieved from Secrets Manager. When you use IAM for the connection to a proxy, make sure that the underlying RDS DB instance or Aurora DB cluster doesn't have IAM enabled.

- Instead of the instance, cluster, or reader endpoint, you specify the proxy endpoint. For details about the proxy endpoint, see [Connecting to your DB instance using IAM authentication \(p. 1668\)](#).
- In the direct DB IAM auth case, you selectively pick database users and configure them to be identified with a special auth plugin. You can then connect to those users using IAM auth.

In the proxy use case, you need to provide the proxy with Secrets that contain some user's username and password (native auth). You then connect to the proxy using IAM auth (by generating an auth token with the proxy endpoint, not the database endpoint) and using a username which matches one of the usernames for the secrets you previously provided.

- Make sure that you use Transport Layer Security (TLS) / Secure Sockets Layer (SSL) when connecting to a proxy using IAM authentication.

You can grant a specific user access to the proxy by modifying the IAM policy. An example follows.

```
"Resource": "arn:aws:rds-db:us-east-2:1234567890:dbuser:prx-ABCDEFGHIJKLM01234/db_user"
```

Considerations for connecting to a proxy with PostgreSQL

For PostgreSQL, when a client starts a connection to a PostgreSQL database, it sends a startup message that includes pairs of parameter name and value strings. For details, see the `StartupMessage` in [PostgreSQL message formats](#) in the PostgreSQL documentation.

When connecting through an RDS proxy, the startup message can include the following currently recognized parameters:

- `user`
- `database`
- `replication`

The startup message can also include the following additional runtime parameters:

- `application_name`
- `client_encoding`
- `DateStyle`
- `TimeZone`
- `extra_float_digits`

For more information about PostgreSQL messaging, see the [Frontend/Backend protocol](#) in the PostgreSQL documentation.

For PostgreSQL, if you use JDBC we recommend the following to avoid pinning:

- Set the JDBC connection parameter `assumeMinServerVersion` to at least `9.0` to avoid pinning. Doing this prevents the JDBC driver from performing an extra round trip during connection startup when it runs `SET extra_float_digits = 3`.
- Set the JDBC connection parameter `ApplicationName` to `any/your-application-name` to avoid pinning. Doing this prevents the JDBC driver from performing an extra round trip during connection startup when it runs `SET application_name = "PostgreSQL JDBC Driver"`. Note the JDBC parameter is `ApplicationName` but the PostgreSQL `StartupMessage` parameter is `application_name`.
- Set the JDBC connection parameter `preferQueryMode` to `extendedForPrepared` to avoid pinning. The `extendedForPrepared` ensures that the extended mode is used only for prepared statements.

The default for the `preferQueryMode` parameter is `extended`, which uses the extended mode for all queries. The extended mode uses a series of `Prepare`, `Bind`, `Execute`, and `Sync` requests and corresponding responses. This type of series causes connection pinning in an RDS proxy.

For more information, see [Avoiding pinning \(p. 190\)](#). For more information about connecting using JDBC, see [Connecting to the database](#) in the PostgreSQL documentation.

Managing an RDS Proxy

Following, you can find an explanation of how to manage RDS proxy operation and configuration. These procedures help your application make the most efficient use of database connections and achieve maximum connection reuse. The more that you can take advantage of connection reuse, the more CPU and memory overhead that you can save. This in turn reduces latency for your application and enables the database to devote more of its resources to processing application requests.

Modifying an RDS Proxy

You can change certain settings associated with a proxy after you create the proxy. You do so by modifying the proxy itself, its associated target group, or both. Each proxy has an associated target group.

AWS Management Console

To modify the settings for a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. In the list of proxies, choose the proxy whose settings you want to modify or go to its details page.
4. For **Actions**, choose **Modify**.
5. Enter or choose the properties to modify. You can do the following:
 - Rename the proxy by entering a new identifier.
 - Turn the requirement for Transport layer Security (TLS) on or off.
 - Enter a time period for the idle connection timeout.
 - Add or remove Secrets Manager secrets. These secrets correspond to database user names and passwords.
 - Change the IAM role used to retrieve the secrets from Secrets Manager.
 - Require or disallow IAM authentication for connections to the proxy.
 - Add or remove VPC subnets for the proxy to use.
 - Add or remove VPC security groups for the proxy to use.
 - Enable or disable enhanced logging.
6. Choose **Modify**.

If you didn't find the settings listed that you want to change, use the following procedure to update the target group for the proxy. The *target group* associated with a proxy controls the settings related to the physical database connections. Each proxy has one associated target group named **default**, which is created automatically along with the proxy.

You can only modify the target group from the proxy details page, not from the list on the **Proxies** page.

To modify the settings for a proxy target group

1. On the **Proxies** page, go to the details page for a proxy.
2. For **Target groups**, choose the **default** link. Currently, all proxies have a single target group named **default**.
3. On the details page for the **default** target group, choose **Modify**.
4. Choose new settings for the properties that you can modify:
 - Choose a different RDS DB instance or Aurora cluster.
 - Adjust what percentage of the maximum available connections the proxy can use.
 - Choose a session pinning filter. Doing this can help reduce performance issues due to insufficient transaction-level reuse for connections. Using this setting requires understanding of application behavior and the circumstances under which RDS Proxy pins a session to a database connection.
 - Adjust the connection borrow timeout interval. This setting applies when the maximum number of connections is already being used for the proxy. The setting determines how long the proxy waits for a connection to become available before returning a timeout error.

You can't change certain properties, such as the target group identifier and the database engine.

5. Choose **Modify target group**.

AWS CLI

To modify a proxy using the AWS CLI, use the commands [modify-db-proxy](#), [modify-db-proxy-target-group](#), [deregister-db-proxy-targets](#), and [register-db-proxy-targets](#).

With the `modify-db-proxy` command, you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.
- The security groups used by the proxy.

The following example shows how to rename an existing proxy.

```
aws rds modify-db-proxy --db-proxy-name the-proxy --new-db-proxy-name the_new_name
```

To modify connection-related settings or rename the target group, use the `modify-db-proxy-target-group` command. Currently, all proxies have a single target group named `default`. When working with this target group, you specify the name of the proxy and `default` for the name of the target group.

The following example shows how to first check the `MaxIdleConnectionsPercent` setting for a proxy and then change it, using the target group.

```
aws rds describe-db-proxy-target-groups --db-proxy-name the-proxy
{
    "TargetGroups": [
        {
            "Status": "available",
            "UpdatedDate": "2019-11-30T16:49:30.342Z",
            "ConnectionPoolConfig": {
                "MaxIdleConnectionsPercent": 50,
                "ConnectionBorrowTimeout": 120,
                "MaxConnectionsPercent": 100,
                "SessionPinningFilters": []
            },
            "TargetGroupName": "default",
            "CreatedDate": "2019-11-30T16:49:27.940Z",
            "DBProxyName": "the-proxy",
            "IsDefault": true
        }
    ]
}

aws rds modify-db-proxy-target-group --db-proxy-name the-proxy --target-group-name default
--connection-pool-config '
{ "MaxIdleConnectionsPercent": 75 }'

{
```

```

    "DBProxyTargetGroup": {
        "Status": "available",
        "UpdatedDate": "2019-12-02T04:09:50.420Z",
        "ConnectionPoolConfig": {
            "MaxIdleConnectionsPercent": 75,
            "ConnectionBorrowTimeout": 120,
            "MaxConnectionsPercent": 100,
            "SessionPinningFilters": []
        },
        "TargetGroupName": "default",
        "CreatedDate": "2019-11-30T16:49:27.940Z",
        "DBProxyName": "the-proxy",
        "IsDefault": true
    }
}

```

With the `deregister-db-proxy-targets` and `register-db-proxy-targets` commands, you change which RDS DB instance or Aurora DB cluster the proxy is associated with through its target group. Currently, each proxy can connect to one RDS DB instance or Aurora DB cluster. The target group tracks the connection details for all the RDS DB instances in a Multi-AZ configuration, or all the DB instances in an Aurora cluster.

The following example starts with a proxy that is associated with an Aurora MySQL cluster named `cluster-56-2020-02-25-1399`. The example shows how to change the proxy so that it can connect to a different cluster named `provisioned-cluster`.

When you work with an RDS DB instance, you specify the `--db-instance-identifier` option. When you work with an Aurora DB cluster, you specify the `--db-cluster-identifier` option instead.

The following example modifies an Aurora MySQL proxy. An Aurora PostgreSQL proxy has port 5432.

```

aws rds describe-db-proxy-targets --db-proxy-name the-proxy

{
    "Targets": [
        {
            "Endpoint": "instance-9814.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-9814"
        },
        {
            "Endpoint": "instance-8898.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-8898"
        },
        {
            "Endpoint": "instance-1018.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-1018"
        },
        {
            "Type": "TRACKED_CLUSTER",
            "Port": 0,
            "RdsResourceId": "cluster-56-2020-02-25-1399"
        },
        {
            "Endpoint": "instance-4330.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "instance-4330"
        }
    ]
}

```

```

        }
    }

aws rds deregister-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier
cluster-56-2020-02-25-1399

aws rds describe-db-proxy-targets --db-proxy-name the-proxy

{
    "Targets": []
}

aws rds register-db-proxy-targets --db-proxy-name the-proxy --db-cluster-identifier
provisioned-cluster

{
    "DBProxyTargets": [
        {
            "Type": "TRACKED_CLUSTER",
            "Port": 0,
            "RdsResourceId": "provisioned-cluster"
        },
        {
            "Endpoint": "gkldje.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "gkldje"
        },
        {
            "Endpoint": "provisioned-1.demo.us-east-1.rds.amazonaws.com",
            "Type": "RDS_INSTANCE",
            "Port": 3306,
            "RdsResourceId": "provisioned-1"
        }
    ]
}

```

RDS API

To modify a proxy using the RDS API, you use the operations [ModifyDBProxy](#), [ModifyDBProxyTargetGroup](#), [DeregisterDBProxyTargets](#), and [RegisterDBProxyTargets](#) operations.

With [ModifyDBProxy](#), you can change properties such as the following:

- The set of Secrets Manager secrets used by the proxy.
- Whether TLS is required.
- The idle client timeout.
- Whether to log additional information from SQL statements for debugging.
- The IAM role used to retrieve Secrets Manager secrets.
- The security groups used by the proxy.

With [ModifyDBProxyTargetGroup](#), you can modify connection-related settings or rename the target group. Currently, all proxies have a single target group named `default`. When working with this target group, you specify the name of the proxy and `default` for the name of the target group.

With [DeregisterDBProxyTargets](#) and [RegisterDBProxyTargets](#), you change which RDS DB instance or Aurora DB cluster the proxy is associated with through its target group. Currently, each proxy can connect to one RDS DB instance or Aurora DB cluster. The target group tracks the connection details for all the RDS DB instances in a Multi-AZ configuration, or all the DB instances in an Aurora cluster.

Adding a new database user

In some cases, you might add a new database user to an RDS DB instance or Aurora cluster that's associated with a proxy. If so, add or repurpose a Secrets Manager secret to store the credentials for that user. To do this, choose one of the following options:

- Create a new Secrets Manager secret, using the procedure described in [Setting up database credentials in AWS Secrets Manager \(p. 175\)](#).
- Update the IAM role to give RDS Proxy access to the new Secrets Manager secret. To do so, update the resources section of the IAM role policy.
- If the new user takes the place of an existing one, update the credentials stored in the proxy's Secrets Manager secret for the existing user.

Changing the password for a database user

In some cases, you might change the password for a database user in an RDS DB instance or Aurora cluster that's associated with a proxy. If so, update the corresponding Secrets Manager secret with the new password.

Controlling connection limits and timeouts

RDS Proxy uses the `max_connections` setting for your RDS DB instance or Aurora DB cluster. This setting represents the overall upper limit on the connections that the proxy can open at any one time. In Aurora clusters and RDS Multi-AZ configurations, the `max_connections` value that the proxy uses is the one for the Aurora primary instance or the RDS writer instance.

To set this value for your RDS DB instance or Aurora DB cluster, follow the procedures in [Working with DB parameter groups \(p. 228\)](#). These procedures demonstrate how to associate a parameter group with your database and edit the `max_connections` value in the parameter group.

The proxy setting for maximum connections represents a percentage of the `max_connections` value for the database that's associated with the proxy. If you have multiple applications all using the same database, you can effectively divide their connection quotas by using a proxy for each application with a specific percentage of `max_connections`. If you do so, ensure that the percentages add up to 100 or less for all proxies associated with the same database.

RDS Proxy periodically disconnects idle connections and returns them to the connection pool. You can adjust this timeout interval. Doing so helps your applications to deal with stale resources, especially if the application mistakenly leaves a connection open while holding important database resources.

Managing and monitoring connection pooling

As described in [Connection pooling \(p. 169\)](#), connection pooling is a crucial RDS Proxy feature. Following, you can learn how to make the most efficient use of connection pooling and transaction-level connection reuse (multiplexing).

Because the connection pool is managed by RDS Proxy, you can monitor it and adjust connection limits and timeout intervals without changing your application code.

For each proxy, you can specify an upper limit on the number of connections used by the connection pool. You specify the limit as a percentage. This percentage applies to the maximum connections configured in the database. The exact number varies depending on the DB instance size and configuration settings.

For example, suppose that you configured RDS Proxy to use 75 percent of the maximum connections for the database. For MySQL, the maximum value is defined by the `max_connections` configuration parameter. In this case, the other 25 percent of maximum connections remain available to assign to other proxies or for connections that don't go through a proxy. In some cases, the proxy might keep

less than 75 percent of the maximum connections open at a particular time. Those cases might include situations where the database doesn't have many simultaneous connections, or some connections stay idle for long periods.

The overall number of connections available for the connection pool changes as you update the `max_connections` configuration setting that applies to an RDS DB instance or an Aurora cluster.

The proxy doesn't reserve all of these connections in advance. Thus, you can specify a relatively large percentage, and those connections are only opened when the proxy becomes busy enough to need them.

You can choose how long to wait for a connection to become available for use by your application. This setting is represented by the **Connection borrow timeout** option when you create a proxy. This setting specifies how long to wait for a connection to become available in the connection pool before returning a timeout error. It applies when the number of connections is at the maximum, and so no connections are available in the connection pool. It also applies if no writer instance is available because a failover operation is in process. Using this setting, you can set the best wait period for your application without having to change the query timeout in your application code.

Avoiding pinning

Multiplexing is more efficient when database requests don't rely on state information from previous requests. In that case, RDS Proxy can reuse a connection at the conclusion of each transaction. Examples of such state information include most variables and configuration parameters that you can change through `SET` or `SELECT` statements. SQL transactions on a client connection can multiplex between underlying database connections by default.

Your connections to the proxy can enter a state known as *pinning*. When a connection is pinned, each later transaction uses the same underlying database connection until the session ends. Other client connections also can't reuse that database connection until the session ends. The session ends when the client connection is dropped.

RDS Proxy automatically pins a client connection to a specific DB connection when it detects a session state change that isn't appropriate for other sessions. Pinning reduces the effectiveness of connection reuse. If all or almost all of your connections experience pinning, consider modifying your application code or workload to reduce the conditions that cause the pinning.

For example, if your application changes a session variable or configuration parameter, later statements can rely on the new variable or parameter to be in effect. Thus, when RDS Proxy processes requests to change session variables or configuration settings, it pins that session to the DB connection. That way, the session state remains in effect for all later transactions in the same session.

This rule doesn't apply to all parameters you can set. RDS Proxy tracks changes to the character set, collation, time zone, autocommit, current database, SQL mode, and `session_track_schema` settings. Thus RDS Proxy doesn't pin the session when you modify these. In this case, RDS Proxy only reuses the connection for other sessions that have the same values for those settings.

Performance tuning for RDS Proxy involves trying to maximize transaction-level connection reuse (multiplexing) by minimizing pinning. You can do so by doing the following:

- Avoid unnecessary database requests that might cause pinning.
- Set variables and configuration settings consistently across all connections. That way, later sessions are more likely to reuse connections that have those particular settings.

However, for PostgreSQL setting a variable leads to session pinning.

- Apply a session pinning filter to the proxy. You can exempt certain kinds of operations from pinning the session if you know that doing so doesn't affect the correct operation of your application.
- See how frequently pinning occurs by monitoring the CloudWatch metric `DatabaseConnectionsCurrentlySessionPinned`. For information about this and other CloudWatch metrics, see [Monitoring RDS Proxy using Amazon CloudWatch \(p. 192\)](#).

- If you use `SET` statements to perform identical initialization for each client connection, you can do so while preserving transaction-level multiplexing. In this case, you move the statements that set up the initial session state into the initialization query used by a proxy. This property is a string containing one or more SQL statements, separated by semicolons.

For example, you can define an initialization query for a proxy that sets certain configuration parameters. Then, RDS Proxy applies those settings whenever it sets up a new connection for that proxy. You can remove the corresponding `SET` statements from your application code, so that they don't interfere with transaction-level multiplexing.

Important

For proxies associated with MySQL databases, don't set the configuration parameter `sql_auto_is_null` to `true` or a nonzero value in the initialization query. Doing so might cause incorrect application behavior.

The proxy pins the session to the current connection in the following situations where multiplexing might cause unexpected behavior:

- Any statement with a text size greater than 16 KB causes the proxy to pin the session.
- Prepared statements cause the proxy to pin the session. This rule applies whether the prepared statement uses SQL text or the binary protocol.
- Explicit MySQL statements `LOCK TABLE`, `LOCK TABLES`, or `FLUSH TABLES WITH READ LOCK` cause the proxy to pin the session.
- Setting a user variable or a system variable (with some exceptions) causes the proxy to pin the session. If this situation reduces your connection reuse too much, you can choose for `SET` operations not to cause pinning. For information about how to do so by setting the `SessionPinningFilters` property, see [Creating an RDS Proxy \(p. 178\)](#).
- Creating a temporary table causes the proxy to pin the session. That way, the contents of the temporary table are preserved throughout the session regardless of transaction boundaries.
- Calling the MySQL functions `ROW_COUNT`, `FOUND_ROWS`, and `LAST_INSERT_ID` sometimes causes pinning.

The exact circumstances where these functions cause pinning might differ between Aurora MySQL versions that are compatible with MySQL 5.6 and MySQL 5.7.

Calling MySQL stored procedures and stored functions doesn't cause pinning. RDS Proxy doesn't detect any session state changes resulting from such calls. Therefore, make sure that your application doesn't change session state inside stored routines and rely on that session state to persist across transactions. For example, if a stored procedure creates a temporary table that is intended to persist across transactions, that application currently isn't compatible with RDS Proxy.

For PostgreSQL, the following interactions cause pinning:

- Using `SET` commands
- Using the extended query protocol such as by using JDBC default settings
- Creating temporary sequences, tables, or views
- Declaring cursors
- Discarding the session state
- Listening on a notification channel
- Loading a library module such as `auto_explain`
- Manipulating sequences using functions such as `nextval` and `setval`
- Interacting with locks using functions such as `pg_advisory_lock` and `pg_try_advisory_lock`
- Using prepared statements, setting parameters, or resetting a parameter to its default

If you have expert knowledge about your application behavior, you can skip the pinning behavior for certain application statements. To do so, choose the **Session pinning filters** option when creating the proxy. Currently, you can opt out of session pinning for setting session variables and configuration settings.

For metrics about how often pinning occurs for a proxy, see [Monitoring RDS Proxy using Amazon CloudWatch \(p. 192\)](#).

Deleting an RDS Proxy

You can delete a proxy if you no longer need it. You might delete a proxy because the application that was using it is no longer relevant. Or you might delete a proxy if you take the DB instance or cluster associated with it out of service.

AWS Management Console

To delete a proxy

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. Choose the proxy to delete from the list.
4. Choose **Delete Proxy**.

AWS CLI

To delete a DB proxy, use the AWS CLI command `delete-db-proxy`. To remove related associations, also use the `deregister-db-proxy-targets` command.

```
aws rds delete-db-proxy --name proxy_name
```

```
aws rds deregister-db-proxy-targets
  --db-proxy-name proxy_name
  [--target-group-name target_group_name]
  [--target-ids comma_separated_list]      # or
  [--db-instance-identifiers instance_id]      # or
  [--db-cluster-identifiers cluster_id]
```

RDS API

To delete a DB proxy, call the Amazon RDS API function `DeleteDBProxy`. To delete related items and associations, you also call the functions `DeleteDBProxyTargetGroup` and `DeregisterDBProxyTargets`.

Monitoring RDS Proxy using Amazon CloudWatch

You can monitor RDS Proxy by using Amazon CloudWatch. CloudWatch collects and processes raw data from the proxies into readable, near-real-time metrics. To find these metrics in the CloudWatch console, choose **Metrics**, then choose **RDS**, and choose **Per-Proxy Metrics**. For more information, see [Using Amazon CloudWatch metrics](#) in the Amazon CloudWatch User Guide.

Note

RDS publishes these metrics for each underlying Amazon EC2 instance associated with a proxy. A single proxy might be served by more than one EC2 instance. Use CloudWatch statistics to aggregate the values for a proxy across all the associated instances.

Some of these metrics might not be visible until after the first successful connection by a proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name `default` for read/write requests using the default endpoint of a proxy.

All RDS Proxy metrics are in the group `proxy`.

Each proxy endpoint has its own CloudWatch metrics. You can monitor the usage of each proxy endpoint independently. For more information about proxy endpoints, see [Endpoints for Amazon RDS Proxy \(p. 197\)](#).

You can aggregate the values for each metric using one of the following dimension sets. For example, by using the `ProxyName` dimension set, you can analyze all the traffic for a particular proxy. By using the other dimension sets, you can split the metrics in different ways. You can split the metrics based on the different endpoints or target databases of each proxy, or the read/write and read-only traffic to each database.

- Dimension set 1: `ProxyName`
- Dimension set 2: `ProxyName, EndpointName`
- Dimension set 3: `ProxyName, TargetGroup, Target`
- Dimension set 4: `ProxyName, TargetGroup, TargetRole`

Metric	Description	Valid period	CloudWatch dimension set
<code>AvailabilityPercentage</code>	The percentage of time for which the target group was available in the role indicated by the dimension. This metric is reported every minute. The most useful statistic for this metric is <code>Average</code> .	1 minute	Dimension set 4 (p. 193)
<code>ClientConnections</code>	The current number of client connections. This metric is reported every minute. The most useful statistic for this metric is <code>Sum</code> .	1 minute	Dimension set 1 (p. 193), Dimension set 2 (p. 193)
<code>ClientConnectionsClosed</code>	The number of client connections closed. The most useful statistic for this metric is <code>Sum</code> .	1 minute and above	Dimension set 1 (p. 193), Dimension set 2 (p. 193)
<code>ClientConnectionsNotEncrypted</code>	The current number of client connections without Transport Layer Security (TLS). This metric is reported every minute. The most useful statistic for this metric is <code>Sum</code> .	1 minute and above	Dimension set 1 (p. 193), Dimension set 2 (p. 193)

Metric	Description	Valid period	CloudWatch dimension set
ClientConnectionsReceived	The number of client connection requests received. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 193) , Dimension set 2 (p. 193)
ClientConnectionsSetFailed	The number of client connection attempts that failed due to misconfigured authentication or TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 193) , Dimension set 2 (p. 193)
ClientConnectionsSetEstablished	The number of client connections successfully established with any authentication mechanism with or without TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 193) , Dimension set 2 (p. 193)
ClientConnectionsTLS	The current number of client connections with TLS. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 193) , Dimension set 2 (p. 193)
DatabaseConnectionRequests	The number of requests to create a database connection. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 193) , Dimension set 3 (p. 193) , Dimension set 4 (p. 193)
DatabaseConnectionRequestsTLS	The number of requests to create a database connection with TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 193) , Dimension set 3 (p. 193) , Dimension set 4 (p. 193)
DatabaseConnections	The current number of database connections. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 193) , Dimension set 3 (p. 193) , Dimension set 4 (p. 193)

Metric	Description	Valid period	CloudWatch dimension set
DatabaseConnectionsTimeToBorrow	The time in microseconds that it takes for the proxy being monitored to get a database connection. The most useful statistic for this metric is Average.	1 minute and above	Dimension set 1 (p. 193) , Dimension set 2 (p. 193)
DatabaseConnectionsCurrentBorrow	The current number of database connections in the borrow state. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 193) , Dimension set 3 (p. 193) , Dimension set 4 (p. 193)
DatabaseConnectionsCurrentInTransaction	The current number of database connections in a transaction. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 193) , Dimension set 3 (p. 193) , Dimension set 4 (p. 193)
DatabaseConnectionsCurrentPinned	The current session count of database connections currently pinned because of operations in client requests that change session state. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 193) , Dimension set 3 (p. 193) , Dimension set 4 (p. 193)
DatabaseConnectionsFailed	The number of database connection requests that failed. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 193) , Dimension set 3 (p. 193) , Dimension set 4 (p. 193)
DatabaseConnectionsSuccessful	The number of database connections successfully established with or without TLS. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 193) , Dimension set 3 (p. 193) , Dimension set 4 (p. 193)

Metric	Description	Valid period	CloudWatch dimension set
DatabaseConnectionsTLS	The current number of database connections with TLS. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 193), Dimension set 3 (p. 193), Dimension set 4 (p. 193)
MaxDatabaseConnections	The maximum number of database connections allowed. This metric is reported every minute. The most useful statistic for this metric is Sum.	1 minute	Dimension set 1 (p. 193), Dimension set 3 (p. 193), Dimension set 4 (p. 193)
QueryDatabaseResponseTime	The time in microseconds that the database took to respond to the query. The most useful statistic for this metric is Average.	1 minute and above	Dimension set 1 (p. 193), Dimension set 2 (p. 193), Dimension set 3 (p. 193), Dimension set 4 (p. 193)
QueryRequests	The number of queries received. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 193), Dimension set 2 (p. 193)
QueryRequestsNoTLS	The number of queries received from non-TLS connections. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 193), Dimension set 2 (p. 193)
QueryRequestsTLS	The number of queries received from TLS connections. A query including multiple statements is counted as one query. The most useful statistic for this metric is Sum.	1 minute and above	Dimension set 1 (p. 193), Dimension set 2 (p. 193)

Metric	Description	Valid period	CloudWatch dimension set
QueryResponseLatency	The time in microseconds between getting a query request and the proxy responding to it. The most useful statistic for this metric is Average.	1 minute and above	Dimension set 1 (p. 193) , Dimension set 2 (p. 193)

Endpoints for Amazon RDS Proxy

Following, you can learn about endpoints for RDS Proxy and how to use them. By using endpoints, you can take advantage of the following capabilities:

- You can use multiple endpoints with a proxy to monitor and troubleshoot connections from different applications independently.
- You can use reader endpoints with Aurora DB clusters to improve read scalability and high availability for your query-intensive applications.
- You can use a cross-VPC endpoint to allow access to databases in one VPC from resources such as Amazon EC2 instances in a different VPC.

Topics

Overview of proxy endpoints

Working with RDS Proxy endpoints involves the same kinds of procedures as with Aurora DB cluster and reader endpoints and RDS instance endpoints. If you aren't familiar with RDS endpoints, find more information in [Connecting to a DB instance running the MySQL database engine](#) and [Connecting to a DB instance running the PostgreSQL database engine](#).

By default, the endpoint that you connect to when you use RDS Proxy with an Aurora cluster has read/write capability. As a consequence, this endpoint sends all requests to the writer instance of the cluster, and all of those connections count against the `max_connections` value for the writer instance. If your proxy is associated with an Aurora DB cluster, you can create additional read/write or read-only endpoints for that proxy.

You can use a read-only endpoint with your proxy for read-only queries, the same way that you use the reader endpoint for an Aurora provisioned cluster. Doing so helps you to take advantage of the read scalability of an Aurora cluster with one or more reader DB instances. You can run more simultaneous queries and make more simultaneous connections by using a read-only endpoint and adding more reader DB instances to your Aurora cluster as needed.

For a proxy endpoint that you create, you can also associate the endpoint with a different virtual private cloud (VPC) than the proxy itself uses. By doing so, you can connect to the proxy from a different VPC, for example a VPC used by a different application within your organization. Both VPCs must be owned by the same AWS account.

For information about limits associated with proxy endpoints, see [Limits for proxy endpoints \(p. 203\)](#).

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name `default` for read/write requests using the default endpoint of a proxy.

Each proxy endpoint has its own set of CloudWatch metrics. You can monitor the metrics for all endpoints of a proxy. You can also monitor metrics for a specific endpoint, or for all the read/write or read-only endpoints of a proxy. For more information, see [Monitoring RDS Proxy using Amazon CloudWatch \(p. 192\)](#).

A proxy endpoint uses the same authentication mechanism as its associated proxy. RDS Proxy automatically sets up permissions and authorizations for the user-defined endpoint, consistent with the properties of the associated proxy.

Reader endpoints

With RDS Proxy, you can create and use reader endpoints. However, these endpoints only work for proxies associated with Aurora DB clusters. You might see references to reader endpoints in the AWS Management Console. If you use the RDS CLI or API, you might see the `TargetRole` attribute with a value of `READ_ONLY`. You can take advantage of these features by changing the target of a proxy from an RDS DB instance to an Aurora DB cluster. To learn about reader endpoints, see [Managing connections with Amazon RDS Proxy in the Aurora User Guide](#).

Accessing Aurora and RDS databases across VPCs

By default, the components of your RDS and Aurora technology stack are all in the same Amazon VPC. For example, suppose that an application running on an Amazon EC2 instance connects to an Amazon RDS DB instance or an Aurora DB cluster. In this case, the application server and database must both be within the same VPC.

With RDS Proxy, you can set up access to an Aurora cluster or RDS instance in one VPC from resources such as EC2 instances in another VPC. For example, your organization might have multiple applications that access the same database resources. Each application might be in its own VPC. To use cross-VPC capability with RDS Proxy, all the VPCs must be owned by the same AWS account.

To enable cross-VPC access, you create a new endpoint for the proxy. If you aren't familiar with creating proxy endpoints, see [Endpoints for Amazon RDS Proxy \(p. 197\)](#) for details. The proxy itself resides in the same VPC as the Aurora DB cluster or RDS instance. However, the cross-VPC endpoint resides in the other VPC, along with the other resources such as the EC2 instances. The cross-VPC endpoint is associated with subnets and security groups from the same VPC as the EC2 and other resources. These associations let you connect to the endpoint from the applications that otherwise can't access the database due to the VPC restrictions.

The following steps explain how to create and access a cross-VPC endpoint through RDS Proxy:

1. Create two VPCs, or choose two VPCs that you already use for Aurora and RDS work. Each VPC should have its own associated network resources such as an Internet gateway, route tables, subnets, and security groups. If you only have one VPC, you can consult [Getting started with Amazon RDS \(p. 197\)](#) for the steps to set up another VPC to use RDS successfully. You can also examine your existing VPC in the Amazon EC2 console to see what kinds of resources to connect together.
2. Create a DB proxy associated with the Aurora DB cluster or RDS instance that you want to connect to. Follow the procedure in [Creating an RDS Proxy \(p. 178\)](#).

3. On the **Details** page for your proxy in the RDS console, under the **Proxy endpoints** section, choose **Create endpoint**. Follow the procedure in [Creating a proxy endpoint \(p. 199\)](#).
 4. Choose whether to make the cross-VPC endpoint read/write or read-only.
 5. Instead of accepting the default of the same VPC as the Aurora DB cluster or RDS instance, choose a different VPC. This VPC must be in the same AWS Region as the VPC where the proxy resides.
 6. Now instead of accepting the defaults for subnets and security groups from the same VPC as the Aurora DB cluster or RDS instance, make new selections. Make these based on the subnets and security groups from the VPC that you chose.
 7. You don't need to change any of the settings for the Secrets Manager secrets. The same credentials work for all endpoints for your proxy, regardless of which VPC each endpoint is in.
 8. Wait for the new endpoint to reach the **Available** state.
 9. Make a note of the full endpoint name. This is the value ending in **Region_name.rds.amazonaws.com** that you supply as part of the connection string for your database application.
- 10 Access the new endpoint from a resource in the same VPC as the endpoint. A simple way to test this process is to create a new EC2 instance in this VPC. Then you can log into the EC2 instance and run the `mysql` or `psql` commands to connect by using the endpoint value in your connection string.

Creating a proxy endpoint

Console

To create a proxy endpoint

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. Click the name of the proxy that you want to create a new endpoint for.

The details page for that proxy appears.

4. In the **Proxy endpoints** section, choose **Create proxy endpoint**.

The **Create proxy endpoint** window appears.

5. For **Proxy endpoint name**, enter a descriptive name of your choice.
6. For **Target role**, choose whether to make the endpoint read/write or read-only.

Connections that use a read/write endpoint can perform any kind of operation: data definition language (DDL) statements, data manipulation language (DML) statements, and queries. These endpoints always connect to the primary instance of the Aurora cluster. You can use read/write endpoints for general database operations when you only use a single endpoint in your application. You can also use read/write endpoints for administrative operations, online transaction processing (OLTP) applications, and extract-transform-load (ETL) jobs.

Connections that use a read-only endpoint can only perform queries. When there are multiple reader instances in the Aurora cluster, RDS Proxy can use a different reader instance for each connection to the endpoint. That way, a query-intensive application can take advantage of Aurora's clustering capability. You can add more query capacity to the cluster by adding more reader DB instances. These read-only connections don't impose any overhead on the primary instance of the cluster. That way, your reporting and analysis queries don't slow down the write operations of your OLTP applications.

7. For **Virtual Private Cloud (VPC)**, choose the default if you plan to access the endpoint from the same EC2 instances or other resources where you normally access the proxy or its associated database. If you want to set up cross-VPC access for this proxy, choose a VPC other than the default.

For more information about cross-VPC access, see [Accessing Aurora and RDS databases across VPCs \(p. 198\)](#).

8. For **Subnets**, RDS Proxy fills in the same subnets as the associated proxy by default. If you want to restrict access to the endpoint so that only a portion of the address range of the VPC can connect to it, remove one or more subnets from the set of choices.
9. For **VPC security group**, you can choose an existing security group or create a new one. RDS Proxy fills in the same security group or groups as the associated proxy by default. If the inbound and outbound rules for the proxy are appropriate for this endpoint, you can leave the default choice.

If you choose to create a new security group, specify a name for the security group on this page. Then edit the security group settings from the EC2 console afterward.

10. Choose **Create proxy endpoint**.

AWS CLI

To create a proxy endpoint, use the AWS CLI `create-db-proxy-endpoint` command.

Include the following required parameters:

- `--db-proxy-name value`
- `--db-proxy-endpoint-name value`
- `--vpc-subnet-ids list_of_ids`. Separate the subnet IDs with spaces. You don't specify the ID of the VPC itself.

You can also include the following optional parameters:

- `--target-role { READ_WRITE | READ_ONLY }`. This parameter defaults to `READ_WRITE`. The `READ_ONLY` value only has an effect on Aurora provisioned clusters that contain one or more reader DB instances. When the proxy is associated with an RDS instance or with an Aurora cluster that only contains a writer DB instance, you can't specify `READ_ONLY`.
- `--vpc-security-group-ids value`. Separate the security group IDs with spaces. If you omit this parameter, RDS Proxy uses the default security group for the VPC. RDS Proxy determines the VPC based on the subnet IDs that you specify for the `--vpc-subnet-ids` parameter.

Example

The following example creates a proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```
aws rds create-db-proxy-endpoint \
--db-proxy-name my-proxy \
--db-proxy-endpoint-name my-endpoint \
--vpc-subnet-ids subnet_id subnet_id subnet_id ... \
--target-role READ_ONLY \
--vpc-security-group-ids security_group_id ]
```

For Windows:

```
aws rds create-db-proxy-endpoint ^
--db-proxy-name my-proxy ^
--db-proxy-endpoint-name my-endpoint ^
--vpc-subnet-ids subnet_id_1 subnet_id_2 subnet_id_3 ... ^
--target-role READ_ONLY ^
--vpc-security-group-ids security_group_id
```

RDS API

To create a proxy endpoint, use the RDS API [CreateProxyEndpoint](#) action.

Viewing proxy endpoints

Console

To view the details for a proxy endpoint

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to view. Click the proxy name to view its details page.
4. In the **Proxy endpoints** section, choose the endpoint that you want to view. Click its name to view the details page.
5. Examine the parameters whose values you're interested in. You can check properties such as the following:
 - Whether the endpoint is read/write or read-only.
 - The endpoint address that you use in a database connection string.
 - The VPC, subnets, and security groups associated with the endpoint.

AWS CLI

To view one or more DB proxy endpoints, use the AWS CLI [describe-db-proxy-endpoints](#) command.

You can include the following optional parameters:

- `--db-proxy-endpoint-name`
- `--db-proxy-name`

The following example describes the `my-endpoint` proxy endpoint.

Example

For Linux, macOS, or Unix:

```
aws rds describe-db-proxy-endpoints \
--db-proxy-endpoint-name my-endpoint
```

For Windows:

```
aws rds describe-db-proxy-endpoints ^
--db-proxy-endpoint-name my-endpoint
```

RDS API

To describe one or more proxy endpoints, use the RDS API [DescribeDBProxyEndpoints](#) operation.

Modifying a proxy endpoint

Console

To modify one or more proxy endpoints

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Proxies**.
3. In the list, choose the proxy whose endpoint you want to modify. Click the proxy name to view its details page.
4. In the **Proxy endpoints** section, choose the endpoint that you want to modify. You can select it in the list, or click its name to view the details page.
5. On the proxy details page, under the **Proxy endpoints** section, choose **Edit**. Or on the proxy endpoint details page, for **Actions**, choose **Edit**.
6. Change the values of the parameters that you want to modify.
7. Choose **Save changes**.

AWS CLI

To modify a DB proxy endpoint, use the AWS CLI `modify-db-proxy-endpoint` command with the following required parameters:

- `--db-proxy-endpoint-name`

Specify changes to the endpoint properties by using one or more of the following parameters:

- `--new-db-proxy-endpoint-name`
- `--vpc-security-group-ids`. Separate the security group IDs with spaces.

The following example renames the `my-endpoint` proxy endpoint to `new-endpoint-name`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-proxy-endpoint \
--db-proxy-endpoint-name my-endpoint \
--new-db-proxy-endpoint-name new-endpoint-name
```

For Windows:

```
aws rds modify-db-proxy-endpoint ^
--db-proxy-endpoint-name my-endpoint ^
--new-db-proxy-endpoint-name new-endpoint-name
```

RDS API

To modify a proxy endpoint, use the RDS API [ModifyDBProxyEndpoint](#) operation.

Deleting a proxy endpoint

You can delete an endpoint for your proxy using the console as described following.

Note

You can't delete the default endpoint that RDS Proxy automatically creates for each proxy. When you delete a proxy, RDS Proxy automatically deletes all the associated endpoints.

Console

To delete a proxy endpoint using the AWS Management Console

1. In the navigation pane, choose **Proxies**.
2. In the list, choose the proxy whose endpoint you want to endpoint. Click the proxy name to view its details page.
3. In the **Proxy endpoints** section, choose the endpoint that you want to delete. You can select one or more endpoints in the list, or click the name of a single endpoint to view the details page.
4. On the proxy details page, under the **Proxy endpoints** section, choose **Delete**. Or on the proxy endpoint details page, for **Actions**, choose **Delete**.

AWS CLI

To delete a proxy endpoint, run the `delete-db-proxy-endpoint` command with the following required parameters:

- `--db-proxy-endpoint-name`

The following command deletes the proxy endpoint named `my-endpoint`.

For Linux, macOS, or Unix:

```
aws rds delete-db-proxy-endpoint \
--db-proxy-endpoint-name my-endpoint
```

For Windows:

```
aws rds delete-db-proxy-endpoint ^
--db-proxy-endpoint-name my-endpoint
```

RDS API

To delete a proxy endpoint with the RDS API, run the `DeleteDBProxyEndpoint` operation. Specify the name of the proxy endpoint for the `DBProxyEndpointName` parameter.

Limits for proxy endpoints

Each proxy has a default endpoint that you can modify but not create or delete.

The maximum number of user-defined endpoints for a proxy is 20. Thus, a proxy can have up to 21 endpoints: the default endpoint, plus 20 that you create.

When you associate additional endpoints with a proxy, RDS Proxy automatically determines which DB instances in your cluster to use for each endpoint. You can't choose specific instances the way that you can with Aurora custom endpoints.

To use cross-VPC capability with RDS Proxy, all the VPCs must be owned by the same AWS account.

Reader endpoints aren't available for Aurora multi-writer clusters.

You can connect to proxy endpoints that you create using the SSL modes `REQUIRED` and `VERIFY_CA`. You can't connect to an endpoint that you create using the SSL mode `VERIFY_IDENTITY`.

Command-line examples for RDS Proxy

To see how combinations of connection commands and SQL statements interact with RDS Proxy, look at the following examples.

Examples

- [Preserving Connections to a MySQL Database Across a Failover](#)
- [Adjusting the max_connections Setting for an Aurora DB Cluster](#)

Example Preserving connections to a MySQL database across a failover

This MySQL example demonstrates how open connections continue working during a failover, for example when you reboot a database or it becomes unavailable due to a problem. This example uses a proxy named `the-proxy` and an Aurora DB cluster with DB instances `instance-8898` and `instance-9814`. When you run the `failover-db-cluster` command from the Linux command line, the writer instance that the proxy is connected to changes to a different DB instance. You can see that the DB instance associated with the proxy changes while the connection remains open.

```
$ mysql -h the-proxy.proxy-demo.us-east-1.rds.amazonaws.com -u admin_user -p
Enter password:
...
mysql> select @@aurora_server_id;
+-----+
| @@aurora_server_id |
+-----+
| instance-9814      |
+-----+
1 row in set (0.01 sec)

mysql>

Example Adjusting the max_connections setting for an Aurora DB cluster

This example demonstrates how you can adjust the max_connections setting for an Aurora MySQL DB cluster. To do so, you create your own DB cluster parameter group based on the default parameter settings for clusters that are compatible with MySQL 5.6 or 5.7. You specify a value for the max_connections setting, overriding the formula that sets the default value. You associate the DB cluster parameter group with your DB cluster.

```
export REGION=us-east-1
export CLUSTER_PARAM_GROUP=rds-proxy-mysql-56-max-connections-demo
export CLUSTER_NAME=rds-proxy-mysql-56

aws rds create-db-parameter-group --region $REGION \
--db-parameter-group-family aurora5.6 \
--db-parameter-group-name $CLUSTER_PARAM_GROUP \
--description "Aurora MySQL 5.6 cluster parameter group for RDS Proxy demo."

aws rds modify-db-cluster --region $REGION \
--db-cluster-identifier $CLUSTER_NAME \
--db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP

echo "New cluster param group is assigned to cluster:"
aws rds describe-db-clusters --region $REGION \
--db-cluster-identifier $CLUSTER_NAME \
--query '*[*].{DBClusterParameterGroup:DBClusterParameterGroup}'

echo "Current value for max_connections:"
aws rds describe-db-cluster-parameters --region $REGION \
--db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP \
--query '*[*].{ParameterName:ParameterName,ParameterValue:ParameterValue}' \
--output text | grep "max_connections"

echo -n "Enter number for max_connections setting: "
read answer

aws rds modify-db-cluster-parameter-group --region $REGION --db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP \
--parameters "ParameterName=max_connections,ParameterValue=$answer,ApplyMethod=immediate"

echo "Updated value for max_connections:"
aws rds describe-db-cluster-parameters --region $REGION \
--db-cluster-parameter-group-name $CLUSTER_PARAM_GROUP \
--query '*[*].{ParameterName:ParameterName,ParameterValue:ParameterValue}' \
--output text | grep "max_connections"
```

Troubleshooting for RDS Proxy

Following, you can find troubleshooting ideas for some common RDS Proxy issues and information on CloudWatch logs for RDS Proxy.

In the RDS Proxy logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name you specified for a user-defined endpoint, or the special name default for read/write requests using the default endpoint of a proxy. For more information about proxy endpoints, see [Endpoints for Amazon RDS Proxy \(p. 197\)](#).

Topics

- [Common issues and solutions \(p. 206\)](#)
- [Working with CloudWatch logs for RDS Proxy \(p. 210\)](#)
- [Verifying connectivity for a proxy \(p. 210\)](#)

Common issues and solutions

For possible causes and solutions to some common problems that you might encounter using RDS Proxy, see the following.

You might encounter the following issues while creating a new proxy or connecting to a proxy.

Error	Causes or workarounds
403: The security token included in the request is invalid	Select an existing IAM role instead of choosing to create a new one.

You might encounter the following issues while connecting to a MySQL proxy.

Error	Causes or workarounds
ERROR 1040 (HY000): Connections rate limit exceeded (<i>limit_value</i>)	The rate of connection requests from the client to the proxy has exceeded the limit.
ERROR 1040 (HY000): IAM authentication rate limit exceeded	The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.
ERROR 1040 (HY000): Number simultaneous connections exceeded (<i>limit_value</i>)	The number of simultaneous connection requests from the client to the proxy exceeded the limit.
ERROR 1045 (28000): Access denied for user ' <i>DB_USER</i> '@'%' (using password: YES)	Some possible reasons include the following: <ul style="list-style-type: none">• The Secrets Manager secret used by the proxy doesn't match the user name and password of an existing database user. Either update the credentials in the Secrets Manager secret, or make sure the database user exists and has the same password as in the secret.
ERROR 1105 (HY000): Unknown error	An unknown error occurred.
ERROR 1231 (42000): Variable	The value set for the character_set_client parameter is not valid. For example, the value ucs2 is not valid because it can crash the MySQL server.

Error	Causes or workarounds
'character_set_client' can't be set to the value of <code>value</code>	
ERROR 3159 (HY000): This RDS Proxy requires TLS connections.	You enabled the setting Require Transport Layer Security in the proxy but your connection included the parameter <code>ssl-mode=DISABLED</code> in the MySQL client. Do either of the following: <ul style="list-style-type: none"> Disable the setting Require Transport Layer Security for the proxy. Connect to the database using the minimum setting of <code>ssl-mode=REQUIRED</code> in the MySQL client.
ERROR 2026 (HY000): SSL connection error: Internal Server <code>Error</code>	The TLS handshake to the proxy failed. Some possible reasons include the following: <ul style="list-style-type: none"> SSL is required but the server doesn't support it. An internal server error occurred. A bad handshake occurred.
ERROR 9501 (HY000): Timed- out waiting to acquire database connection	The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following: <ul style="list-style-type: none"> The proxy is unable to establish a database connection because the maximum connections have been reached The proxy is unable to establish a database connection because the database is unavailable.

You might encounter the following issues while connecting to a PostgreSQL proxy.

Error	Cause	Solution
IAM authentication is allowed only with SSL connections.	The user tried to connect to the database using IAM authentication with the setting <code>sslmode=disable</code> in the PostgreSQL client.	The user needs to connect to the database using the minimum setting of <code>sslmode=require</code> in the PostgreSQL client. For more information, see the PostgreSQL SSL support documentation.
This RDS Proxy requires TLS connections.	The user enabled the option Require Transport Layer Security but tried to connect with <code>sslmode=disable</code> in the PostgreSQL client.	To fix this error, do one of the following: <ul style="list-style-type: none"> Disable the proxy's Require Transport Layer Security option. Connect to the database using the minimum setting of <code>sslmode=allow</code> in the PostgreSQL client.
IAM authentication failed for user <code>user_name</code> . Check the IAM token for this user and try again.	This error might be due to the following reasons: <ul style="list-style-type: none"> The client supplied the incorrect IAM user name. 	To fix this error, do the following: <ol style="list-style-type: none"> Confirm that the provided IAM user exists.

Error	Cause	Solution
	<ul style="list-style-type: none"> The client supplied an incorrect IAM authorization token for the user. The client is using an IAM policy that does not have the necessary permissions. The client supplied an expired IAM authorization token for the user. 	2. Confirm that the IAM authorization token belongs to the provided IAM user. 3. Confirm that the IAM policy has adequate permissions for RDS. 4. Check the validity of the IAM authorization token used.
This RDS proxy has no credentials for the role <i>role_name</i> . Check the credentials for this role and try again.	There is no Secrets Manager secret for this role.	Add a Secrets Manager secret for this role.
RDS supports only IAM or MD5 authentication.	The database client being used to connect to the proxy is using an authentication mechanism not currently supported by the proxy, such as SCRAM-SHA-256.	If you're not using IAM authentication, use the MD5 password authentication only.
A user name is missing from the connection startup packet. Provide a user name for this connection.	The database client being used to connect to the proxy isn't sending a user name when trying to establish a connection.	Make sure to define a user name when setting up a connection to the proxy using the PostgreSQL client of your choice.
Feature not supported: RDS Proxy supports only version 3.0 of the PostgreSQL messaging protocol.	The PostgreSQL client used to connect to the proxy uses a protocol older than 3.0.	Use a newer PostgreSQL client that supports the 3.0 messaging protocol. If you're using the PostgreSQL <code>psql</code> CLI, use a version greater than or equal to 7.4.
Feature not supported: RDS Proxy currently doesn't support streaming replication mode.	The PostgreSQL client used to connect to the proxy is trying to use the streaming replication mode, which isn't currently supported by RDS Proxy.	Turn off the streaming replication mode in the PostgreSQL client being used to connect.
Feature not supported: RDS Proxy currently doesn't support the option <i>option_name</i> .	Through the startup message, the PostgreSQL client used to connect to the proxy is requesting an option that isn't currently supported by RDS Proxy.	Turn off the option being shown as not supported from the message above in the PostgreSQL client being used to connect.
The IAM authentication failed because of too many competing requests.	The number of simultaneous requests with IAM authentication from the client to the proxy has exceeded the limit.	Reduce the rate in which connections using IAM authentication from a PostgreSQL client are established.

Error	Cause	Solution
The maximum number of client connections to the proxy exceeded <code>number_value</code> .	The number of simultaneous connection requests from the client to the proxy exceeded the limit.	Reduce the number of active connections from PostgreSQL clients to this RDS proxy.
Rate of connection to proxy exceeded <code>number_value</code> .	The rate of connection requests from the client to the proxy has exceeded the limit.	Reduce the rate at which connections from a PostgreSQL client are established.
The password that was provided for the role <code>role_name</code> is wrong.	The password for this role doesn't match the Secrets Manager secret.	Check the secret for this role in Secrets Manager to see if the password is the same as what's being used in your PostgreSQL client.
The IAM authentication failed for the role <code>role_name</code> . Check the IAM token for this role and try again.	There is a problem with the IAM token used for IAM authentication.	Generate a new authentication token and use it in a new connection.
IAM is allowed only with SSL connections.	A client tried to connect using IAM authentication, but SSL wasn't enabled.	Enable SSL in the PostgreSQL client.
Unknown error.	An unknown error occurred.	Reach out to AWS Support for us to investigate the issue.
Timed-out waiting to acquire database connection.	<p>The proxy timed-out waiting to acquire a database connection. Some possible reasons include the following:</p> <ul style="list-style-type: none"> The proxy can't establish a database connection because the maximum connections have been reached. The proxy can't establish a database connection because the database is unavailable. 	<p>Possible solutions are:</p> <ul style="list-style-type: none"> Check the target of the RDS DB instance or Aurora DB cluster status to see if it's unavailable. Check if there are long-running transactions and/or queries being executed. They can use database connections from the connection pool for a long time.
Request returned an error: <code>database_error</code> .	The database connection established from the proxy returned an error.	The solution depends on the specific database error. One example is: Request returned an error: database "your-database-name" does not exist. This means the specified database name, or the user name used as a database name (in case a database name hasn't been specified), doesn't exist in the database server.

Working with CloudWatch logs for RDS Proxy

You can find logs of RDS Proxy activity under CloudWatch in the AWS Management Console. Each proxy has an entry in the **Log groups** page.

Important

These logs are intended for human consumption for troubleshooting purposes and not for programmatic access. The format and content of the logs is subject to change.

In particular, older logs don't contain any prefixes indicating the endpoint for each request. In newer logs, each entry is prefixed with the name of the associated proxy endpoint. This name can be the name that you specified for a user-defined endpoint, or the special name `default` for requests using the default endpoint of a proxy.

Verifying connectivity for a proxy

You can use the following commands to verify that all components of the connection mechanism can communicate with the other components.

Examine the proxy itself using the [describe-db-proxies](#) command. Also examine the associated target group using the [describe-db-proxy-target-groups](#). Check that the details of the targets match the RDS DB instance or Aurora DB cluster that you intend to associate with the proxy. Use commands such as the following.

```
aws rds describe-db-proxies --db-proxy-name $DB_PROXY_NAME
aws rds describe-db-proxy-target-groups --db-proxy-name $DB_PROXY_NAME
```

To confirm that the proxy can connect to the underlying database, examine the targets specified in the target groups using the [describe-db-proxy-targets](#) command. Use a command such as the following.

```
aws rds describe-db-proxy-targets --db-proxy-name $DB_PROXY_NAME
```

The output of the [describe-db-proxy-targets](#) command includes a `TargetHealth` field. You can examine the fields `State`, `Reason`, and `Description` inside `TargetHealth` to check if the proxy can communicate with the underlying DB instance.

- A `State` value of `AVAILABLE` indicates that the proxy can connect to the DB instance.
- A `State` value of `UNAVAILABLE` indicates a temporary or permanent connection problem. In this case, examine the `Reason` and `Description` fields. For example, if `Reason` has a value of `PENDING_PROXY_CAPACITY`, try connecting again after the proxy finishes its scaling operation. If `Reason` has a value of `UNREACHABLE`, `CONNECTION_FAILED`, or `AUTH_FAILURE`, use the explanation from the `Description` field to help you diagnose the issue.
- The `State` field might have a value of `REGISTERING` for a brief time before changing to `AVAILABLE` or `UNAVAILABLE`.

If the following Netcat command (`nc`) is successful, you can access the proxy endpoint from the EC2 instance or other system where you're logged in. This command reports failure if you're not in the same VPC as the proxy and the associated database. You might be able to log directly in to the database without being in the same VPC. However, you can't log into the proxy unless you're in the same VPC.

```
nc -zx MySQL_proxy_endpoint 3306
nc -zx PostgreSQL_proxy_endpoint 5432
```

You can use the following commands to make sure that your EC2 instance has the required properties. In particular, the VPC for the EC2 instance must be the same as the VPC for the RDS DB instance or Aurora DB cluster that the proxy connects to.

```
aws ec2 describe-instances --instance-ids your_ec2_instance_id
```

Examine the Secrets Manager secrets used for the proxy.

```
aws secretsmanager list-secrets
aws secretsmanager get-secret-value --secret-id your_secret_id
```

Make sure that the `SecretString` field displayed by `get-secret-value` is encoded as a JSON string that includes `username` and `password` fields. The following example shows the format of the `SecretString` field.

```
{
  "ARN": "some_arn",
  "Name": "some_name",
  "VersionId": "some_version_id",
  "SecretString": '{"username":"some_username","password":"some_password"}',
  "VersionStages": [ "some_stage" ],
  "CreatedDate": some_timestamp
}
```

Using RDS Proxy with AWS CloudFormation

You can use RDS Proxy with AWS CloudFormation. Doing so helps you to create groups of related resources, including a proxy that can connect to a newly created Amazon RDS DB instance or Aurora DB cluster. RDS Proxy support in AWS CloudFormation involves two new registry types: `DBProxy` and `DBProxyTargetGroup`.

The following listing shows a sample AWS CloudFormation template for RDS Proxy.

```
Resources:
  DBProxy:
    Type: AWS::RDS::DBProxy
    Properties:
      DBProxyName: CanaryProxy
      EngineFamily: MYSQL
      RoleArn:
        Fn::ImportValue: SecretReaderRoleArn
      Auth:
        - {AuthScheme: SECRETS, SecretArn: !ImportValue ProxySecret, IAMAuth: DISABLED}
      VpcSubnetIds:
        Fn::Split: [",", "Fn::ImportValue": SubnetIds]

  ProxyTargetGroup:
    Type: AWS::RDS::DBProxyTargetGroup
    Properties:
      DBProxyName: CanaryProxy
      TargetGroupName: default
      DBInstanceIdentifiers:
        - Fn::ImportValue: DBInstanceName
      DependsOn: DBProxy
```

For more information about the Amazon RDS and Aurora resources that you can create using AWS CloudFormation, see [RDS resource type reference](#).

Working with option groups

Some DB engines offer additional features that make it easier to manage data and databases, and to provide additional security for your database. Amazon RDS uses option groups to enable and configure these features. An *option group* can specify features, called options, that are available for a particular Amazon RDS DB instance. Options can have settings that specify how the option works. When you associate a DB instance with an option group, the specified options and option settings are enabled for that DB instance.

Amazon RDS supports options for the following database engines:

Database engine	Relevant documentation
MariaDB	Options for MariaDB database engine (p. 616)
Microsoft SQL Server	Options for the Microsoft SQL Server database engine (p. 749)
MySQL	Options for MySQL DB instances (p. 925)
Oracle	Adding options to Oracle DB instances (p. 1126)
PostgreSQL	PostgreSQL does not use options and option groups. PostgreSQL uses extensions and modules to provide additional features. For more information, see PostgreSQL extensions supported on Amazon RDS (p. 1482) .

Option groups overview

Amazon RDS provides an empty default option group for each new DB instance. You cannot modify this default option group, but any new option group that you create derives its settings from the default option group. To apply an option to a DB instance, you must do the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add one or more options to the option group.
3. Associate the option group with the DB instance.

To associate an option group with a DB instance, modify the DB instance. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

Both DB instances and DB snapshots can be associated with an option group. In some cases, you might restore from a DB snapshot or perform a point-in-time restore for a DB instance. In these cases, the option group associated with the DB snapshot or DB instance is, by default, associated with the restored DB instance. You can associate a different option group with a restored DB instance. However, the new option group must contain any persistent or permanent options that were included in the original option group. Persistent and permanent options are described following.

Options require additional memory to run on a DB instance. Thus, you might need to launch a larger instance to use them, depending on your current use of your DB instance. For example, Oracle Enterprise Manager Database Control uses about 300 MB of RAM. If you enable this option for a small DB instance, you might encounter performance problems or out-of-memory errors.

Persistent and permanent options

Two types of options, persistent and permanent, require special consideration when you add them to an option group.

Persistent options can't be removed from an option group while DB instances are associated with the option group. An example of a persistent option is the TDE option for Microsoft SQL Server transparent data encryption (TDE). You must disassociate all DB instances from the option group before a persistent option can be removed from the option group. In some cases, you might restore or perform a point-in-time restore from a DB snapshot. In these cases, if the option group associated with that DB snapshot contains a persistent option, you can only associate the restored DB instance with that option group.

Permanent options, such as the TDE option for Oracle Advanced Security TDE, can never be removed from an option group. You can change the option group of a DB instance that is using the permanent option. However, the option group associated with the DB instance must include the same permanent option. In some cases, you might restore or perform a point-in-time restore from a DB snapshot. In these cases, if the option group associated with that DB snapshot contains a permanent option, you can only associate the restored DB instance with an option group with that permanent option.

For Oracle DB instances, you can copy shared DB snapshots that have the options `Timezone` or `OLS` (or both). To do so, specify a target option group that includes these options when you copy the DB snapshot. The OLS option is permanent and persistent only for Oracle DB instances running Oracle version 12.2 or higher. For more information about these options, see [Oracle time zone \(p. 1201\)](#) and [Oracle Label Security \(p. 1167\)](#).

VPC and platform considerations

When an option group is assigned to a DB instance, it is linked to the platform that the DB instance is on. That platform can either be a VPC supported by the Amazon VPC service, or EC2-Classic (non-VPC) supported by the Amazon EC2 service. For details on these two platforms, see [Amazon EC2 and Amazon Virtual Private Cloud](#).

If a DB instance is in a VPC, the option group associated with the instance is linked to that VPC. This means that you can't use the option group assigned to a DB instance if you try to restore the instance to a different VPC or a different platform. If you restore a DB instance to a different VPC or a different platform, you can do one of the following:

- Assign the default option group to the DB instance.
- Assign an option group that is linked to that VPC or platform.
- Create a new option group and assign it to the DB instance.

With persistent or permanent options, such as Oracle TDE, you must create a new option group that includes the persistent or permanent option when restoring a DB instance into a different VPC.

Option settings control the behavior of an option. For example, the Oracle Advanced Security option `NATIVE_NETWORK_ENCRYPTION` has a setting that you can use to specify the encryption algorithm for network traffic to and from the DB instance. Some options settings are optimized for use with Amazon RDS and cannot be changed.

Mutually exclusive options

Some options are mutually exclusive. You can use one or the other, but not both at the same time. The following options are mutually exclusive:

- [Oracle Enterprise Manager Database Express \(p. 1150\)](#) and [Oracle Management Agent for Enterprise Manager Cloud Control \(p. 1154\)](#).
- [Oracle native network encryption \(p. 1176\)](#) and [Oracle Secure Sockets Layer \(p. 1182\)](#).

Creating an option group

You can create a new option group that derives its settings from the default option group, and then add one or more options to the new option group. Alternatively, if you already have an existing option group, you can copy that option group with all of its options to a new option group. For more information, see [Copying an option group \(p. 215\)](#).

After you create a new option group, it has no options. To learn how to add options to the option group, see [Adding an option to an option group \(p. 216\)](#). After you have added the options you want, you can then associate the option group with a DB instance so that the options become available on the DB instance. For information about associating an option group with a DB instance, see the documentation for your specific engine listed at [Working with option groups \(p. 212\)](#).

Console

One way of creating an option group is by using the AWS Management Console.

To create a new option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** window, do the following:
 - a. For **Name**, type a name for the option group that is unique within your AWS account. The name can contain only letters, digits, and hyphens.
 - b. For **Description**, type a brief description of the option group. The description is used for display purposes.
 - c. For **Engine**, choose the DB engine that you want.
 - d. For **Major engine version**, choose the major version of the DB engine that you want.
5. To continue, choose **Create**. To cancel the operation instead, choose **Cancel**.

AWS CLI

To create an option group, use the AWS CLI `create-option-group` command with the following required parameters.

- `--option-group-name`
- `--engine-name`
- `--major-engine-version`
- `--option-group-description`

Example

The following example creates an option group named `testoptiongroup`, which is associated with the Oracle Enterprise Edition DB engine. The description is enclosed in quotation marks.

For Linux, macOS, or Unix:

```
aws rds create-option-group \
```

```
--option-group-name testoptiongroup \
--engine-name oracle-ee \
--major-engine-version 12.1 \
--option-group-description "Test option group"
```

For Windows:

```
aws rds create-option-group ^
--option-group-name testoptiongroup ^
--engine-name oracle-ee ^
--major-engine-version 12.1 ^
--option-group-description "Test option group"
```

RDS API

To create an option group, call the Amazon RDS API [CreateOptionGroup](#) operation. Include the following parameters:

- `OptionGroupName`
- `EngineName`
- `MajorEngineVersion`
- `OptionGroupDescription`

Copying an option group

You can use the AWS CLI or the Amazon RDS API copy an option group. Copying an option group is convenient when you have an existing option group and you want to include most of its custom parameters and values in a new option group. You can also make a copy of an option group that you use in production and then modify the copy to test other option settings.

Note

Currently, you can't copy an option group to a different AWS Region.

AWS CLI

To copy an option group, use the AWS CLI [copy-option-group](#) command. Include the following required options:

- `--source-option-group-identifier`
- `--target-option-group-identifier`
- `--target-option-group-description`

Example

The following example creates an option group named `new-option-group`, which is a local copy of the option group `my-option-group`.

For Linux, macOS, or Unix:

```
aws rds copy-option-group \
--source-option-group-identifier my-option-group \
```

```
--target-option-group-identifier new-option-group \
--target-option-group-description "My new option group"
```

For Windows:

```
aws rds copy-option-group ^
--source-option-group-identifier my-option-group ^
--target-option-group-identifier new-option-group ^
--target-option-group-description "My new option group"
```

RDS API

To copy an option group, call the Amazon RDS API [CopyOptionGroup](#) operation. Include the following required parameters.

- `SourceOptionGroupIdentifier`
- `TargetOptionGroupIdentifier`
- `TargetOptionGroupDescription`

Adding an option to an option group

You can add an option to an existing option group. After you have added the options you want, you can then associate the option group with a DB instance so that the options become available on the DB instance. For information about associating an option group with a DB instance, see the documentation for your specific DB engine listed at [Working with option groups \(p. 212\)](#).

Option group changes must be applied immediately in two cases:

- When you add an option that adds or updates a port value, such as the `OEM` option.
- When you add or remove an option group with an option that includes a port value.

In these cases, choose the **Apply Immediately** option in the console. Or you can include the `--apply-immediately` option when using the AWS CLI or set the `ApplyImmediately` parameter to `true` when using the Amazon RDS API. Options that don't include port values can be applied immediately, or can be applied during the next maintenance window for the DB instance.

Note

If you specify a security group as a value for an option in an option group, you manage the security group by modifying the option group. You can't change or remove this security group by modifying a DB instance. Also, the security group doesn't appear in the DB instance details in the AWS Management Console or in the output for the AWS CLI command `describe-db-instances`.

Console

You can use the AWS Management Console to add an option to an option group.

To add an option to an option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you want to modify, and then choose **Add option**.

Option groups (9)		
<input type="text"/> Filter subnet groups		
	Name	Description
<input type="checkbox"/>	carpcmysql	carpcmysql
<input checked="" type="checkbox"/>	carpcoracle	carpcoracle
<input type="checkbox"/>	default:mysql-5-5	Default option group for mysql 5.5
<input type="checkbox"/>	default:mysql-5-6	Default option group for mysql 5.6
<input type="checkbox"/>	default:mysql-5-7	Default option group for mysql 5.7

4. In the **Add option** window, do the following:

- a. Choose the option that you want to add. You might need to provide additional values, depending on the option that you select. For example, when you choose the **OEM** option, you must also type a port value and specify a security group.
- b. To enable the option on all associated DB instances as soon as you add it, for **Apply Immediately**, choose **Yes**. If you choose **No** (the default), the option is enabled for each associated DB instance during its next maintenance window.

Add Option

Option details

Option group name
carpcoracle

Option
Name of Option you want to add to this group

Port
The port number, if applicable, to use when connecting to the Option

Security Groups
A list of VPC or DB Security Groups for which this Option is enabled

default

Apply Immediately [info](#)
 Yes
 No

- When the settings are as you want them, choose **Add option**.

AWS CLI

To add an option to an option group, run the AWS CLI [add-option-to-option-group](#) command with the option that you want to add. To enable the new option immediately on all associated DB instances, include the `--apply-immediately` parameter. By default, the option is enabled for each associated DB instance during its next maintenance window. Include the following required parameter:

- `--option-group-name`

Example

The following example adds the Oracle Enterprise Manager Database Control (OEM) option to an option group named `testoptiongroup` and immediately enables it. Even if you use the default security group, you must specify that security group.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
```

```
--option-group-name testoptiongroup \
--options OptionName=OEM,Port=5500,DBSecurityGroupMemberships=default \
--apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
--option-group-name testoptiongroup ^
--options OptionName=OEM,Port=5500,DBSecurityGroupMemberships=default ^
--apply-immediately
```

Command output is similar to the following:

```
OPTIONGROUP  False  oracle-ee  12.1  arn:aws:rds:us-east-1:1234567890:og:testoptiongroup
Test Option Group  testoptiongroup default
OPTIONS Oracle 12c EM Express  OEM      False    False   5500
DBSECURITYGROUPEMEMBERSHIPS  default authorized
```

Example

The following example adds the Oracle OEM option to an option group. It also specifies a custom port and a pair of Amazon EC2 VPC security groups to use for that port.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
--option-group-name testoptiongroup \
--options OptionName=OEM,Port=5500,VpcSecurityGroupMemberships="sg-test1,sg-test2" \
--apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
--option-group-name testoptiongroup ^
--options OptionName=OEM,Port=5500,VpcSecurityGroupMemberships="sg-test1,sg-test2" ^
--apply-immediately
```

Command output is similar to the following:

```
OPTIONGROUP  False  oracle-ee  12.1  arn:aws:rds:us-east-1:1234567890:og:testoptiongroup
Test Option Group  testoptiongroup vpc-test
OPTIONS Oracle 12c EM Express  OEM      False    False   5500
VPCSECURITYGROUPEMEMBERSHIPS  active  sg-test1
VPCSECURITYGROUPEMEMBERSHIPS  active  sg-test2
```

Example

The following example adds the Oracle option NATIVE_NETWORK_ENCRYPTION to an option group and specifies the option settings. If no option settings are specified, default values are used.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
--option-group-name testoptiongroup \
--options '[{"OptionSettings": [{"Name": "SQLNET.ENCRYPTION_SERVER", "Value": "REQUIRED"}, {"Name": "SQLNET.ENCRYPTION_TYPES_SERVER", "Value": "AES256,AES192,DES"}]}, {"OptionName": "NATIVE_NETWORK_ENCRYPTION", "Value": "AES256,AES192,DES"}]' \
--apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
--option-group-name testoptiongroup ^
--options "OptionSettings=[{ "Name": "SQLNET.ENCRYPTION_SERVER", "Value": "REQUIRED"}, { "Name": "SQLNET.ENCRYPTION_TYPES_SERVER", "Value": "AES256\,AES192\,DES"}], "OptionName": "NATIVE_NETWORK_ENCRYPTION", ^
--apply-immediately
```

Command output is similar to the following:

```
OPTIONGROUP False oracle-ee 12.1 arn:aws:rds:us-east-1:1234567890:og:testoptiongroup
Test Option Group testoptiongroup
OPTIONS Oracle Advanced Security - Native Network Encryption      NATIVE_NETWORK_ENCRYPTION
      False False
OPTIONSETTINGS
      RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40
          STATIC STRING
      RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40      Specifies
          list of encryption algorithms in order of intended use
      True True SQLNET.ENCRYPTION_TYPES_SERVER AES256,AES192,DES
OPTIONSETTINGS ACCEPTED,REJECTED,REQUESTED,REQUIRED STATIC STRING REQUESTED
          Specifies the desired encryption behavior False True SQLNET.ENCRYPTION_SERVER
          REQUIRED
OPTIONSETTINGS SHA1,MD5 STATIC STRING SHA1,MD5 Specifies list of checksumming
          algorithms in order of intended use True True SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER
          SHA1,MD5
```

RDS API

To add an option to an option group using the Amazon RDS API, call the [ModifyOptionGroup](#) operation with the option that you want to add. To enable the new option immediately on all associated DB instances, include the `ApplyImmediately` parameter and set it to `true`. By default, the option is enabled for each associated DB instance during its next maintenance window. Include the following required parameter:

- `OptionGroupName`

Listing the options and option settings for an option group

You can list all the options and option settings for an option group.

Console

You can use the AWS Management Console to list all of the options and option settings for an option group.

To list the options and option settings for an option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the name of the option group to display its details. The options and option settings in the option group are listed.

AWS CLI

To list the options and option settings for an option group, use the AWS CLI `describe-option-groups` command. Specify the name of the option group whose options and settings you want to view. If you don't specify an option group name, all option groups are described.

Example

The following example lists the options and option settings for all option groups.

```
aws rds describe-option-groups
```

Example

The following example lists the options and option settings for an option group named `testoptiongroup`.

```
aws rds describe-option-groups --option-group-name testoptiongroup
```

RDS API

To list the options and option settings for an option group, use the Amazon RDS API `DescribeOptionGroups` operation. Specify the name of the option group whose options and settings you want to view. If you don't specify an option group name, all option groups are described.

Modifying an option setting

After you have added an option that has modifiable option settings, you can modify the settings at any time. If you change options or option settings in an option group, those changes are applied to all DB instances that are associated with that option group. For more information on what settings are available for the various options, see the documentation for your specific engine listed at [Working with option groups \(p. 212\)](#).

Option group changes must be applied immediately in two cases:

- When you add an option that adds or updates a port value, such as the `OEM` option.
- When you add or remove an option group with an option that includes a port value.

In these cases, choose the **Apply Immediately** option in the console. Or you can include the `--apply-immediately` option when using the AWS CLI or set the `ApplyImmediately` parameter to `true` when

using the RDS API. Options that don't include port values can be applied immediately, or can be applied during the next maintenance window for the DB instance.

Note

If you specify a security group as a value for an option in an option group, you manage the security group by modifying the option group. You can't change or remove this security group by modifying a DB instance. Also, the security group doesn't appear in the DB instance details in the AWS Management Console or in the output for the AWS CLI command `describe-db-instances`.

Console

You can use the AWS Management Console to modify an option setting.

To modify an option setting by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Select the option group whose option that you want to modify, and then choose **Modify option**.
4. In the **Modify option** window, from **Installed Options**, choose the option whose setting you want to modify. Make the changes that you want.
5. To enable the option as soon as you add it, for **Apply Immediately**, choose **Yes**. If you choose **No** (the default), the option is enabled for each associated DB instance during its next maintenance window.
6. When the settings are as you want them, choose **Modify Option**.

AWS CLI

To modify an option setting, use the AWS CLI `add-option-to-option-group` command with the option group and option that you want to modify. By default, the option is enabled for each associated DB instance during its next maintenance window. To apply the change immediately to all associated DB instances, include the `--apply-immediately` parameter. To modify an option setting, use the `--settings` argument.

Example

The following example modifies the port that the Oracle Enterprise Manager Database Control (OEM) uses in an option group named `testoptiongroup` and immediately applies the change.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
--option-group-name testoptiongroup \
--options OptionName=OEM,Port=5432,DBSecurityGroupMemberships=default \
--apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
--option-group-name testoptiongroup ^
--options OptionName=OEM,Port=5432,DBSecurityGroupMemberships=default ^
--apply-immediately
```

Command output is similar to the following:

```
OPTIONGROUP  False  oracle-ee  12.1  arn:aws:rds:us-east-1:1234567890:og:testoptiongroup
  Test Option Group      testoptiongroup
OPTIONS Oracle 12c EM Express    OEM      False   False   5432
DBSECURITYGROUPMEMBERSHIPS    default  authorized
```

Example

The following example modifies the Oracle option NATIVE_NETWORK_ENCRYPTION and changes the option settings.

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
--option-group-name testoptiongroup \
--options '[{"OptionSettings": [{"Name": "SQLNET.ENCRYPTION_SERVER", "Value": "REQUIRED"}, {"Name": "SQLNET.ENCRYPTION_TYPES_SERVER", "Value": "AES256,AES192,DES,RC4_256"}], "OptionName": "NATIVE_NETWORK_ENCRYPTION"}]' \
--apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
--option-group-name testoptiongroup ^
--options "OptionSettings=[{ "Name": "SQLNET.ENCRYPTION_SERVER", "Value": "REQUIRED"}, { "Name": "SQLNET.ENCRYPTION_TYPES_SERVER", "Value": "AES256\,AES192\,DES\,RC4_256"}], "OptionName": "NATIVE_NETWORK_ENCRYPTION" ^
--apply-immediately
```

Command output is similar to the following:

```
OPTIONGROUP  False  oracle-ee  12.1  arn:aws:rds:us-east-1:1234567890:og:testoptiongroup
  Test Option Group      testoptiongroup
OPTIONS Oracle Advanced Security - Native Network Encryption      NATIVE_NETWORK_ENCRYPTION
  False   False
OPTIONSETTINGS
  RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40  STATIC
  STRING
    RC4_256,AES256,AES192,3DES168,RC4_128,AES128,3DES112,RC4_56,DES,RC4_40,DES40
    Specifies list of encryption algorithms in order of intended use
      True      True      SQLNET.ENCRYPTION_TYPES_SERVER      AES256,AES192,DES,RC4_256
OPTIONSETTINGS  ACCEPTED,REJECTED,REQUESTED,REQUIRED  STATIC  STRING  REQUESTED
  Specifies the desired encryption behavior  False      True      SQLNET.ENCRYPTION_SERVER
  REQUIRED
OPTIONSETTINGS  SHA1,MD5  STATIC  STRING  SHA1,MD5  Specifies list of
  checksumming algorithms in order of intended use  True      True
  SQLNET.CRYPTO_CHECKSUM_TYPES_SERVER  SHA1,MD5
OPTIONSETTINGS  ACCEPTED,REJECTED,REQUESTED,REQUIRED  STATIC  STRING
  REQUESTED  Specifies the desired data integrity behavior  False      True
  SQLNET.CRYPTO_CHECKSUM_SERVER  REQUESTED
```

RDS API

To modify an option setting, use the Amazon RDS API [ModifyOptionGroup](#) command with the option group and option that you want to modify. By default, the option is enabled for each associated DB instance during its next maintenance window. To apply the change immediately to all associated DB instances, include the `ApplyImmediately` parameter and set it to `true`.

Removing an option from an option group

Some options can be removed from an option group, and some cannot. A persistent option cannot be removed from an option group until all DB instances associated with that option group are disassociated. A permanent option can never be removed from an option group. For more information about what options are removable, see the documentation for your specific engine listed at [Working with option groups \(p. 212\)](#).

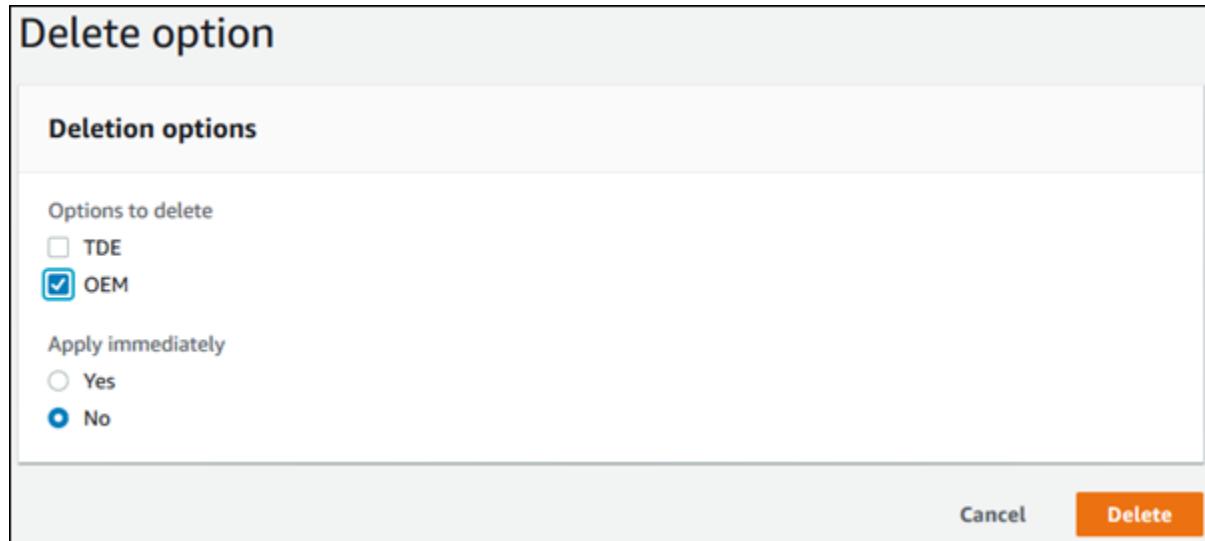

If you remove all options from an option group, Amazon RDS doesn't delete the option group. DB instances that are associated with the empty option group continue to be associated with it; they just won't have any active options. Alternatively, to remove all options from a DB instance, you can associate the DB instance with the default (empty) option group.

Console

You can use the AWS Management Console to remove an option from an option group.

To remove an option from an option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Select the option group whose option you want to remove, and then choose **Delete option**.
4. In the **Delete option** window, do the following:
 - Select the check box for the option that you want to delete.
 - For the deletion to take effect as soon as you make it, for **Apply immediately**, choose **Yes**. If you choose **No** (the default), the option is deleted for each associated DB instance during its next maintenance window.

- When the settings are as you want them, choose **Yes, Delete**.

AWS CLI

To remove an option from an option group, use the AWS CLI `remove-option-from-option-group` command with the option that you want to delete. By default, the option is removed from each associated DB instance during its next maintenance window. To apply the change immediately, include the `--apply-immediately` parameter.

Example

The following example removes the Oracle Enterprise Manager Database Control (OEM) option from an option group named `testoptiongroup` and immediately applies the change.

For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
--option-group-name testoptiongroup \
--options OEM \
--apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group ^
--option-group-name testoptiongroup ^
--options OEM ^
--apply-immediately
```

Command output is similar to the following:

```
OPTIONGROUP      testoptiongroup oracle-ee    12.1      Test option group
```

RDS API

To remove an option from an option group, use the Amazon RDS API `ModifyOptionGroup` action. By default, the option is removed from each associated DB instance during its next maintenance window. To apply the change immediately, include the `ApplyImmediately` parameter and set it to `true`.

Include the following parameters:

- `OptionGroupName`
- `OptionsToRemove.OptionName`

Deleting an option group

You can delete an option group that is not associated with any Amazon RDS resource. An option group can be associated with a DB instance, a manual DB snapshot, or an automated DB snapshot.

If you try to delete an option group that is associated with an Amazon RDS resource, an error similar to the following is returned.

An error occurred (InvalidOptionGroupStateFault) when calling the DeleteOptionGroup operation: The option group 'optionGroupName' cannot be deleted because it is in use.

To find the Amazon RDS resources associated with an option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the name of the option group to show its details.
4. Check the **Associated Instances and Snapshots** section for the associated Amazon RDS resources.

If a DB instance is associated with the option group, modify the DB instance to use a different option group. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

If a manual DB snapshot is associated with the option group, modify the DB snapshot to use a different option group using the AWS CLI `modify-db-snapshot` command.

Note

You can't modify the option group of an automated DB snapshot.

Console

One way of deleting an option group is by using the AWS Management Console.

To delete an option group by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group.
4. Choose **Delete group**.
5. On the confirmation page, choose **Delete** to finish deleting the option group, or choose **Cancel** to cancel the deletion.

AWS CLI

To delete an option group, use the AWS CLI `delete-option-group` command with the following required parameter.

- `--option-group-name`

Example

The following example deletes an option group named `testoptiongroup`.

For Linux, macOS, or Unix:

```
aws rds delete-option-group \
--option-group-name testoptiongroup
```

For Windows:

```
aws rds delete-option-group ^
--option-group-name testoptiongroup
```

RDS API

To delete an option group, call the Amazon RDS API [DeleteOptionGroup](#) operation. Include the following parameter:

- OptionGroupName

Working with DB parameter groups

You manage your DB engine configuration by associating your DB instances with parameter groups. Amazon RDS defines parameter groups with default settings that apply to newly created DB instances.

Important

You can define your own parameter groups with customized settings. Then you can modify your DB instances to use your own parameter groups.

For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

A *DB parameter group* acts as a container for engine configuration values that are applied to one or more DB instances.

If you create a DB instance without specifying a DB parameter group, the DB instance uses a default DB parameter group. Each default DB parameter group contains database engine defaults and Amazon RDS system defaults based on the engine, compute class, and allocated storage of the instance. You can't modify the parameter settings of a default parameter group. Instead, you create your own parameter group where you choose your own parameter settings. Not all DB engine parameters can be changed in a parameter group that you create.

If you want to use your own parameter group, you create a new parameter group and modify the parameters that you want to. You then modify your DB instance to use the new parameter group. If you update parameters within a DB parameter group, the changes apply to all DB instances that are associated with that parameter group.

You can copy an existing DB parameter group with the AWS CLI [copy-db-parameter-group](#) command. Copying a parameter group can be convenient when you want to include most of an existing DB parameter group's custom parameters and values in a new DB parameter group.

Here are some important points about working with parameters in a DB parameter group:

- When you change a dynamic parameter and save the DB parameter group, the change is applied immediately regardless of the **Apply Immediately** setting. When you change a static parameter and save the DB parameter group, the parameter change takes effect after you manually reboot the DB instance. You can reboot a DB instance using the RDS console, by calling the `reboot-db-instance` CLI command, or by calling the `RebootDbInstance` API operation. The requirement to reboot the associated DB instance after a static parameter change helps mitigate the risk of a parameter misconfiguration affecting an API call, such as calling `ModifyDBInstance` to change DB instance class or scale storage.

If a DB instance isn't using the latest changes to its associated DB parameter group, the AWS Management Console shows the DB parameter group with a status of **pending-reboot**. The **pending-reboot** parameter groups status doesn't result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.

- When you change the DB parameter group associated with a DB instance, you must manually reboot the instance before the DB instance can use the new DB parameter group. For more information about changing the DB parameter group, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).
- You can specify the value for a DB parameter as an integer or as an integer expression built from formulas, variables, functions, and operators. Functions can include a mathematical log expression. For more information, see [Specifying DB parameters \(p. 240\)](#).
- Set any parameters that relate to the character set or collation of your database in your parameter group before creating the DB instance and before you create a database in your DB instance. This ensures that the default database and new databases in your DB instance use the character set and collation values that you specify. If you change character set or collation parameters for your DB instance, the parameter changes are not applied to existing databases.

You can change character set or collation values for an existing database using the `ALTER DATABASE` command, for example:

```
ALTER DATABASE database_name CHARACTER SET character_set_name COLLATE collation;
```

- Improperly setting parameters in a DB parameter group can have unintended adverse effects, including degraded performance and system instability. Always exercise caution when modifying database parameters and back up your data before modifying a DB parameter group. Try out parameter group setting changes on a test DB instance before applying those parameter group changes to a production DB instance.
- To determine the supported parameters for your DB engine, you can view the parameters in the DB parameter group used by the DB instance. For more information, see [Viewing parameter values for a DB parameter group \(p. 239\)](#).

Creating a DB parameter group

You can create a new DB parameter group using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To create a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
The **Create parameter group** window appears.
4. In the **Parameter group family** list, select a DB parameter group family.
5. In the **Type** list, select **DB Parameter Group**.
6. In the **Group name** box, enter the name of the new DB parameter group.
7. In the **Description** box, enter a description for the new DB parameter group.
8. Choose **Create**.

AWS CLI

To create a DB parameter group, use the AWS CLI [create-db-parameter-group](#) command. The following example creates a DB parameter group named *mydbparametergroup* for MySQL version 5.6 with a description of "My new parameter group."

Include the following required parameters:

- `--db-parameter-group-name`
- `--db-parameter-group-family`
- `--description`

To list all of the available parameter group families, use the following command:

```
aws rds describe-db-engine-versions --query "DBEngineVersions[].DBParameterGroupFamily"
```

Note

The output contains duplicates.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \  
  --db-parameter-group-name mydbparametergroup \  
  --db-parameter-group-family MySQL5.6 \  
  --description "My new parameter group"
```

For Windows:

```
aws rds create-db-parameter-group ^  
  --db-parameter-group-name mydbparametergroup ^  
  --db-parameter-group-family MySQL5.6 ^  
  --description "My new parameter group"
```

This command produces output similar to the following:

```
DBPARAMETERGROUP  mydbparametergroup  mysql5.6  My new parameter group
```

RDS API

To create a DB parameter group, use the RDS API [CreateDBParameterGroup](#) operation.

Include the following required parameters:

- `DBParameterGroupName`
- `DBParameterGroupFamily`
- `Description`

Associating a DB parameter group with a DB instance

You can create your own DB parameter groups with customized settings. You can associate a DB parameter group with a DB instance using the AWS Management Console, the AWS CLI, or the RDS API. You can do so when you create or modify a DB instance.

For information about creating a DB parameter group, see [Creating a DB parameter group \(p. 229\)](#).

For information about creating a DB instance, see [Creating an Amazon RDS DB instance \(p. 141\)](#). For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

Note

When you change the DB parameter group associated with a DB instance, you must manually reboot the instance before the DB instance can use the new DB parameter group.

Console

To associate a DB parameter group with a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB Instance** page appears.
4. Change the **DB parameter group** setting.
5. Choose **Continue** and check the summary of modifications.
6. (Optional) Choose **Apply immediately** to apply the changes immediately. Choosing this option can cause an outage in some cases. For more information, see [Using the Apply Immediately setting \(p. 251\)](#).
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB instance** to save your changes.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To associate a DB parameter group with a DB instance, use the AWS CLI `modify-db-instance` command with the following options:

- `--db-instance-identifier`
- `--db-parameter-group-name`

The following example associates the `mydbpg` DB parameter group with the `database-1` DB instance. The changes are applied immediately by using `--apply-immediately`. Use `--no-apply-immediately` to apply the changes during the next maintenance window. For more information, see [Using the Apply Immediately setting \(p. 251\)](#).

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier database-1 \
```

```
--db-parameter-group-name mydbpg \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier database-1 ^
--db-parameter-group-name mydbpg ^
--apply-immediately
```

RDS API

To associate a DB parameter group with a DB instance, use the RDS API [ModifyDBInstance](#) operation with the following parameters:

- `DBInstanceName`
- `DBParameterGroupName`

Modifying parameters in a DB parameter group

You can modify parameter values in a customer-created DB parameter group; you can't change the parameter values in a default DB parameter group. Changes to parameters in a customer-created DB parameter group are applied to all DB instances that are associated with the DB parameter group.

Changes to some parameters are applied to the DB instance immediately without a reboot. Changes to other parameters are applied only after the DB instance is rebooted. The RDS console shows the status of the DB parameter group associated with a DB instance on the **Configuration** tab. For example, if the DB instance isn't using the latest changes to its associated DB parameter group, the RDS console shows the DB parameter group with a status of **pending-reboot**. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.

Configuration		Instance class
DB instance id	database-2	Instance class
Engine version	14.00.3281.6.v1	db.r4.large
DB name	-	vCPU
License model	License Included	RAM
Collation	SQL_Latin1_General_CI_AS	15.25 GB
Option groups	test-se-2017	Availability
ARN	arn:aws:rds:us-west-2:123456789012:db:database-2	Master username
Resource id	db-123456789012	admin
Created time	Wed Dec 04 2019 14:22:38 GMT-0500 (Eastern Standard Time)	IAM db authentication
Parameter group	test-sqlserver-se-2017 (pending-reboot)	Not Enabled
Deletion protection	Disabled	Multi AZ
		Yes (Mirroring)
		Secondary Zone
		us-west-2d

Console

To modify a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the parameter group that you want to modify.
4. For **Parameter group actions**, choose **Edit**.
5. Change the values of the parameters that you want to modify. You can scroll through the parameters using the arrow keys at the top right of the dialog box.

You can't change values in a default parameter group.
6. Choose **Save changes**.

AWS CLI

To modify a DB parameter group, use the AWS CLI `modify-db-parameter-group` command with the following required options:

- `--db-parameter-group-name`

- `--parameters`

The following example modifies the `max_connections` and `max_allowed_packet` values in the DB parameter group named `mydbparametergroup`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name mydbparametergroup \
    --parameters "ParameterName=max_connections,ParameterValue=250,ApplyMethod=immediate" \
    "ParameterName=max_allowed_packet,ParameterValue=1024,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
    --db-parameter-group-name mydbparametergroup ^
    --parameters "ParameterName=max_connections,ParameterValue=250,ApplyMethod=immediate" ^
    "ParameterName=max_allowed_packet,ParameterValue=1024,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBPARAMETERGROUP  mydbparametergroup
```

RDS API

To modify a DB parameter group, use the RDS API [ModifyDBParameterGroup](#) operation with the following required parameters:

- `DBParameterGroupName`
- `Parameters`

Resetting parameters in a DB parameter group to their default values

You can reset parameter values in a customer-created DB parameter group to their default values. Changes to parameters in a customer-created DB parameter group are applied to all DB instances that are associated with the DB parameter group.

When you use the console, you can reset specific parameters to their default values, but you can't easily reset all of the parameters in the DB parameter group at once. When you use the AWS CLI or RDS API, you can reset specific parameters to their default values, and you can reset all of the parameters in the DB parameter group at once.

Changes to some parameters are applied to the DB instance immediately without a reboot. Changes to other parameters are applied only after the DB instance is rebooted. The RDS console shows the status of the DB parameter group associated with a DB instance on the **Configuration** tab. For example, if the DB instance isn't using the latest changes to its associated DB parameter group, the RDS console shows the DB parameter group with a status of **pending-reboot**. To apply the latest parameter changes to that DB instance, manually reboot the DB instance.

The screenshot shows the 'Configuration' tab selected in the top navigation bar. The main content area is titled 'Instance' and contains two columns of configuration details.

Configuration	Instance class
DB instance id database-2	Instance class db.r4.large
Engine version 14.00.3281.6.v1	vCPU 2
DB name -	RAM 15.25 GB
License model License Included	Availability
Collation SQL_Latin1_General_CI_AS	Master username admin
Option groups test-se-2017	IAM db authentication Not Enabled
ARN arn:aws:rds:us-west-2:123456789012:db:database-2	Multi AZ Yes (Mirroring)
Resource id db-12345678	Secondary Zone us-west-2d
Created time Wed Dec 04 2019 14:22:38 GMT-0500 (Eastern Standard Time)	
Parameter group test-sqlserver-se-2017 (pending-reboot)	
Deletion protection Disabled	

Note

In a default DB parameter group, parameters are always set to their default values.

Console

To reset parameters in a DB parameter group to their default values

- Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
 - In the navigation pane, choose **Parameter groups**.
 - In the list, choose the parameter group.
 - For **Parameter group actions**, choose **Edit**.
 - Choose the parameters that you want to reset to their default values. You can scroll through the parameters using the arrow keys at the top right of the dialog box.
- You can't reset values in a default parameter group.
- Choose **Reset** and then confirm by choosing **Reset parameters**.

AWS CLI

To reset some or all of the parameters in a DB parameter group, use the AWS CLI `reset-db-parameter-group` command with the following required option: `--db-parameter-group-name`.

To reset all of the parameters in the DB parameter group, specify the `--reset-all-parameters` option. To reset specific parameters, specify the `--parameters` option.

The following example resets all of the parameters in the DB parameter group named `mydbparametergroup` to their default values.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-parameter-group \
    --db-parameter-group-name mydbparametergroup \
    --reset-all-parameters
```

For Windows:

```
aws rds reset-db-parameter-group ^
    --db-parameter-group-name mydbparametergroup ^
    --reset-all-parameters
```

The following example resets the `max_connections` and `max_allowed_packet` options to their default values in the DB parameter group named `mydbparametergroup`.

Example

For Linux, macOS, or Unix:

```
aws rds reset-db-parameter-group \
    --db-parameter-group-name mydbparametergroup \
    --parameters "ParameterName=max_connections,ApplyMethod=immediate" \
        "ParameterName=max_allowed_packet,ApplyMethod=immediate"
```

For Windows:

```
aws rds reset-db-parameter-group ^
    --db-parameter-group-name mydbparametergroup ^
    --parameters "ParameterName=max_connections,ApplyMethod=immediate" ^
        "ParameterName=max_allowed_packet,ApplyMethod=immediate"
```

The command produces output like the following:

```
DBParameterGroupName mydbparametergroup
```

RDS API

To reset parameters in a DB parameter group to their default values, use the RDS API `ResetDBParameterGroup` command with the following required parameter: `DBParameterGroupName`.

To reset all of the parameters in the DB parameter group, set the `ResetAllParameters` parameter to `true`. To reset specific parameters, specify the `Parameters` parameter.

Copying a DB parameter group

You can copy custom DB parameter groups that you create. Copying a parameter group is a convenient solution when you have already created a DB parameter group and you want to include most of the

custom parameters and values from that group in a new DB parameter group. You can copy a DB parameter group by using the AWS Management Console, the AWS CLI [copy-db-parameter-group](#) command, or the RDS API [CopyDBParameterGroup](#) operation.

After you copy a DB parameter group, wait at least 5 minutes before creating your first DB instance that uses that DB parameter group as the default parameter group. Doing this allows Amazon RDS to fully complete the copy action before the parameter group is used. This is especially important for parameters that are critical when creating the default database for a DB instance. An example is the character set for the default database defined by the `character_set_database` parameter. Use the **Parameter Groups** option of the [Amazon RDS console](#) or the [describe-db-parameters](#) command to verify that your DB parameter group is created.

Note

You can't copy a default parameter group. However, you can create a new parameter group that is based on a default parameter group.

Currently, you can't copy a parameter group to a different AWS Region.

Console

To copy a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the custom parameter group that you want to copy.
4. For **Parameter group actions**, choose **Copy**.
5. In **New DB parameter group identifier**, enter a name for the new parameter group.
6. In **Description**, enter a description for the new parameter group.
7. Choose **Copy**.

AWS CLI

To copy a DB parameter group, use the AWS CLI [copy-db-parameter-group](#) command with the following required options:

- `--source-db-parameter-group-identifier`
- `--target-db-parameter-group-identifier`
- `--target-db-parameter-group-description`

The following example creates a new DB parameter group named `mygroup2` that is a copy of the DB parameter group `mygroup1`.

Example

For Linux, macOS, or Unix:

```
aws rds copy-db-parameter-group \
--source-db-parameter-group-identifier mygroup1 \
--target-db-parameter-group-identifier mygroup2 \
--target-db-parameter-group-description "DB parameter group 2"
```

For Windows:

```
aws rds copy-db-parameter-group ^
--source-db-parameter-group-identifier mygroup1 ^
```

```
--target-db-parameter-group-identifier mygroup2 ^
--target-db-parameter-group-description "DB parameter group 2"
```

RDS API

To copy a DB parameter group, use the RDS API [CopyDBParameterGroup](#) operation with the following required parameters:

- `SourceDBParameterGroupIdentifier`
- `TargetDBParameterGroupIdentifier`
- `TargetDBParameterGroupDescription`

Listing DB parameter groups

You can list the DB parameter groups you've created for your AWS account.

Note

Default parameter groups are automatically created from a default parameter template when you create a DB instance for a particular DB engine and version. These default parameter groups contain preferred parameter settings and can't be modified. When you create a custom parameter group, you can modify parameter settings.

Console

To list all DB parameter groups for an AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.

The DB parameter groups appear in a list.

AWS CLI

To list all DB parameter groups for an AWS account, use the AWS CLI [describe-db-parameter-groups](#) command.

Example

The following example lists all available DB parameter groups for an AWS account.

```
aws rds describe-db-parameter-groups
```

The command returns a response like the following:

```
DBPARAMETERGROUP  default.mysql5.5      mysql5.5  Default parameter group for MySQL5.5
DBPARAMETERGROUP  default.mysql5.6      mysql5.6  Default parameter group for MySQL5.6
DBPARAMETERGROUP  mydbparametergroup    mysql5.6  My new parameter group
```

The following example describes the *mydbparamgroup1* parameter group.

For Linux, macOS, or Unix:

```
aws rds describe-db-parameter-groups \
```

```
--db-parameter-group-name mydbparamgroup1
```

For Windows:

```
aws rds describe-db-parameter-groups ^
--db-parameter-group-name mydbparamgroup1
```

The command returns a response like the following:

```
DBPARAMETERGROUP mydbparametergroup1 mysql5.5 My new parameter group
```

RDS API

To list all DB parameter groups for an AWS account, use the RDS API [DescribeDBParameterGroups](#) operation.

Viewing parameter values for a DB parameter group

You can get a list of all parameters in a DB parameter group and their values.

Console

To view the parameter values for a DB parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
The DB parameter groups appear in a list.
3. Choose the name of the parameter group to see its list of parameters.

AWS CLI

To view the parameter values for a DB parameter group, use the AWS CLI [describe-db-parameters](#) command with the following required parameter.

- `--db-parameter-group-name`

Example

The following example lists the parameters and parameter values for a DB parameter group named `mydbparametergroup`.

```
aws rds describe-db-parameters --db-parameter-group-name mydbparametergroup
```

The command returns a response like the following:

DBPARAMETER Type	Parameter Name	Parameter Value	Source	Data Type	Apply
DBPARAMETER Is Modifiable					
DBPARAMETER	allow-suspicious-udfs		engine-default	boolean	static
	false				
DBPARAMETER	auto_increment_increment		engine-default	integer	dynamic
	true				
DBPARAMETER	auto_increment_offset		engine-default	integer	dynamic
	true				

DBPARAMETER	binlog_cache_size	32768	system	integer	dynamic
DBPARAMETER	socket	/tmp/mysql.sock	system	string	static

RDS API

To view the parameter values for a DB parameter group, use the RDS API [DescribeDBParameters](#) command with the following required parameter.

- `DBParameterGroupName`

Comparing DB parameter groups

You can use the AWS Management Console to view the differences between two parameter groups for the same DB engine and version.

To compare two parameter groups

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. In the list, choose the two parameter groups that you want to compare.
4. For **Parameter group actions**, choose **Compare**.

Note

If the items you selected aren't equivalent, you can't choose **Compare**. For example, you can't compare a MySQL 5.6 and a MySQL 5.7 parameter group. You can't compare a DB parameter group and an Aurora DB cluster parameter group.

Specifying DB parameters

DB parameter types include the following:

- integer
- Boolean
- string
- long
- double
- timestamp
- object of other defined data types
- array of values of type integer, Boolean, string, long, double, timestamp, or object

You can also specify integer and Boolean DB parameters using expressions, formulas, and functions.

For the Oracle engine, you can use the `DBInstanceClassHugePagesDefault` formula variable to specify a Boolean DB parameter. See [DB parameter formula variables \(p. 241\)](#).

For the PostgreSQL engine, you can use an expression to specify a Boolean DB parameter. See [Boolean DB parameter expressions \(p. 243\)](#).

Contents

- [DB parameter formulas \(p. 241\)](#)
 - [DB parameter formula variables \(p. 241\)](#)
 - [DB parameter formula operators \(p. 241\)](#)
- [DB parameter functions \(p. 242\)](#)
- [Boolean DB parameter expressions \(p. 243\)](#)
- [DB parameter log expressions \(p. 244\)](#)
- [DB parameter value examples \(p. 244\)](#)

DB parameter formulas

A DB parameter formula is an expression that resolves to an integer value or a Boolean value. You enclose the expression in braces: {}. You can use a formula for either a DB parameter value or as an argument to a DB parameter function.

Syntax

```
{FormulaVariable}  
{FormulaVariable*Integer}  
{FormulaVariable*Integer/Integer}  
{FormulaVariable/Integer}
```

DB parameter formula variables

Each formula variable returns an integer or a Boolean value. The names of the variables are case-sensitive.

AllocatedStorage

Returns an integer representing the size, in bytes, of the data volume.

DBInstanceClassHugePagesDefault

Returns a Boolean value. Currently, it's only supported for Oracle engines.

For more information, see [Enabling HugePages for an Oracle DB instance \(p. 1101\)](#).

DBInstanceClassMemory

Returns an integer of the number of bytes of memory allocated to the DB instance class associated with the current DB instance, less the memory used by RDS processes that manage the instance.

DBInstanceVCPU

Returns an integer representing the number of virtual central processing units (vCPUs) used by Amazon RDS to manage the instance. Currently, it's only supported for the PostgreSQL engine.

EndPointPort

Returns an integer representing the port used when connecting to the DB instance.

DB parameter formula operators

DB parameter formulas support two operators: division and multiplication.

Division operator: /

Divides the dividend by the divisor, returning an integer quotient. Decimals in the quotient are truncated, not rounded.

Syntax

```
dividend / divisor
```

The dividend and divisor arguments must be integer expressions.

Multiplication operator: *

Multiplies the expressions, returning the product of the expressions. Decimals in the expressions are truncated, not rounded.

Syntax

```
expression * expression
```

Both expressions must be integers.

DB parameter functions

You specify the arguments of DB parameter functions as either integers or formulas. Each function must have at least one argument. Specify multiple arguments as a comma-separated list. The list can't have any empty members, such as *argument1,,argument3*. Function names are case-insensitive.

IF

Returns an argument.

Currently, it's only supported for Oracle engines, and the only supported first argument is {DBInstanceClassHugePagesDefault}. For more information, see [Enabling HugePages for an Oracle DB instance \(p. 1101\)](#).

Syntax

```
IF(argument1, argument2, argument3)
```

Returns the second argument if the first argument evaluates to true. Returns the third argument otherwise.

GREATEST

Returns the largest value from a list of integers or parameter formulas.

Syntax

```
GREATEST(argument1, argument2,...argumentn)
```

Returns an integer.

LEAST

Returns the smallest value from a list of integers or parameter formulas.

Syntax

```
LEAST(argument1, argument2,...argumentn)
```

Returns an integer.

SUM

Adds the values of the specified integers or parameter formulas.

Syntax

```
SUM(argument1, argument2,...argumentn)
```

Returns an integer.

Boolean DB parameter expressions

A Boolean DB parameter expression resolves to a Boolean value of 1 or 0. The expression is enclosed in quotation marks.

Note

Boolean DB parameter expressions are only supported for the PostgreSQL engine.

Syntax

```
"expression operator expression"
```

Both expressions must resolve to integers. An expression can be the following:

- integer constant
- DB parameter formula
- DB parameter function
- DB parameter variable

Boolean DB parameter expressions support the following inequality operators:

The greater than operator: >

Syntax

```
"expression > expression"
```

The less than operator: <

Syntax

```
"expression < expression"
```

The greater than or equal to operators: >=, =>

Syntax

```
"expression >= expression"  
"expression => expression"
```

The less than or equal to operators: <=, =<

Syntax

```
"expression <= expression"
```

```
"expression =< expression"
```

Example using a Boolean DB parameter expression

The following Boolean DB parameter expression example compares the result of a parameter formula with an integer to modify the Boolean DB parameter `wal_compression` for a PostgreSQL DB instance. The parameter expression compares the number of vCPUs with the value 2. If the number of vCPUs is greater than 2, then the `wal_compression` DB parameter is set to true.

```
aws rds modify-db-parameter-group --db-parameter-group-name group-name \  
--parameters "ParameterName=wal_compression,ParameterValue=\\"{DBInstanceVCPU} > 2\\" "
```

DB parameter log expressions

You can set an integer DB parameter value to a log expression. You enclose the expression in braces: {}.

For example:

```
{log(DBInstanceClassMemory/8187281418)*1000}
```

The `log` function represents log base 2. This example also uses the `DBInstanceClassMemory` formula variable. See [DB parameter formula variables \(p. 241\)](#).

Note

Currently, you can't specify the MySQL `innodb_log_file_size` parameter with any value other than an integer.

DB parameter value examples

These examples show using formulas, functions, and expressions for the values of DB parameters.

Note

DB Parameter functions are currently supported only in the console and aren't supported in the AWS CLI.

Warning

Improperly setting parameters in a DB parameter group can have unintended adverse effects. These might include degraded performance and system instability. Use caution when modifying database parameters and back up your data before modifying your DB parameter group. Try out parameter group changes on a test DB instance, created using point-in-time-restores, before applying those parameter group changes to your production DB instances.

Example using the DB parameter function GREATEST

You can specify the `GREATEST` function in an Oracle processes parameter. Use it to set the number of user processes to the larger of either 80 or `DBInstanceClassMemory` divided by 9,868,951.

```
GREATEST({DBInstanceClassMemory/9868951},80)
```

Example using the DB parameter function LEAST

You can specify the `LEAST` function in a MySQL `max_binlog_cache_size` parameter value. Use it to set the maximum cache size a transaction can use in a MySQL instance to the lesser of 1 MB or `DBInstanceClass/256`.

```
LEAST({DBInstanceClassMemory/256},10485760)
```

Managing an Amazon RDS DB instance

Following, you can find instructions for managing and maintaining your Amazon RDS DB instance.

Topics

- [Stopping an Amazon RDS DB instance temporarily \(p. 246\)](#)
- [Starting an Amazon RDS DB instance that was previously stopped \(p. 249\)](#)

Stopping an Amazon RDS DB instance temporarily

If you use a DB instance intermittently, for temporary testing, or for a daily development activity, you can stop your Amazon RDS DB instance temporarily to save money. While your DB instance is stopped, you are charged for provisioned storage (including Provisioned IOPS) and backup storage (including manual snapshots and automated backups within your specified retention window), but not for DB instance hours. For more information, see [Billing FAQs](#).

Note

In some cases, a large amount of time is required to stop a DB instance. If you want to stop your DB instance and restart it immediately, you can reboot the DB instance. For information about rebooting a DB instance, see [Rebooting a DB instance \(p. 276\)](#).

You can stop and start DB instances that are running the following engines:

- MariaDB
- Microsoft SQL Server
- MySQL
- Oracle
- PostgreSQL

Stopping and starting a DB instance is supported for all DB instance classes, and in all AWS Regions.

You can stop and start a DB instance whether it is configured for a single Availability Zone or for Multi-AZ, for database engines that support Multi-AZ deployments. You can't stop an Amazon RDS for SQL Server DB instance in a Multi-AZ configuration.

Note

For a Multi-AZ deployment, a large amount of time might be required to stop a DB instance.

If you have at least one backup after a previous failover, then you can speed up the stop DB instance operation by performing a reboot with failover operation before stopping the DB instance.

When you stop a DB instance, the DB instance performs a normal shutdown and stops running. The status of the DB instance changes to **stopping** and then **stopped**. Any storage volumes remain attached to the DB instance, and their data is kept. Any data stored in the RAM of the DB instance is deleted.

Stopping a DB instance removes pending actions, except for pending actions for the DB instance's option group or DB parameter group.

Automated backups aren't created while a DB instance is stopped. Backups can be retained longer than the backup retention period if a DB instance has been stopped. RDS doesn't include time spent in the stopped state when the backup retention window is calculated.

Important

You can stop a DB instance for up to seven days. If you don't manually start your DB instance after seven days, your DB instance is automatically started so that it doesn't fall behind any required maintenance updates.

Benefits

Stopping and starting a DB instance is faster than creating a DB snapshot, and then restoring the snapshot.

When you stop a DB instance it retains its ID, Domain Name Server (DNS) endpoint, parameter group, security group, and option group. When you start a DB instance, it has the same configuration as when

you stopped it. In addition, if you stop a DB instance, Amazon RDS retains the Amazon Simple Storage Service (Amazon S3) transaction logs so you can do a point-in-time restore if necessary.

Limitations

The following are some limitations to stopping and starting a DB instance:

- You can't stop a DB instance that has a read replica, or that is a read replica.
- You can't stop an Amazon RDS for SQL Server DB instance in a Multi-AZ configuration.
- You can't modify a stopped DB instance.
- You can't delete an option group that is associated with a stopped DB instance.
- You can't delete a DB parameter group that is associated with a stopped DB instance.

Option and parameter group considerations

You can't remove persistent options (including permanent options) from an option group if there are DB instances associated with that option group. This functionality is also true of any DB instance with a state of stopping, stopped, or starting.

You can change the option group or DB parameter group that is associated with a stopped DB instance, but the change does not occur until the next time you start the DB instance. If you chose to apply changes immediately, the change occurs when you start the DB instance. Otherwise the change occurs during the next maintenance window after you start the DB instance.

Public IP address

When you stop a DB instance, it retains its DNS endpoint. If you stop a DB instance that has a public IP address, Amazon RDS releases its public IP address. When the DB instance is restarted, it has a different public IP address.

Note

You should always connect to a DB instance using the DNS endpoint, not the IP address.

Stopping a DB instance temporarily

You can stop a DB using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To stop a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to stop.
3. For **Actions**, choose **Stop**.
4. (Optional) In the **Stop DB Instance** window, choose **Yes** for **Create Snapshot?** and enter the snapshot name for **Snapshot name**. Choose **Yes** if you want to create a snapshot of the DB instance before stopping it.
5. Choose **Yes, Stop Now** to stop the DB instance, or choose **Cancel** to cancel the operation.

AWS CLI

To stop a DB instance by using the AWS CLI, call the `stop-db-instance` command with the following option:

- `--db-instance-identifier` – the name of the DB instance.

Example

```
aws rds stop-db-instance --db-instance-identifier mydbinstance
```

RDS API

To stop a DB instance by using the Amazon RDS API, call the [StopDBInstance](#) operation with the following parameter:

- `DBInstanceIdentifier` – the name of the DB instance.

Starting an Amazon RDS DB instance that was previously stopped

You can stop your Amazon RDS DB instance temporarily to save money. After you stop your DB instance, you can restart it to begin using it again. For more details about stopping and starting DB instances, see [Stopping an Amazon RDS DB instance temporarily \(p. 246\)](#).

When you start a DB instance that you previously stopped, the DB instance retains the ID, Domain Name Server (DNS) endpoint, parameter group, security group, and option group. When you start a stopped instance, you are charged a full instance hour.

Console

To start a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to start.
3. For **Actions**, choose **Start**.

AWS CLI

To start a DB instance by using the AWS CLI, call the `start-db-instance` command with the following option:

- `--db-instance-identifier` – The name of the DB instance.

Example

```
aws rds start-db-instance --db-instance-identifier mydbinstance
```

RDS API

To start a DB instance by using the Amazon RDS API, call the `StartDBInstance` operation with the following parameter:

- `DBInstanceIdentifier` – The name of the DB instance.

Modifying an Amazon RDS DB instance

You can change the settings of a DB instance to accomplish tasks such as adding additional storage or changing the DB instance class. In this topic, you can find out how to modify an Amazon RDS DB instance and learn about the settings for DB instances.

We recommend that you test any changes on a test instance before modifying a production instance, so that you fully understand the impact of each change. Testing is especially important when upgrading database versions.

Most modifications to a DB instance you can either apply immediately or defer until the next maintenance window. Some modifications, such as parameter group changes, require that you manually reboot your DB instance for the change to take effect.

Important

Some modifications result in downtime because Amazon RDS must reboot your DB instance for the change to take effect. Review the impact to your database and applications before modifying your DB instance settings.

Console

To modify a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB Instance** page appears.
4. Change any of the settings that you want. For information about each setting, see [Settings for DB instances \(p. 251\)](#).
5. When all the changes are as you want them, choose **Continue** and check the summary of modifications.
6. (Optional) Choose **Apply immediately** to apply the changes immediately. Choosing this option can cause downtime in some cases. For more information, see [Using the Apply Immediately setting \(p. 251\)](#).
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** to save your changes.

Or choose **Back** to edit your changes or **Cancel** to cancel your changes.

AWS CLI

To modify a DB instance by using the AWS CLI, call the `modify-db-instance` command. Specify the DB instance identifier and the values for the options that you want to modify. For information about each option, see [Settings for DB instances \(p. 251\)](#).

Example

The following code modifies `mydbinstance` by setting the backup retention period to 1 week (7 days). The code enables deletion protection by using `--deletion-protection`. To disable deletion protection, use `--no-deletion-protection`. The changes are applied during the next maintenance window by using `--no-apply-immediately`. Use `--apply-immediately` to apply the changes immediately. For more information, see [Using the Apply Immediately setting \(p. 251\)](#).

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--backup-retention-period 7 \
--deletion-protection \
--no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--backup-retention-period 7 ^
--deletion-protection ^
--no-apply-immediately
```

RDS API

To modify a DB instance by using the Amazon RDS API, call the [ModifyDBInstance](#) operation. Specify the DB instance identifier, and the parameters for the settings that you want to modify. For information about each parameter, see [Settings for DB instances \(p. 251\)](#).

Using the Apply Immediately setting

When you modify a DB instance, you can apply the changes immediately. To apply changes immediately, you choose the **Apply Immediately** option in the AWS Management Console. Or you use the `--apply-immediately` parameter when calling the AWS CLI or set the `ApplyImmediately` parameter to `true` when using the Amazon RDS API.

If you don't choose to apply changes immediately, the changes are put into the pending modifications queue. During the next maintenance window, any pending changes in the queue are applied. If you choose to apply changes immediately, your new changes and any changes in the pending modifications queue are applied.

Important

If any of the pending modifications require the DB instance to be temporarily unavailable (*downtime*), choosing the apply immediately option can cause unexpected downtime.

When you choose to apply a change immediately, any pending modifications are also applied immediately, instead of during the next maintenance window.

If you don't want a pending change to be applied in the next maintenance window, you can modify the DB instance to revert the change. You can do this by using the AWS CLI and specifying the `--apply-immediately` option.

Changes to some database settings are applied immediately, even if you choose to defer your changes. To see how the different database settings interact with the apply immediately setting, see [Settings for DB instances \(p. 251\)](#).

Settings for DB instances

In the following table, you can find details about which settings you can and can't modify, when changes can be applied, and whether the changes cause downtime for your DB instance.

You can modify a DB instance using the console, the `modify-db-instance` CLI command, or the [ModifyDBInstance](#) RDS API operation.

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
Allocated storage The storage, in gibibytes, that you want to allocate for your DB instance. You can only increase the allocated storage. You can't reduce the allocated storage. You can't modify the storage of some older DB instances, or DB instances restored from older DB snapshots. The Allocated storage setting is disabled in the console if your DB instance isn't eligible. You can check whether you can allocate more storage by using the CLI command describe-valid-db-instance-modifications . This command returns the valid storage options for your DB instance. You can't modify allocated storage if the DB instance status is storage-optimization or if the allocated storage for the DB instance has been modified in the last six hours. The maximum storage allowed depends on your DB engine and the storage type. For more information, see Amazon RDS DB instance storage (p. 40) .	CLI option: <code>--allocated-storage</code> RDS API parameter: <code>AllocatedStorage</code>	If you choose to apply the change immediately, it occurs immediately. RDS API parameter: <code>AllocatedStorage</code> If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime doesn't occur during this change. Performance might be degraded during the change.	All DB engines
Auto minor version upgrade Yes to enable your DB instance to receive preferred minor DB engine version upgrades automatically when they become available. Amazon RDS performs automatic minor version upgrades in the maintenance window. Otherwise, No. For more information, see Automatically upgrading the minor engine version (p. 273) .	CLI option: <code>--auto-minor-version-upgrade --no-auto-minor-version-upgrade</code> RDS API parameter: <code>AutoMinorVersionUpgrade</code>	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	Only MariaDB, MySQL, Oracle, and PostgreSQL
Backup retention period	CLI option:	If you choose to apply the change	Downtime occurs if you change from 0 to a nonzero value,	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
<p>The number of days that automatic backups are retained. To disable automatic backups, set the backup retention period to 0.</p> <p>For more information, see Working with backups (p. 328).</p> <p>Note If you use AWS Backup to manage your backups, this option doesn't appear. For information about AWS Backup, see the AWS Backup Developer Guide.</p>	CLI option: <code>--backup-retention-period</code> RDS API parameter: <code>BackupRetentionPeriod</code>	immediately, it occurs immediately. If you don't choose to apply the change immediately, and you change the setting from a nonzero value to another nonzero value, the change is applied asynchronously, as soon as possible. Otherwise, the change occurs during the next maintenance window.	or from a nonzero value to 0. This applies to both Single-AZ and Multi-AZ DB instances.	
<p>Backup window</p> <p>The time range during which automated backups of your databases occur. The backup window is a start time in Universal Coordinated Time (UTC), and a duration in hours.</p> <p>For more information, see Working with backups (p. 328).</p> <p>Note If you use AWS Backup to manage your backups, this option doesn't appear. For information about AWS Backup, see the AWS Backup Developer Guide.</p>	CLI option: <code>--preferred-backup-window</code> RDS API parameter: <code>PreferredBackupWindow</code>	The change is applied asynchronously, as soon as possible.	Downtime doesn't occur during this change.	All DB engines
<p>Certificate authority</p> <p>The certificate that you want to use for SSL/TLS connections.</p> <p>For more information, see Using SSL/TLS to encrypt a connection to a DB instance (p. 1634).</p>	CLI option: <code>--ca-certificate-identifier</code> RDS API parameter: <code>CACertificateIdentifier</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime occurs during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
Copy tags to snapshots <p>If you have any DB instance tags, enable this option to copy them when you create a DB snapshot.</p> <p>For more information, see Tagging Amazon RDS resources (p. 299).</p>	CLI option: <code>--copy-tags-to-snapshot</code> or <code>--no-copy-tags-to-snapshot</code> RDS API parameter: <code>CopyTagsToSnapshot</code>	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines
Database port <p>The port that you want to use to access the DB instance.</p> <p>The port value must not match any of the port values specified for options in the option group that is associated with the DB instance.</p> <p>For more information, see Connecting to an Amazon RDS DB instance (p. 162).</p>	CLI option: <code>--db-port-number</code> RDS API parameter: <code>DBPortNumber</code>	The change occurs immediately. This setting ignores the apply immediately setting.	The DB instance is rebooted immediately.	All DB engines
DB engine version <p>The version of the DB engine that you want to use. Before you upgrade your production DB instance, we recommend that you test the upgrade process on a test DB instance to verify its duration and to validate your applications.</p> <p>For more information, see Upgrading a DB instance engine version (p. 271).</p>	CLI option: <code>--engine-version</code> RDS API parameter: <code>EngineVersion</code>	<p>If you choose to apply the change immediately, it occurs immediately.</p> <p>If you don't choose to apply the change immediately, it occurs during the next maintenance window.</p>	Downtime occurs during this change.	All DB engines
DB instance class <p>The DB instance class that you want to use.</p> <p>For more information, see DB instance classes (p. 7).</p>	CLI option: <code>--db-instance-class</code> RDS API parameter: <code>DBInstanceClass</code>	<p>If you choose to apply the change immediately, it occurs immediately.</p> <p>If you don't choose to apply the change immediately, it occurs during the next maintenance window.</p>	Downtime occurs during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
DB instance identifier The new DB instance identifier. This value is stored as a lowercase string. For more information about the effects of renaming a DB instance, see Renaming a DB instance (p. 274) .	CLI option: <code>--new-db-instance-identifier</code> RDS API parameter: <code>NewDBInstanceIdentifier</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime occurs during this change.	All DB engines
DB parameter group The DB parameter group that you want associated with the DB instance. For more information, see Working with DB parameter groups (p. 228) .	CLI option: <code>--db-parameter-group-name</code> RDS API parameter: <code>DBParameterGroupName</code>	The parameter group change occurs immediately.	Downtime doesn't occur during this change. However, you must manually reboot the DB instance before the new DB parameter group is used by the DB instance. For more information, see Working with DB parameter groups (p. 228) and Rebooting a DB instance (p. 276) .	All DB engines
Deletion protection Enable deletion protection to prevent your DB instance from being deleted. For more information, see Deleting a DB instance (p. 324) .	CLI option: <code>--deletion-protection --no-deletion-protection</code> RDS API parameter: <code>DeletionProtection</code>	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines
Enhanced Monitoring Enable Enhanced Monitoring to enable gathering metrics in real time for the operating system that your DB instance runs on. For more information, see Using Enhanced Monitoring (p. 471) .	CLI option: <code>--monitoring-interval and --monitoring-role-arn</code> RDS API parameter: <code>MonitoringInterval</code> and <code>MonitoringRoleArn</code>	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
IAM DB authentication Enable IAM DB authentication to authenticate database users through IAM users and roles. For more information, see IAM database authentication for MySQL and PostgreSQL (p. 1660) .	CLI option: <code>--enable-iam-database-authentication --no-enable-iam-database-authentication</code> RDS API parameter: <code>EnableIAMDatabaseAuthentication</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime doesn't occur during this change.	Only MySQL and PostgreSQL
Kerberos authentication Choose the Active Directory to move the DB instance to. The directory must exist prior to this operation. If a directory is already selected, you can specify None to remove the DB instance from its current directory. For more information, see Kerberos authentication (p. 1629) .	CLI option: <code>--domain and --domain-iam-role-name</code> RDS API parameter: <code>Domain and DomainIAMRoleName</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	A brief downtime occurs during this change.	Only Microsoft SQL Server, MySQL, Oracle, and PostgreSQL
License model Choose bring-your-own-license to use your license for Oracle. Choose license-included to use the general license agreement for Microsoft SQL Server or Oracle. For more information, see Licensing Microsoft SQL Server on Amazon RDS (p. 655) and Oracle licensing options (p. 990) .	CLI option: <code>--license-model</code> RDS API parameter: <code>LicenseModel</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime occurs during this change.	Only Microsoft SQL Server and Oracle
Log exports The types of database log files to publish to Amazon CloudWatch Logs. For more information, see Publishing database logs to Amazon CloudWatch Logs (p. 506) .	CLI option: <code>--cloudwatch-logs-export-configuration</code> RDS API parameter: <code>CloudwatchLogsExportConfiguration</code>	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
<p>Maintenance window</p> <p>The time range during which system maintenance occurs. System maintenance includes upgrades, if applicable. The maintenance window is a start time in Universal Coordinated Time (UTC), and a duration in hours.</p> <p>If you set the window to the current time, there must be at least 30 minutes between the current time and the end of the window to ensure that any pending changes are applied.</p> <p>For more information, see The Amazon RDS maintenance window (p. 268).</p>	<p>CLI option: <code>--preferred-maintenance-window</code></p> <p>RDS API parameter: <code>PreferredMaintenanceWindow</code></p>	<p>The change occurs immediately. This setting ignores the apply immediately setting.</p>	<p>If there are one or more pending actions that cause downtime, and the maintenance window is changed to include the current time, those pending actions are applied immediately and downtime occurs.</p>	All DB engines
<p>Multi-AZ deployment</p> <p>Yes to deploy your DB instance in multiple Availability Zones. Otherwise, No.</p> <p>For more information, see High availability (Multi-AZ) for Amazon RDS (p. 53).</p>	<p>CLI option: <code>--multi-az --no-multi-az</code></p> <p>RDS API parameter: <code>MultiAZ</code></p>	<p>If you choose to apply the change immediately, it occurs immediately.</p> <p>If you don't choose to apply the change immediately, it occurs during the next maintenance window.</p>	Downtime doesn't occur during this change.	All DB engines
<p>New master password</p> <p>The password for your master user. The password must contain 8–41 alphanumeric characters.</p>	<p>CLI option: <code>--master-user-password</code></p> <p>RDS API parameter: <code>MasterUserPassword</code></p>	<p>The change is applied asynchronously, as soon as possible. This setting ignores the apply immediately setting.</p>	Downtime doesn't occur during this change.	All DB engines
<p>Option group</p> <p>The option group that you want associated with the DB instance.</p> <p>For more information, see Working with option groups (p. 212).</p>	<p>CLI option: <code>--option-group-name</code></p> <p>RDS API parameter: <code>OptionGroupName</code></p>	<p>If you choose to apply the change immediately, it occurs immediately.</p> <p>If you don't choose to apply the change immediately, it occurs during the next maintenance window.</p>	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
Performance Insights Enable Performance Insights to monitor your DB instance load so that you can analyze and troubleshoot your database performance. Performance Insights isn't available for some DB engine versions and DB instance classes. The Performance Insights section doesn't appear in the console if it isn't available for your DB instance. For more information, see Using Performance Insights on Amazon RDS (p. 412) .	CLI option: <code>--enable-performance-insights --no-enable-performance-insights</code> RDS API parameter: <code>EnablePerformanceInsights</code>	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines
Performance Insights Master key The AWS KMS key identifier for the customer master key (CMK) for encryption of Performance Insights data. The key identifier is the Amazon Resource Name (ARN), AWS KMS key identifier, or the key alias for the CMK. For more information, see Enabling and disabling Performance Insights (p. 415) .	CLI option: <code>--performance-insights-kms-key-id</code> RDS API parameter: <code>PerformanceInsightsKMSKeyId</code>	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines
Performance Insights Retention period The amount of time, in days, to retain Performance Insights data. Valid values are 7 or 731 (2 years). For more information, see Enabling and disabling Performance Insights (p. 415) .	CLI option: <code>--performance-insights-retention-period</code> RDS API parameter: <code>PerformanceInsightsRetentionPeriod</code>	The change occurs immediately. This setting ignores the apply immediately setting.	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
Processor features The number of CPU cores and the number of threads per core for the DB instance class of the DB instance. For more information, see Configuring the processor for a DB instance class (p. 20) .	CLI option: <code>--processor-features</code> and <code>--use-default-processor-features</code> <code>--no-use-default-processor-features</code> RDS API parameter: <code>ProcessorFeatures</code> and <code>UseDefaultProcessorFeatures</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime occurs during this change.	Only Oracle
Provisioned IOPS The new Provisioned IOPS (I/O operations per second) value for the DB instance. The setting is available only if Provisioned IOPS (SSD) is chosen for Storage type . For more information, see Provisioned IOPS SSD storage (p. 42) .	CLI option: <code>--iops</code> RDS API parameter: <code>Iops</code>	If you choose to apply the change immediately, it occurs immediately. If you don't choose to apply the change immediately, it occurs during the next maintenance window.	Downtime doesn't occur during this change.	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
<p>Public access</p> <p>Publicly accessible to give the DB instance a public IP address, meaning that it's accessible outside the VPC. To be publicly accessible, the DB instance also has to be in a public subnet in the VPC.</p> <p>Not publicly accessible to make the DB instance accessible only from inside the VPC.</p> <p>For more information, see Hiding a DB instance in a VPC from the internet (p. 1729).</p> <p>To connect to a DB instance from outside of its Amazon VPC, the DB instance must be publicly accessible, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see Can't connect to Amazon RDS DB instance (p. 1746).</p> <p>If your DB instance is isn't publicly accessible, you can also use an AWS Site-to-Site VPN connection or an AWS Direct Connect connection to access it from a private network. For more information, see Internetwork traffic privacy (p. 1643).</p>	<p>CLI option: <code>--publicly-accessible --no-publicly-accessible</code></p> <p>RDS API parameter: <code>PubliclyAccessible</code></p>	<p>The change occurs immediately. This setting ignores the apply immediately setting.</p>	<p>Downtime doesn't occur during this change.</p>	All DB engines
<p>Security group</p> <p>The VPC security group that you want associated with the DB instance.</p> <p>For more information, see Controlling access with security groups (p. 1699).</p>	<p>CLI option: <code>--vpc-security-group-ids</code></p> <p>RDS API parameter: <code>VpcSecurityGroupIds</code></p>	<p>The change is applied asynchronously, as soon as possible. This setting ignores the apply immediately setting.</p>	<p>Downtime doesn't occur during this change.</p>	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
<p>Storage autoscaling</p> <p>Enable storage autoscaling to enable Amazon RDS to automatically increase storage when needed to avoid having your DB instance run out of storage space.</p> <p>Use Maximum storage threshold to set the upper limit for Amazon RDS to automatically increase storage for your DB instance. The default is 1,000 GiB.</p> <p>For more information, see Managing capacity automatically with Amazon RDS storage autoscaling (p. 317).</p>	<p>CLI option: --max-allocated-storage</p> <p>RDS API parameter: MaxAllocatedStorage</p>	<p>The change occurs immediately. This setting ignores the apply immediately setting.</p>	<p>Downtime doesn't occur during this change.</p>	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
<p>Storage type</p> <p>The storage type that you want to use.</p> <p>After Amazon RDS begins to modify your DB instance to change the storage size or type, you can't submit another request to change the storage size or type for six hours.</p> <p>For more information, see Amazon RDS storage types (p. 40).</p>	<p>CLI option: <code>--storage-type</code></p> <p>RDS API parameter: <code>StorageType</code></p>	<p>If you choose to apply the change immediately, it occurs immediately.</p> <p>If you don't choose to apply the change immediately, it occurs during the next maintenance window.</p>	<p>The following changes all result in a brief downtime while the process starts. After that, you can use your database normally while the change takes place.</p> <ul style="list-style-type: none"> • From General Purpose (SSD) to Magnetic. • From General Purpose (SSD) to Provisioned IOPS (SSD). The downtime only happens if the DB instance is Single-AZ and you are using a custom parameter group. There is no downtime for a Multi-AZ DB instance. • From Magnetic to General Purpose (SSD). • From Magnetic to Provisioned IOPS (SSD). • From Provisioned IOPS (SSD) to Magnetic. • From Provisioned IOPS (SSD) to General Purpose (SSD). The downtime only happens if the DB instance is Single-AZ and you are using a custom parameter group. There is no downtime for a Multi-AZ DB instance. 	All DB engines

Console setting and description	CLI option and RDS API parameter	When the change occurs	Downtime notes	Supported DB engines
<p>Subnet group</p> <p>The subnet group for the DB instance. You can use this setting to move your DB instance to a different VPC. If your DB instance isn't in a VPC, you can use this setting to move your DB instance into a VPC.</p> <p>For more information, see Amazon Virtual Private Cloud VPCs and Amazon RDS (p. 1718).</p>	<p>CLI option: <code>--db-subnet-group-name</code></p> <p>RDS API parameter: <code>DBSubnetGroupName</code></p>	<p>If you choose to apply the change immediately, it occurs immediately.</p> <p>If you don't choose to apply the change immediately, it occurs during the next maintenance window.</p>	Downtime occurs during this change.	All DB engines

Maintaining a DB instance

Periodically, Amazon RDS performs maintenance on Amazon RDS resources. Maintenance most often involves updates to the DB instance's underlying hardware, underlying operating system (OS), or database engine version. Updates to the operating system most often occur for security issues and should be done as soon as possible.

Some maintenance items require that Amazon RDS take your DB instance offline for a short time. Maintenance items that require a resource to be offline include required operating system or database patching. Required patching is automatically scheduled only for patches that are related to security and instance reliability. Such patching occurs infrequently (typically once every few months) and seldom requires more than a fraction of your maintenance window.

Deferred DB instance modifications that you have chosen not to apply immediately are also applied during the maintenance window. For example, you might choose to change the DB instance class or parameter group during the maintenance window. Such modifications that you specify using the **pending reboot** setting don't show up in the **Pending maintenance** list. For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

You can view whether a maintenance update is available for your DB instance by using the RDS console, the AWS CLI, or the Amazon RDS API. If an update is available, it is indicated in the **Maintenance** column for the DB instance on the Amazon RDS console, as shown following.

Current activity	Maintenance	VPC	Multi-AZ
0 Connections	none	vpc-2aed394c	No
0 Connections	next window	vpc-2aed394c	No
0.02 Sessions	none	vpc-2aed394c	No

If no maintenance update is available for a DB instance, the column value is **none** for it.

If a maintenance update is available for a DB instance, the following column values are possible:

- **required** – The maintenance action will be applied to the resource and can't be deferred indefinitely.
- **available** – The maintenance action is available, but it will not be applied to the resource automatically. You can apply it manually.
- **next window** – The maintenance action will be applied to the resource during the next maintenance window.
- **In progress** – The maintenance action is in the process of being applied to the resource.

If an update is available, you can take one of the actions:

- If the maintenance value is **next window**, defer the maintenance items by choosing **Defer upgrade** from **Actions**. You can't defer a maintenance action if it has already started.
- Apply the maintenance items immediately.

- Schedule the maintenance items to start during your next maintenance window.
- Take no action.

Note

Certain OS updates are marked as **required**. If you defer a required update, you get a notice from Amazon RDS indicating when the update will be performed. Other updates are marked as **available**, and these you can defer indefinitely.

To take an action, choose the DB instance to show its details, then choose **Maintenance & backups**. The pending maintenance items appear.

The screenshot shows the AWS RDS console interface. At the top, there are tabs: Connectivity & security, Monitoring, Logs & events, Configuration, Maintenance & backups (which is highlighted in orange), and Tags. Below the tabs, there's a section titled "Maintenance". It shows three status boxes: "Auto minor version upgrade" (Enabled), "Maintenance window" (mon:11:28-mon:11:58 UTC (GMT)), and "Pending maintenance next window". Under "Pending maintenance (1)", there's a table with columns: Description, Type, Status, and Apply date. A single row is listed: "Automatic minor version upgrade to postgres 9.6.11" (db-upgrade, next window, February 25th 2019, 3:28:00 am UTC-8 (local)). There are "Apply now" and "Apply at next maintenance window" buttons above the table, and a "Filter pending maintenance" search bar below it.

The maintenance window determines when pending operations start, but doesn't limit the total run time of these operations. Maintenance operations aren't guaranteed to finish before the maintenance window ends, and can continue beyond the specified end time. For more information, see [The Amazon RDS maintenance window \(p. 268\)](#).

Applying updates for a DB instance

With Amazon RDS, you can choose when to apply maintenance operations. You can decide when Amazon RDS applies updates by using the RDS console, AWS Command Line Interface (AWS CLI), or RDS API.

Console

To manage an update for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that has a required update.
4. For **Actions**, choose one of the following:
 - **Upgrade now**
 - **Upgrade at next window**

Note

If you choose **Upgrade at next window** and later want to delay the update, you can choose **Defer upgrade**. You can't defer a maintenance action if it has already started. To cancel a maintenance action, modify the DB instance and disable **Auto minor version upgrade**.

AWS CLI

To apply a pending update to a DB instance, use the [apply-pending-maintenance-action](#) AWS CLI command.

Example

For Linux, macOS, or Unix:

```
aws rds apply-pending-maintenance-action \
--resource-identifier arn:aws:rds:us-west-2:001234567890:db:mysql-db \
--apply-action system-update \
--opt-in-type immediate
```

For Windows:

```
aws rds apply-pending-maintenance-action ^
--resource-identifier arn:aws:rds:us-west-2:001234567890:db:mysql-db ^
--apply-action system-update ^
--opt-in-type immediate
```

Note

To defer a maintenance action, specify `undo-opt-in` for `--opt-in-type`. You can't specify `undo-opt-in` for `--opt-in-type` if the maintenance action has already started. To cancel a maintenance action, run the [modify-db-instance](#) AWS CLI command and specify `--no-auto-minor-version-upgrade`.

To return a list of resources that have at least one pending update, use the [describe-pending-maintenance-actions](#) AWS CLI command.

Example

For Linux, macOS, or Unix:

```
aws rds describe-pending-maintenance-actions \
--resource-identifier arn:aws:rds:us-west-2:001234567890:db:mysql-db
```

For Windows:

```
aws rds describe-pending-maintenance-actions ^
--resource-identifier arn:aws:rds:us-west-2:001234567890:db:mysql-db
```

You can also return a list of resources for a DB instance by specifying the `--filters` parameter of the `describe-pending-maintenance-actions` AWS CLI command. The format for the `--filters` command is `Name=filter-name,Value=resource-id,...`

The following are the accepted values for the `Name` parameter of a filter:

- `db-instance-id` – Accepts a list of DB instance identifiers or Amazon Resource Names (ARNs). The returned list only includes pending maintenance actions for the DB instances identified by these identifiers or ARNs.
- `db-cluster-id` – Accepts a list of DB cluster identifiers or ARNs for Amazon Aurora. The returned list only includes pending maintenance actions for the DB clusters identified by these identifiers or ARNs.

For example, the following example returns the pending maintenance actions for the `sample-instance1` and `sample-instance2` DB instances.

Example

For Linux, macOS, or Unix:

```
aws rds describe-pending-maintenance-actions \
--filters Name=db-instance-id,Values=sample-instance1,sample-instance2
```

For Windows:

```
aws rds describe-pending-maintenance-actions ^
--filters Name=db-instance-id,Values=sample-instance1,sample-instance2
```

RDS API

To apply an update to a DB instance, call the Amazon RDS API [ApplyPendingMaintenanceAction](#) operation.

To return a list of resources that have at least one pending update, call the Amazon RDS API [DescribePendingMaintenanceActions](#) operation.

Maintenance for Multi-AZ deployments

Running a DB instance as a Multi-AZ deployment can further reduce the impact of a maintenance event, because Amazon RDS applies operating system updates by following these steps:

1. Perform maintenance on the standby.
2. Promote the standby to primary.
3. Perform maintenance on the old primary, which becomes the new standby.

When you modify the database engine for your DB instance in a Multi-AZ deployment, then Amazon RDS upgrades both the primary and secondary DB instances at the same time. In this case, the database engine for the entire Multi-AZ deployment is shut down during the upgrade.

For more information on Multi-AZ deployments, see [High availability \(Multi-AZ\) for Amazon RDS \(p. 53\)](#).

The Amazon RDS maintenance window

Every DB instance has a weekly maintenance window during which any system changes are applied. You can think of the maintenance window as an opportunity to control when modifications and software patching occur, in the event either are requested or required. If a maintenance event is scheduled for a given week, it is initiated during the 30-minute maintenance window you identify. Most maintenance events also complete during the 30-minute maintenance window, although larger maintenance events may take more than 30 minutes to complete.

The 30-minute maintenance window is selected at random from an 8-hour block of time per region. If you don't specify a preferred maintenance window when you create the DB instance, then Amazon RDS assigns a 30-minute maintenance window on a randomly selected day of the week.

RDS will consume some of the resources on your DB instance while maintenance is being applied. You might observe a minimal effect on performance. For a DB instance, on rare occasions, a Multi-AZ failover might be required for a maintenance update to complete.

Following, you can find the time blocks for each region from which default maintenance windows are assigned.

Region Name	Region	Time Block
US East (Ohio)	us-east-2	03:00–11:00 UTC
US East (N. Virginia)	us-east-1	03:00–11:00 UTC
US West (N. California)	us-west-1	06:00–14:00 UTC
US West (Oregon)	us-west-2	06:00–14:00 UTC
Africa (Cape Town)	af-south-1	03:00–11:00 UTC

Adjusting the preferred DB instance maintenance window

The maintenance window should fall at the time of lowest usage and thus might need modification from time to time. Your DB instance will only be unavailable during this time if the system changes, such as a change in DB instance class, are being applied and require an outage, and only for the minimum amount of time required to make the necessary changes.

In the following example, you adjust the preferred maintenance window for a DB instance.

For the purpose of this example, we assume that the DB instance named *mydbinstance* exists and has a preferred maintenance window of "Sun:05:00–Sun:06:00" UTC.

Console

To adjust the preferred maintenance window

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then select the DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB Instance** page appears.
4. In the **Maintenance** section, update the maintenance window.

Note

The maintenance window and the backup window for the DB instance cannot overlap. If you enter a value for the maintenance window that overlaps the backup window, an error message appears.

5. Choose **Continue**.

On the confirmation page, review your changes.

6. To apply the changes to the maintenance window immediately, select **Apply immediately**.
7. Choose **Modify DB Instance** to save your changes.

Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

AWS CLI

To adjust the preferred maintenance window, use the AWS CLI [modify-db-instance](#) command with the following parameters:

- `--db-instance-identifier`
- `--preferred-maintenance-window`

Example

The following code example sets the maintenance window to Tuesdays from 4:00-4:30AM UTC.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--preferred-maintenance-window Tue:04:00-Tue:04:30
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--preferred-maintenance-window Tue:04:00-Tue:04:30
```

RDS API

To adjust the preferred maintenance window, use the Amazon RDS API [ModifyDBInstance](#) operation with the following parameters:

- `DBInstanceIdentifier`
- `PreferredMaintenanceWindow`

Upgrading a DB instance engine version

Amazon RDS provides newer versions of each supported database engine so you can keep your DB instance up-to-date. Newer versions can include bug fixes, security enhancements, and other improvements for the database engine. When Amazon RDS supports a new version of a database engine, you can choose how and when to upgrade your database DB instances.

There are two kinds of upgrades: major version upgrades and minor version upgrades. In general, a *major engine version upgrade* can introduce changes that are not compatible with existing applications. In contrast, a *minor version upgrade* includes only changes that are backward-compatible with existing applications.

The version numbering sequence is specific to each database engine. For example, RDS for MySQL 5.7 and 8.0 are major engine versions and upgrading from any 5.7 version to any 8.0 version is a major version upgrade. RDS for MySQL version 5.7.22 and 5.7.23 are minor versions and upgrading from 5.7.22 to 5.7.23 is a minor version upgrade.

Important

You can't modify a DB instance when it is being upgraded. During an upgrade, the DB instance status is **upgrading**.

For more information about major and minor version upgrades for a specific DB engine, see the following documentation for your DB engine:

- [Upgrading the MariaDB DB engine \(p. 598\)](#)
- [Upgrading the Microsoft SQL Server DB engine \(p. 666\)](#)
- [Upgrading the MySQL DB engine \(p. 853\)](#)
- [Upgrading the Oracle DB engine \(p. 1209\)](#)
- [Upgrading the PostgreSQL DB engine for Amazon RDS \(p. 1533\)](#)

For major version upgrades, you must manually modify the DB engine version through the AWS Management Console, AWS CLI, or RDS API. For minor version upgrades, you can manually modify the engine version, or you can choose to enable auto minor version upgrades.

Topics

- [Manually upgrading the engine version \(p. 271\)](#)
- [Automatically upgrading the minor engine version \(p. 273\)](#)

Manually upgrading the engine version

To manually upgrade the engine version of a DB instance, you can use the AWS Management Console, the AWS CLI, or the RDS API.

Console

To upgrade the engine version of a DB instance by using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to upgrade.
3. Choose **Modify**. The **Modify DB Instance** page appears.

4. For **DB engine version**, choose the new version.
5. Choose **Continue** and check the summary of modifications.
6. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see [Using the Apply Immediately setting \(p. 251\)](#).
7. On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** to save your changes.

Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

AWS CLI

To upgrade the engine version of a DB instance, use the CLI `modify-db-instance` command. Specify the following parameters:

- `--db-instance-identifier` – the name of the DB instance.
- `--engine-version` – the version number of the database engine to upgrade to.

For information about valid engine versions, use the AWS CLI `describe-db-engine-versions` command.

- `--allow-major-version-upgrade` – to upgrade the major version.
- `--no-apply-immediately` – to apply changes during the next maintenance window. To apply changes immediately, use `--apply-immediately`.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --engine-version new_version \
  --allow-major-version-upgrade \
  --no-apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --engine-version new_version ^
  --allow-major-version-upgrade ^
  --no-apply-immediately
```

RDS API

To upgrade the engine version of a DB instance, use the `ModifyDBInstance` action. Specify the following parameters:

- `DBInstanceIdentifier` – the name of the DB instance, for example `mydbinstance`.
- `EngineVersion` – the version number of the database engine to upgrade to. For information about valid engine versions, use the [DescribeDBEngineVersions](#) operation.
- `AllowMajorVersionUpgrade` – whether to allow a major version upgrade. To do so, set the value to `true`.
- `ApplyImmediately` – whether to apply changes immediately or during the next maintenance window. To apply changes immediately, set the value to `true`. To apply changes during the next maintenance window, set the value to `false`.

Automatically upgrading the minor engine version

A *minor engine version* is an update to a DB engine version within a major engine version. For example, a major engine version might be 9.6 with the minor engine versions 9.6.11 and 9.6.12 within it.

If you want Amazon RDS to upgrade the DB engine version of a database automatically, you can enable auto minor version upgrades for the database.

When Amazon RDS designates a minor engine version as the preferred minor engine version, each database that meets both of the following conditions is upgraded to the minor engine version automatically:

- The database is running a minor version of the DB engine that is lower than the preferred minor engine version.
- The database has auto minor version upgrade enabled.

You can control whether auto minor version upgrade is enabled for a DB instance when you perform the following tasks:

- [Creating a DB instance \(p. 141\)](#)
- [Modifying a DB instance \(p. 250\)](#)
- [Creating a read replica \(p. 283\)](#)
- [Restoring a DB instance from a snapshot \(p. 349\)](#)
- [Restoring a DB instance to a specific time \(p. 389\)](#)
- [Importing a DB instance from Amazon S3 \(p. 871\) \(for a MySQL backup on Amazon S3\)](#)

When you perform these tasks, you can control whether auto minor version upgrade is enabled for the DB instance in the following ways:

- Using the console, set the **Auto minor version upgrade** option.
- Using the AWS CLI, set the `--auto-minor-version-upgrade | --no-auto-minor-version-upgrade` option.
- Using the RDS API, set the `AutoMinorVersionUpgrade` parameter.

To determine whether a maintenance update, such as a DB engine version upgrade, is available for your DB instance, you can use the console, AWS CLI, or RDS API. You can also upgrade the DB engine version manually and adjust the maintenance window. For more information, see [Maintaining a DB instance \(p. 264\)](#).

Important

If you plan to migrate an RDS for PostgreSQL DB instance to an Aurora PostgreSQL DB cluster in the near future, we strongly recommend that you disable auto minor version upgrades for the DB instance early in the migration planning phase. Migration to Aurora PostgreSQL might be delayed if the RDS for PostgreSQL version isn't yet supported by Aurora PostgreSQL. For information about Aurora PostgreSQL versions, see [Engine versions for Amazon Aurora PostgreSQL](#).

Renaming a DB instance

You can rename a DB instance by using the AWS Management Console, the AWS CLI `modify-db-instance` command, or the Amazon RDS API `ModifyDBInstance` action. Renaming a DB instance can have far-reaching effects. The following is a list of considerations before you rename a DB instance.

- When you rename a DB instance, the endpoint for the DB instance changes, because the URL includes the name you assigned to the DB instance. You should always redirect traffic from the old URL to the new one.
- When you rename a DB instance, the old DNS name that was used by the DB instance is immediately deleted, although it could remain cached for a few minutes. The new DNS name for the renamed DB instance becomes effective in about 10 minutes. The renamed DB instance is not available until the new name becomes effective.
- You cannot use an existing DB instance name when renaming an instance.
- All read replicas associated with a DB instance remain associated with that instance after it is renamed. For example, suppose you have a DB instance that serves your production database and the instance has several associated read replicas. If you rename the DB instance and then replace it in the production environment with a DB snapshot, the DB instance that you renamed will still have the read replicas associated with it.
- Metrics and events associated with the name of a DB instance are maintained if you reuse a DB instance name. For example, if you promote a read replica and rename it to be the name of the previous primary DB instance, the events and metrics associated with the primary DB instance are associated with the renamed instance.
- DB instance tags remain with the DB instance, regardless of renaming.
- DB snapshots are retained for a renamed DB instance.

Note

A DB instance is an isolated database environment running in the cloud. A DB instance can host multiple databases, or a single Oracle database with multiple schemas. For information about changing a database name, see the documentation for your DB engine.

Renaming to replace an existing DB instance

The most common reasons for renaming a DB instance are that you are promoting a read replica or you are restoring data from a DB snapshot or point-in-time recovery (PITR). By renaming the database, you can replace the DB instance without having to change any application code that references the DB instance. In these cases, you would do the following:

1. Stop all traffic going to the primary DB instance. This can involve redirecting traffic from accessing the databases on the DB instance or some other way you want to use to prevent traffic from accessing your databases on the DB instance.
2. Rename the primary DB instance to a name that indicates it is no longer the primary DB instance as described later in this topic.
3. Create a new primary DB instance by restoring from a DB snapshot or by promoting a read replica, and then give the new instance the name of the previous primary DB instance.
4. Associate any read replicas with the new primary DB instance.

If you delete the old primary DB instance, you are responsible for deleting any unwanted DB snapshots of the old primary DB instance.

For information about promoting a read replica, see [Promoting a read replica to be a standalone DB instance \(p. 285\)](#).

Console

To rename a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to rename.
4. Choose **Modify**.
5. In **Settings**, enter a new name for **DB instance identifier**.
6. Choose **Continue**.
7. To apply the changes immediately, choose **Apply immediately**. Choosing this option can cause an outage in some cases. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).
8. On the confirmation page, review your changes. If they are correct, choose **Modify DB Instance** to save your changes.

Alternatively, choose **Back** to edit your changes, or choose **Cancel** to cancel your changes.

AWS CLI

To rename a DB instance, use the AWS CLI command `modify-db-instance`. Provide the current `--db-instance-identifier` value and `--new-db-instance-identifier` parameter with the new name of the DB instance.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier DBInstanceIdentifier \
  --new-db-instance-identifier NewDBInstanceIdentifier
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier DBInstanceIdentifier ^
  --new-db-instance-identifier NewDBInstanceIdentifier
```

RDS API

To rename a DB instance, call Amazon RDS API operation `ModifyDBInstance` with the following parameters:

- `DBInstanceIdentifier` — existing name for the instance
- `NewDBInstanceIdentifier` — new name for the instance

Rebooting a DB instance

You might need to reboot your DB instance, usually for maintenance reasons. For example, if you make certain modifications, or if you change the DB parameter group associated with the DB instance, you must reboot the instance for the changes to take effect.

Note

If a DB instance isn't using the latest changes to its associated DB parameter group, the AWS Management Console shows the DB parameter group with a status of **pending-reboot**. The **pending-reboot** parameter groups status doesn't result in an automatic reboot during the next maintenance window. To apply the latest parameter changes to that DB instance, manually reboot the DB instance. For more information about parameter groups, see [Working with DB parameter groups \(p. 228\)](#).

Rebooting a DB instance restarts the database engine service. Rebooting a DB instance results in a momentary outage, during which the DB instance status is set to *rebooting*.

If the Amazon RDS instance is configured for Multi-AZ, you can perform the reboot with a failover. An Amazon RDS event is created when the reboot is completed. If your DB instance is a Multi-AZ deployment, you can force a failover from one Availability Zone (AZ) to another when you reboot. When you force a failover of your DB instance, Amazon RDS automatically switches to a standby replica in another Availability Zone, and updates the DNS record for the DB instance to point to the standby DB instance. As a result, you need to clean up and re-establish any existing connections to your DB instance. Rebooting with failover is beneficial when you want to simulate a failure of a DB instance for testing, or restore operations to the original AZ after a failover occurs. For more information, see [High availability \(Multi-AZ\) for Amazon RDS \(p. 53\)](#).

Note

When you force a failover from one Availability Zone to another when you reboot, the Availability Zone change might not be reflected in the AWS Management Console, and in calls to the AWS CLI and RDS API, for several minutes.

You can't reboot your DB instance if it is not in the available state. Your database can be unavailable for several reasons, such as an in-progress backup, a previously requested modification, or a maintenance-window action.

The time required to reboot your DB instance depends on the crash recovery process, database activity at the time of reboot, and the behavior of your specific DB engine. To improve the reboot time, we recommend that you reduce database activity as much as possible during the reboot process. Reducing database activity reduces rollback activity for in-transit transactions.

For a DB instance with read replicas, you can reboot the source DB instance and its read replicas independently. After a reboot completes, replication resumes automatically.

Console

To reboot a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to reboot.
3. For **Actions**, choose **Reboot**.

The **Reboot DB Instance** page appears.

4. (Optional) Choose **Reboot with failover?** to force a failover from one AZ to another.
5. Choose **Reboot** to reboot your DB instance.

Alternatively, choose **Cancel**.

AWS CLI

To reboot a DB instance by using the AWS CLI, call the [reboot-db-instance](#) command.

Example Simple reboot

For Linux, macOS, or Unix:

```
aws rds reboot-db-instance \
--db-instance-identifier mydbinstance
```

For Windows:

```
aws rds reboot-db-instance ^
--db-instance-identifier mydbinstance
```

Example Reboot with failover

To force a failover from one AZ to the other, use the `--force-failover` parameter.

For Linux, macOS, or Unix:

```
aws rds reboot-db-instance \
--db-instance-identifier mydbinstance \
--force-failover
```

For Windows:

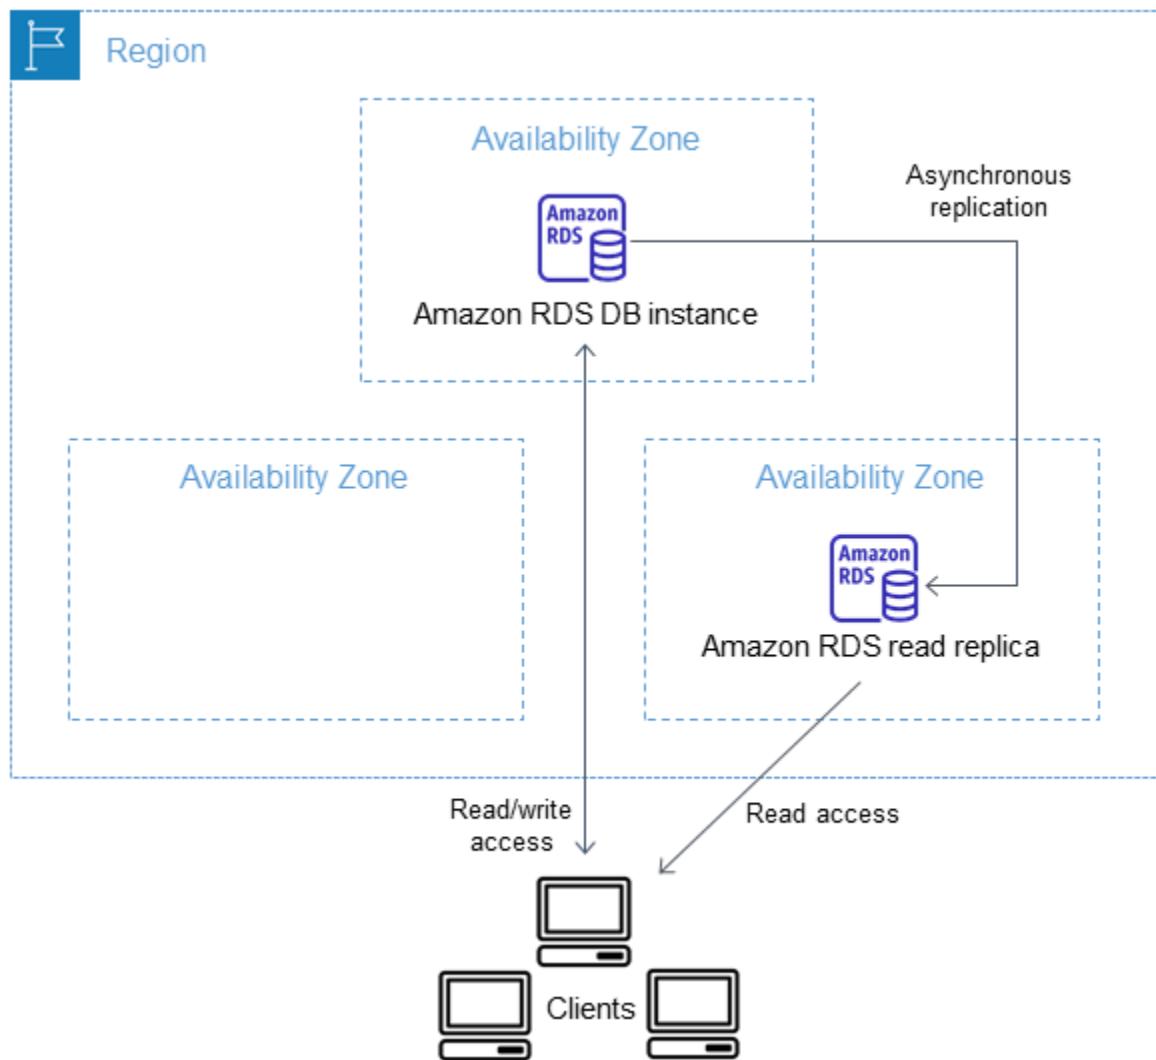

```
aws rds reboot-db-instance ^
--db-instance-identifier mydbinstance ^
--force-failover
```

RDS API

To reboot a DB instance by using the Amazon RDS API, call the [RebootDBInstance](#) operation.

Working with read replicas

Amazon RDS uses the MariaDB, Microsoft SQL Server, MySQL, Oracle, and PostgreSQL DB engines' built-in replication functionality to create a special type of DB instance called a read replica from a source DB instance. The source DB instance becomes the primary DB instance. Updates made to the primary DB instance are asynchronously copied to the read replica. You can reduce the load on your primary DB instance by routing read queries from your applications to the read replica. Using read replicas, you can elastically scale out beyond the capacity constraints of a single DB instance for read-heavy database workloads.

Note

The information following applies to creating Amazon RDS read replicas either in the same AWS Region as the source DB instance, or in a separate AWS Region. The information following doesn't apply to setting up replication with an instance that is running on an Amazon EC2 instance or that is on-premises.

When you create a read replica, you first specify an existing DB instance as the source. Then Amazon RDS takes a snapshot of the source instance and creates a read-only instance from the snapshot. Amazon RDS then uses the asynchronous replication method for the DB engine to update the read replica whenever there is a change to the primary DB instance. The read replica operates as a DB instance that allows only

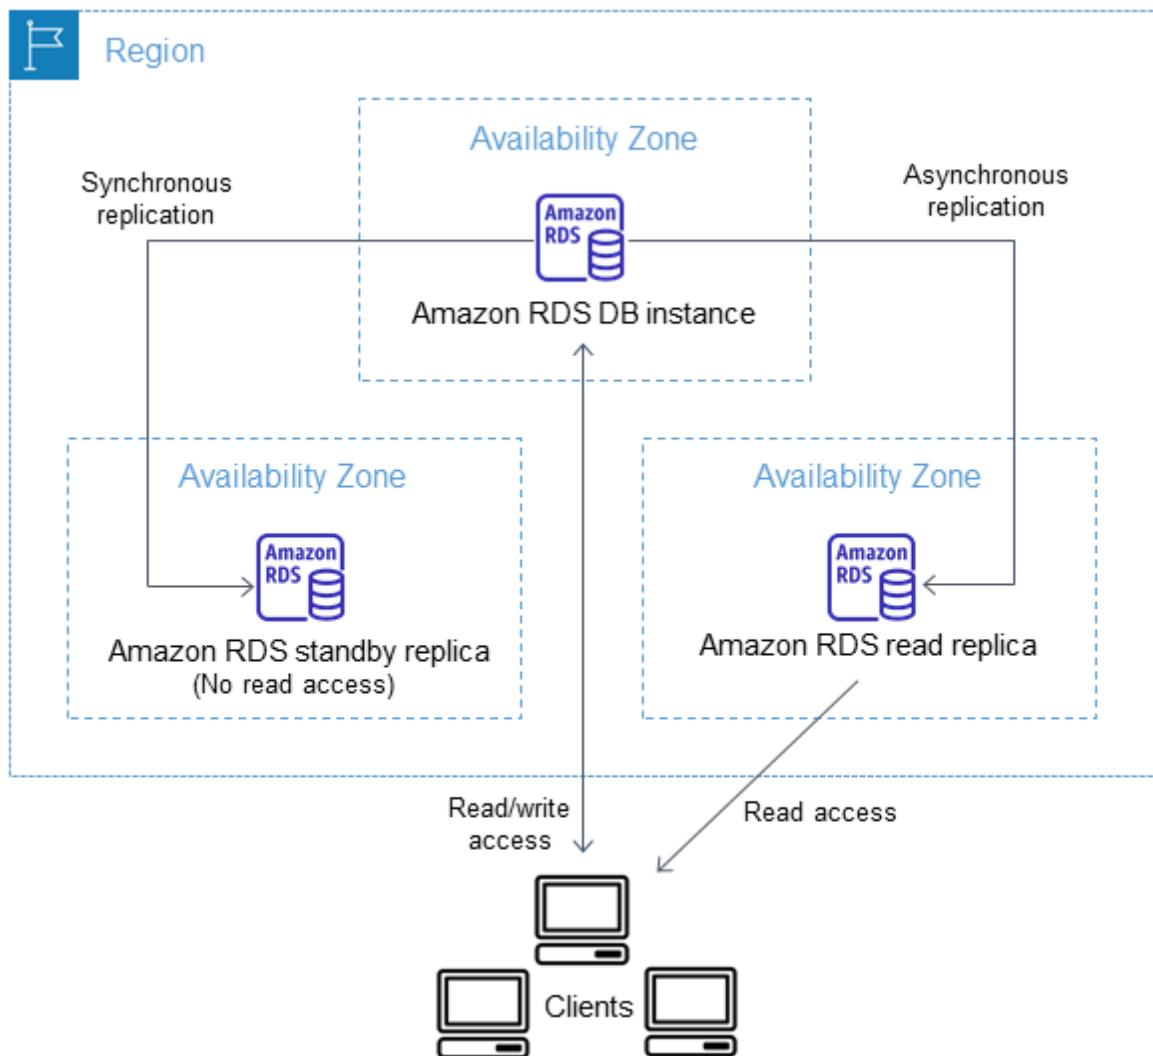

read-only connections. Applications connect to a read replica the same way they do to any DB instance. Amazon RDS replicates all databases in the source DB instance.

Note

The Oracle DB engine supports replica databases in mounted mode. A mounted replica doesn't accept user connections and so can't serve a read-only workload. The primary use for mounted replicas is cross-Region disaster recovery. For more information, see [Working with Oracle replicas for Amazon RDS \(p. 1119\)](#).

In some cases, a read replica resides in a different AWS Region from its primary DB instance. In these cases, Amazon RDS sets up a secure communications channel between the primary DB instance and the read replica. Amazon RDS establishes any AWS security configurations needed to enable the secure channel, such as adding security group entries. For more information about cross-Region read replicas, see [Creating a read replica in a different AWS Region \(p. 290\)](#).

You can configure a read replica for a DB instance that also has a standby replica configured for high availability. Replication with the standby replica is synchronous, and the standby replica can't serve read traffic.

For more information about high availability and standby replicas, see [High availability \(Multi-AZ\) for Amazon RDS \(p. 53\)](#).

Read replicas are supported by the MariaDB, Microsoft SQL Server, MySQL, Oracle, and PostgreSQL DB engines. In this section, you can find general information about using read replicas with all of these engines. For information about using read replicas with a specific engine, see the following sections:

- [Working with MariaDB read replicas \(p. 605\)](#)
- [Working with read replicas for Microsoft SQL Server in Amazon RDS \(p. 696\)](#)
- [Working with MySQL read replicas \(p. 899\)](#)
- [Working with Oracle replicas for Amazon RDS \(p. 1119\)](#)
- [Working with PostgreSQL read replicas in Amazon RDS \(p. 1544\)](#)

Overview of Amazon RDS read replicas

Deploying one or more read replicas for a given source DB instance might make sense in a variety of scenarios, including the following:

- Scaling beyond the compute or I/O capacity of a single DB instance for read-heavy database workloads. You can direct this excess read traffic to one or more read replicas.
- Serving read traffic while the source DB instance is unavailable. In some cases, your source DB instance might not be able to take I/O requests, for example due to I/O suspension for backups or scheduled maintenance. In these cases, you can direct read traffic to your read replicas. For this use case, keep in mind that the data on the read replica might be "stale" because the source DB instance is unavailable.
- Business reporting or data warehousing scenarios where you might want business reporting queries to run against a read replica, rather than your production DB instance.
- Implementing disaster recovery. You can promote a read replica to a standalone instance as a disaster recovery solution if the primary DB instance fails.

By default, a read replica is created with the same storage type as the source DB instance. However, you can create a read replica that has a different storage type from the source DB instance based on the options listed in the following table.

Source DB instance storage type	Source DB instance storage allocation	Read replica storage type options
PIOPS	100 GiB–32 TiB	PIOPS, GP2, Standard
GP2	100 GiB–32 TiB	PIOPS, GP2, Standard
GP2	<100 GiB	GP2, Standard
Standard	100 GiB–6 TiB	PIOPS, GP2, Standard
Standard	<100 GiB	GP2, Standard

Note

When you increase the allocated storage of a read replica, it must be by at least 10 percent. If you try to increase the value by less than 10 percent, you get an error.

Amazon RDS doesn't support circular replication. You can't configure a DB instance to serve as a replication source for an existing DB instance. You can only create a new read replica from an existing DB instance. For example, if `MyDBInstance` replicates to `ReadReplica1`, you can't configure `ReadReplica1` to replicate back to `MyDBInstance`. For MariaDB and MySQL you can create a read replica from an existing read replica. For example, from `ReadReplica1`, you can create a new read

replica, such as [ReadReplica2](#). For Oracle, PostgreSQL, and SQL Server, you can't create a read replica from an existing read replica.

If you no longer need read replicas, you can explicitly delete them using the same mechanisms for deleting a DB instance. If you delete a source DB instance without deleting its read replicas in the same AWS Region, each read replica is promoted to a standalone DB instance. For information about deleting a DB instance, see [Deleting a DB instance \(p. 324\)](#). For information about read replica promotion, see [Promoting a read replica to be a standalone DB instance \(p. 285\)](#). If you have cross-Region read replicas, see [Cross-Region replication considerations \(p. 295\)](#) for considerations related to deleting the source for a cross-Region read replica.

Differences between read replicas for different DB engines

Because Amazon RDS DB engines implement replication differently, there are several significant differences you should know about, as shown in the following table.

Feature or behavior	MySQL and MariaDB	Oracle	PostgreSQL	SQL Server
What is the replication method?	Logical replication.	Physical replication.	Physical replication.	Physical replication.
How are transaction logs purged?	RDS for MySQL and RDS for MariaDB keep any binary logs that haven't been applied.	If a primary DB instance has no cross-Region read replicas, Amazon RDS for Oracle keeps a minimum of two hours of transaction logs on the source DB instance. Logs are purged from the source DB instance after two hours or after the archive log retention hours setting has passed, whichever is longer. Logs are purged from the read replica after the archive log retention hours setting has passed only if they have been successfully applied to the database. In some cases, a primary DB instance might have one or more cross-Region read replicas. If so, Amazon RDS for Oracle keeps the transaction logs on the source	PostgreSQL has the parameter <code>wal_keep_segments</code> that dictates how many write ahead log (WAL) files are kept to provide data to the read replicas. The parameter value specifies the number of logs to keep.	The Virtual Log File (VLF) of the transaction log file on the primary replica can be truncated after it is no longer required for the secondary replicas. The VLF can only be marked as inactive when the log records have been hardened in the replicas. Regardless of how fast the disk subsystems are in the primary replica, the transaction log will keep the VLFs until the slowest

Feature or behavior	MySQL and MariaDB	Oracle	PostgreSQL	SQL Server
		<p>DB instance until they have been transmitted and applied to all cross-Region read replicas.</p> <p>For information about setting archive log retention hours, see Retaining archived redo logs (p. 1067).</p>		replica has hardened it.
Can a replica be made writable?	Yes. You can enable the MySQL or MariaDB read replica to be writable.	No. An Oracle read replica is a physical copy, and Oracle doesn't allow for writes in a read replica. You can promote the read replica to make it writable. The promoted read replica has the replicated data to the point when the request was made to promote it.	No. A PostgreSQL read replica is a physical copy, and PostgreSQL doesn't allow for a read replica to be made writable.	No. A SQL Server read replica is a physical copy and also doesn't allow for writes. You can promote the read replica to make it writable. The promoted read replica has the replicated data up to the point when the request was made to promote it.
Can backups be performed on the replica?	Yes. You can enable automatic backups on a MySQL or MariaDB read replica.	No. You can't create manual snapshots of Amazon RDS for Oracle read replicas or enable automatic backups for them.	Yes, you can create a manual snapshot of a PostgreSQL read replica, but you can't enable automatic backups.	No. You can't create manual snapshots of Amazon RDS for SQL Server read replicas or enable automatic backups for them.

Feature or behavior	MySQL and MariaDB	Oracle	PostgreSQL	SQL Server
Can you use parallel replication?	Yes. MySQL version 5.6 and later and all supported MariaDB versions allow for parallel replication threads.	Yes. Redo log data is always transmitted in parallel from the primary database to all of its read replicas.	No. PostgreSQL has a single process handling replication.	Yes. Redo log data is always transmitted in parallel from the primary database to all of its read replicas.
Can you maintain a replica in a mounted rather than a read-only state?	No.	Yes. The primary use for mounted replicas is cross-Region disaster recovery. An Active Data Guard license isn't required for mounted replicas. For more information, see Working with Oracle replicas for Amazon RDS (p. 1119) .	No.	No.

Creating a read replica

You can create a read replica from an existing DB instance using the AWS Management Console, AWS CLI, or RDS API. You create a read replica by specifying `SourceDBInstanceIdentifier`, which is the DB instance identifier of the source DB instance that you want to replicate from.

When you create a read replica, Amazon RDS takes a DB snapshot of your source DB instance and begins replication. As a result, you experience a brief I/O suspension on your source DB instance while the DB snapshot occurs.

Note

The I/O suspension typically lasts about one minute. You can avoid the I/O suspension if the source DB instance is a Multi-AZ deployment, because in that case the snapshot is taken from the secondary DB instance.

An active, long-running transaction can slow the process of creating the read replica. We recommend that you wait for long-running transactions to complete before creating a read replica. If you create multiple read replicas in parallel from the same source DB instance, Amazon RDS takes only one snapshot at the start of the first create action.

When creating a read replica, there are a few things to consider. First, you must enable automatic backups on the source DB instance by setting the backup retention period to a value other than 0. This requirement also applies to a read replica that is the source DB instance for another read replica. For MySQL DB instances, automatic backups are supported only for read replicas running MySQL 5.6 and later, but not for MySQL versions 5.5. To enable automatic backups on an RDS for MySQL version 5.6 and later read replica, first create the read replica, then modify the read replica to enable automatic backups.

Note

Within an AWS Region, we strongly recommend that you create all read replicas in the same virtual private cloud (VPC) based on Amazon VPC as the source DB instance. If you create a read replica in a different VPC from the source DB instance, classless inter-domain routing (CIDR)

ranges can overlap between the replica and the RDS system. CIDR overlap makes the replica unstable, which can negatively impact applications connecting to it. If you receive an error when creating the read replica, choose a different destination DB subnet group. For more information, see [Working with a DB instance in a VPC \(p. 1727\)](#).

You can't create a read replica in a different AWS account from the source DB instance.

Console

To create a read replica from a source DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to use as the source for a read replica.
4. For **Actions**, choose **Create read replica**.
5. For **DB instance identifier**, enter a name for the read replica.
6. Choose your instance specifications. We recommend that you use the same DB instance class and storage type as the source DB instance for the read replica.
7. For **Multi-AZ deployment**, choose **Yes** to create a standby of your replica in another Availability Zone for failover support for the replica.

Note

Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

8. To create an encrypted read replica:
 - a. Choose **Enable encryption**.
 - b. For **Master key**, choose the AWS Key Management Service (AWS KMS) key identifier of the customer master key (CMK).

Note

The source DB instance must be encrypted. To learn more about encrypting the source DB instance, see [Encrypting Amazon RDS resources \(p. 1630\)](#).

9. Choose other options, such as storage autoscaling.
10. Choose **Create read replica**.

AWS CLI

To create a read replica from a source DB instance, use the AWS CLI command `create-db-instance-read-replica`. This example also enables storage autoscaling.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \
--db-instance-identifier myreadreplica \
--source-db-instance-identifier mydbinstance \
--max-allocated-storage 1000
```

For Windows:

```
aws rds create-db-instance-read-replica ^
```

```
--db-instance-identifier myreadreplica ^
--source-db-instance-identifier mydbinstance ^
--max-allocated-storage 1000
```

RDS API

To create a read replica from a source MySQL, MariaDB, Oracle, PostgreSQL, or SQL Server DB instance, call the Amazon RDS API [CreateDBInstanceReadReplica](#) operation with the following required parameters:

- `DBInstanceIdentifier`
- `SourceDBInstanceIdentifier`

Promoting a read replica to be a standalone DB instance

You can promote a read replica into a standalone DB instance. When you promote a read replica, the DB instance is rebooted before it becomes available.

There are several reasons you might want to promote a read replica to a standalone DB instance:

- **Performing DDL operations (MySQL and MariaDB only)** – DDL operations, such as creating or rebuilding indexes, can take time and impose a significant performance penalty on your DB instance. You can perform these operations on a MySQL or MariaDB read replica once the read replica is in sync with its primary DB instance. Then you can promote the read replica and direct your applications to use the promoted instance.
- **Sharding** – Sharding embodies the "share-nothing" architecture and essentially involves breaking a large database into several smaller databases. One common way to split a database is splitting tables that are not joined in the same query onto different hosts. Another method is duplicating a table across multiple hosts and then using a hashing algorithm to determine which host receives a given update. You can create read replicas corresponding to each of your shards (smaller databases) and

promote them when you decide to convert them into standalone shards. You can then carve out the key space (if you are splitting rows) or distribution of tables for each of the shards depending on your requirements.

- **Implementing failure recovery** – You can use read replica promotion as a data recovery scheme if the primary DB instance fails. This approach complements synchronous replication, automatic failure detection, and failover.

If you are aware of the ramifications and limitations of asynchronous replication and you still want to use read replica promotion for data recovery, you can. To do this, first create a read replica and then monitor the primary DB instance for failures. In the event of a failure, do the following:

1. Promote the read replica.
2. Direct database traffic to the promoted DB instance.
3. Create a replacement read replica with the promoted DB instance as its source.

When you promote a read replica, the new DB instance that is created retains the option group and the parameter group of the former read replica. The promotion process can take several minutes or longer to complete, depending on the size of the read replica. After you promote the read replica to a new DB instance, it's just like any other DB instance. For example, you can create read replicas from the new DB instance and perform point-in-time restore operations. Because the promoted DB instance is no longer a read replica, you can't use it as a replication target. If a source DB instance has several read replicas, promoting one of the read replicas to a DB instance has no effect on the other replicas.

Backup duration is a function of the number of changes to the database since the previous backup. If you plan to promote a read replica to a standalone instance, we recommend that you enable backups and complete at least one backup prior to promotion. In addition, you can't promote a read replica to a standalone instance when it has the `Backing-up` status. If you have enabled backups on your read replica, configure the automated backup window so that daily backups don't interfere with read replica promotion.

The following steps show the general process for promoting a read replica to a DB instance:

1. Stop any transactions from being written to the primary DB instance, and then wait for all updates to be made to the read replica. Database updates occur on the read replica after they have occurred on the primary DB instance, and this replication lag can vary significantly. Use the [Replica Lag](#) metric to determine when all updates have been made to the read replica.
2. For MySQL and MariaDB only: If you need to make changes to the MySQL or MariaDB read replica, you must set the `read_only` parameter to `0` in the DB parameter group for the read replica. You can then perform all needed DDL operations, such as creating indexes, on the read replica. Actions taken on the read replica don't affect the performance of the primary DB instance.
3. Promote the read replica by using the **Promote** option on the Amazon RDS console, the AWS CLI command [promote-read-replica](#), or the [PromoteReadReplica](#) Amazon RDS API operation.

Note

The promotion process takes a few minutes to complete. When you promote a read replica, replication is stopped and the read replica is rebooted. When the reboot is complete, the read replica is available as a new DB instance.

4. (Optional) Modify the new DB instance to be a Multi-AZ deployment. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#) and [High availability \(Multi-AZ\) for Amazon RDS \(p. 53\)](#).

Console

To promote a read replica to a standalone DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the Amazon RDS console, choose **Databases**.
The **Databases** pane appears. Each read replica shows **Replica** in the **Role** column.
3. Choose the read replica that you want to promote.
4. For **Actions**, choose **Promote**.
5. On the **Promote Read Replica** page, enter the backup retention period and the backup window for the newly promoted DB instance.
6. When the settings are as you want them, choose **Continue**.
7. On the acknowledgment page, choose **Promote Read Replica**.

AWS CLI

To promote a read replica to a standalone DB instance, use the AWS CLI [promote-read-replica](#) command.

Example

For Linux, macOS, or Unix:

```
aws rds promote-read-replica \
--db-instance-identifier myreadreplica
```

For Windows:

```
aws rds promote-read-replica ^
--db-instance-identifier myreadreplica
```

RDS API

To promote a read replica to a standalone DB instance, call the Amazon RDS API [PromoteReadReplica](#) operation with the required parameter **DBInstanceIdentifier**.

Monitoring read replication

You can monitor the status of a read replica in several ways. The Amazon RDS console shows the status of a read replica in the **Availability and durability** section of the read replica details. To view the details for a read replica, choose the name of the read replica in the list of instances in the Amazon RDS console.

Availability and durability

DB instance status

available

Replication state

replicating

Replication error

-

You can also see the status of a read replica using the AWS CLI `describe-db-instances` command or the Amazon RDS API `DescribeDBInstances` operation.

The status of a read replica can be one of the following:

- **replicating** – The read replica is replicating successfully.
- **replication degraded (SQL Server only)** – Replicas are receiving data from the primary instance, but one or more databases might be not getting updates. This can occur, for example, when a replica is in the process of setting up newly created databases.

The status doesn't transition from `replication degraded` to `error`, unless an error occurs during the degraded state.

- **error** – An error has occurred with the replication. Check the **Replication Error** field in the Amazon RDS console or the event log to determine the exact error. For more information about troubleshooting a replication error, see [Troubleshooting a MySQL read replica problem \(p. 908\)](#).
- **terminated (MariaDB, MySQL, or PostgreSQL only)** – Replication is terminated. This occurs if replication is stopped for more than 30 consecutive days, either manually or due to a replication error. In this case, Amazon RDS terminates replication between the primary DB instance and all read replicas. Amazon RDS does this to prevent increased storage requirements on the source DB instance and long failover times.

Broken replication can affect storage because the logs can grow in size and number due to the high volume of errors messages being written to the log. Broken replication can also affect failure recovery due to the time Amazon RDS requires to maintain and process the large number of logs during recovery.

- **stopped (MariaDB or MySQL only)** – Replication has stopped because of a customer-initiated request.
- **replication stop point set (MySQL only)** – A customer-initiated stop point was set using the [mysql.rds_start_replication_until \(p. 965\)](#) stored procedure and the replication is in progress.
- **replication stop point reached (MySQL only)** – A customer-initiated stop point was set using the [mysql.rds_start_replication_until \(p. 965\)](#) stored procedure and replication is stopped because the stop point was reached.

Monitoring replication lag

You can monitor replication lag in Amazon CloudWatch by viewing the `Amazon RDS ReplicaLag` metric.

For MySQL and MariaDB, the `ReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the `SHOW SLAVE STATUS` command. Common causes for replication lag for MySQL and MariaDB are the following:

- A network outage.
- Writing to tables with indexes on a read replica. If the `read_only` parameter is not set to 0 on the read replica, it can break replication.
- Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB storage engine on MySQL and the XtraDB storage engine on MariaDB.

When the `ReplicaLag` metric reaches 0, the replica has caught up to the primary DB instance. If the `ReplicaLag` metric returns -1, then replication is currently not active. `ReplicaLag = -1` is equivalent to `Seconds_Behind_Master = NULL`.

For Oracle, the `ReplicaLag` metric is the sum of the `Apply_Lag` value and the difference between the current time and the apply lag's `DATUM_TIME` value. The `DATUM_TIME` value is the last time the read replica received data from its source DB instance. For more information, see [V\\$DATAGUARD_STATS](#) in the Oracle documentation.

For SQL Server, the `ReplicaLag` metric is the maximum lag of databases that have fallen behind, in seconds. For example, if you have two databases that lag 5 seconds and 10 seconds, respectively, then `ReplicaLag` is 10 seconds. The `ReplicaLag` metric returns the value of the following query.

```
select ag.name name, MAX(hdrs.secondary_lag_seconds) max_lag from
sys.dm_hadr_database_replica_state
```

For more information, see [secondary_lag_seconds](#) in the Microsoft documentation.

`ReplicaLag` returns -1 if RDS can't determine the lag, such as during replica setup, or when the read replica is in the `error` state.

Note

New databases aren't included in the lag calculation until they are accessible on the read replica.

For PostgreSQL, the `ReplicaLag` metric returns the value of the following query.

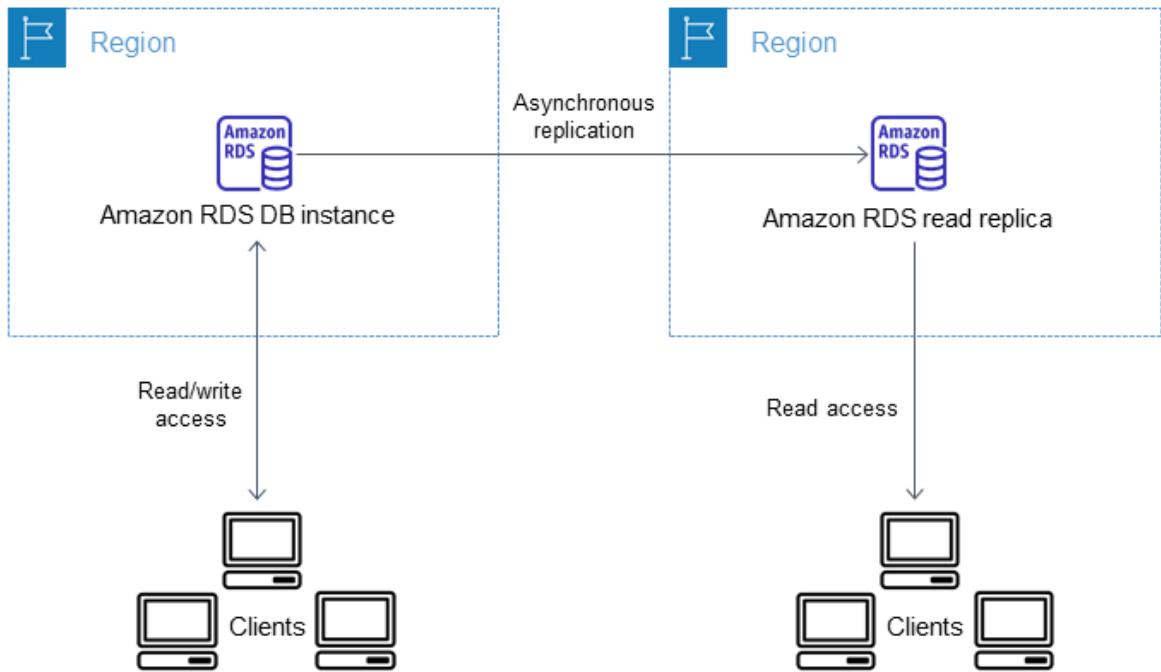

```
SELECT extract(epoch from now() - pg_last_xact_replay_timestamp()) AS reader_lag
```

PostgreSQL versions 9.5.2 and later use physical replication slots to manage write ahead log (WAL) retention on the source instance. For each cross-Region read replica instance, Amazon RDS creates a physical replication slot and associates it with the instance. Two Amazon CloudWatch metrics, `Oldest Replication Slot Lag` and `Transaction Logs Disk Usage`, show how far behind the most lagging replica is in terms of WAL data received and how much storage is being used for WAL data. The `Transaction Logs Disk Usage` value can substantially increase when a cross-Region read replica is lagging significantly.

For more information about monitoring a DB instance with CloudWatch, see [Monitoring Amazon RDS metrics with Amazon CloudWatch \(p. 540\)](#).

Creating a read replica in a different AWS Region

With Amazon RDS, you can create a MariaDB, MySQL, Oracle, or PostgreSQL read replica in a different AWS Region from the source DB instance. Creating a cross-Region read replica isn't supported for SQL Server on Amazon RDS.

You create a read replica in a different AWS Region to do the following:

- Improve your disaster recovery capabilities.
- Scale read operations into an AWS Region closer to your users.
- Make it easier to migrate from a data center in one AWS Region to a data center in another AWS Region.

Creating a read replica in a different AWS Region from the source instance is similar to creating a replica in the same AWS Region. You can use the AWS Management Console, run the [create-db-instance-read-replica](#) command, or call the [CreateDBInstanceReadReplica](#) API operation.

Note

To create an encrypted read replica in a different AWS Region from the source DB instance, the source DB instance must be encrypted.

Creating a cross-Region read replica

The following procedures show how to create a read replica from a source MariaDB, MySQL, Oracle, or PostgreSQL DB instance in a different AWS Region.

Console

You can create a read replica across AWS Regions using the AWS Management Console.

To create a read replica across AWS Regions with the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the MariaDB, MySQL, Oracle, or PostgreSQL DB instance that you want to use as the source for a read replica.
4. For **Actions**, choose **Create read replica**.

5. For **DB instance identifier**, enter a name for the read replica.
6. Choose the **Destination Region**.
7. Choose the instance specifications you want to use. We recommend that you use the same DB instance class and storage type for the read replica.
8. To create an encrypted read replica in another AWS Region:
 - a. Choose **Enable encryption**.
 - b. For **Master key**, choose the AWS Key Management Service (AWS KMS) key identifier of the customer master key (CMK) of the destination AWS Region.

Note

To create an encrypted read replica, the source DB instance must be encrypted. To learn more about encrypting the source DB instance, see [Encrypting Amazon RDS resources \(p. 1630\)](#).

9. Choose other options, such as storage autoscaling.
10. Choose **Create read replica**.

AWS CLI

To create a read replica from a source MySQL, MariaDB, Oracle, or PostgreSQL DB instance in a different AWS Region, you can use the `create-db-instance-read-replica` command. In this case, you use `create-db-instance-read-replica` from the AWS Region where you want the read replica (destination Region) and specify the Amazon Resource Name (ARN) for the source DB instance. An ARN uniquely identifies a resource created in Amazon Web Services.

For example, if your source DB instance is in the US East (N. Virginia) Region, the ARN looks similar to this example:

```
arn:aws:rds:us-east-1:123456789012:db:mydbinstance
```

For information about ARNs, see [Working with Amazon Resource Names \(ARNs\) in Amazon RDS \(p. 309\)](#).

To create a read replica in a different AWS Region from the source DB instance, you can use the AWS CLI `create-db-instance-read-replica` command from the destination AWS Region. The following parameters are required for creating a read replica in another AWS Region:

- `--region` – The destination AWS Region where the read replica is created.
- `--source-db-instance-identifier` – The DB instance identifier for the source DB instance. This identifier must be in the ARN format for the source AWS Region. The AWS Region specified in `source-db-instance-identifier` must match the AWS Region specified in `--region`.
- `--db-instance-identifier` – The identifier for the read replica in the destination AWS Region.

Example of a cross-Region read replica

The following code creates a read replica in the US West (Oregon) Region from a source DB instance in the US East (N. Virginia) Region.

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \
    --db-instance-identifier myreadreplica \
    --region us-west-2 \
```

```
--source-db-instance-identifier arn:aws:rds:us-east-1:123456789012:db:mydbinstance
```

For Windows:

```
aws rds create-db-instance-read-replica ^
--db-instance-identifier myreadreplica ^
--region us-west-2 ^
--source-db-instance-identifier arn:aws:rds:us-east-1:123456789012:db:mydbinstance
```

The following parameters are also required for creating an encrypted read replica in another AWS Region:

- **--source-region** – The AWS Region of the source DB instance.
If **--source-region** isn't specified, you must specify a **--pre-signed-url** value. A presigned URL is a URL that contains a Signature Version 4 signed request for the `CreateDBInstanceReadReplica` operation that is called in the source AWS Region. For more information about presigned URLs, see [CreateDBInstanceReadReplica](#).
- **--kms-key-id** – The AWS KMS key identifier for the customer master key (CMK) to use to encrypt the read replica in the destination AWS Region.

Example of an encrypted cross-Region read replica

The following code creates an encrypted read replica in the US West (Oregon) Region from a source DB instance in the US East (N. Virginia) Region.

For Linux, macOS, or Unix:

```
aws rds create-db-instance-read-replica \
--db-instance-identifier myreadreplica \
--region us-west-2 \
--source-db-instance-identifier arn:aws:rds:us-east-1:123456789012:db:mydbinstance \
--source-region us-east-1 \
--kms-key-id my-us-west-2-key
```

For Windows:

```
aws rds create-db-instance-read-replica ^
--db-instance-identifier myreadreplica ^
--region us-west-2 ^
--source-db-instance-identifier arn:aws:rds:us-east-1:123456789012:db:mydbinstance ^
--source-region us-east-1 ^
--kms-key-id my-us-west-2-key
```

RDS API

To create a read replica from a source MySQL, MariaDB, Oracle, or PostgreSQL DB instance in a different AWS Region, you can call the Amazon RDS API function [CreateDBInstanceReadReplica](#). In this case, you call `CreateDBInstanceReadReplica` from the AWS Region where you want the read replica (destination Region) and specify the Amazon Resource Name (ARN) for the source DB instance. An ARN uniquely identifies a resource created in Amazon Web Services.

To create an encrypted read replica in a different AWS Region from the source DB instance, you can use the Amazon RDS API [CreateDBInstanceReadReplica](#) operation from the destination AWS Region. To create an encrypted read replica in another AWS Region, you must specify a value for `PreSignedURL`.

`PreSignedURL` should contain a request for the [CreateDBInstanceReadReplica](#) operation to call in the source AWS Region where the read replica is created in. To learn more about `PreSignedUrl`, see [CreateDBInstanceReadReplica](#).

For example, if your source DB instance is in the US East (N. Virginia) Region, the ARN looks similar to the following.

```
arn:aws:rds:us-east-1:123456789012:db:mydbinstance
```

For information about ARNs, see [Working with Amazon Resource Names \(ARNs\) in Amazon RDS \(p. 309\)](#).

Example

```
https://us-west-2.rds.amazonaws.com/

```

How Amazon RDS does cross-Region replication

Amazon RDS uses the following process to create a cross-Region read replica. Depending on the AWS Regions involved and the amount of data in the databases, this process can take hours to complete. You can use this information to determine how far the process has proceeded when you create a cross-Region read replica:

1. Amazon RDS begins configuring the source DB instance as a replication source and sets the status to *modifying*.
2. Amazon RDS begins setting up the specified read replica in the destination AWS Region and sets the status to *creating*.
3. Amazon RDS creates an automated DB snapshot of the source DB instance in the source AWS Region. The format of the DB snapshot name is `rds:<InstanceID>-<timestamp>`, where `<InstanceID>` is the identifier of the source instance, and `<timestamp>` is the date and time the copy started.

For example, `rds:mysourceinstance-2013-11-14-09-24` was created from the instance `mysourceinstance` at 2013-11-14-09-24. During the creation of an automated DB snapshot, the source DB instance status remains *modifying*, the read replica status remains *creating*, and the DB snapshot status is *creating*. The progress column of the DB snapshot page in the console reports how far the DB snapshot creation has progressed. When the DB snapshot is complete, the status of both the DB snapshot and source DB instance are set to *available*.

4. Amazon RDS begins a cross-Region snapshot copy for the initial data transfer. The snapshot copy is listed as an automated snapshot in the destination AWS Region with a status of *creating*. It has the same name as the source DB snapshot. The progress column of the DB snapshot display indicates how far the copy has progressed. When the copy is complete, the status of the DB snapshot copy is set to *available*.
5. Amazon RDS then uses the copied DB snapshot for the initial data load on the read replica. During this phase, the read replica is in the list of DB instances in the destination, with a status of *creating*. When the load is complete, the read replica status is set to *available*, and the DB snapshot copy is deleted.
6. When the read replica reaches the available status, Amazon RDS starts by replicating the changes made to the source instance since the start of the create read replica operation. During this phase, the replication lag time for the read replica is greater than 0.

For information about replication lag time, see [Monitoring read replication \(p. 288\)](#).

Cross-Region replication considerations

All of the considerations for performing replication within an AWS Region apply to cross-Region replication. The following extra considerations apply when replicating between AWS Regions:

- You can only replicate between AWS Regions when using the following Amazon RDS DB instances:
 - MariaDB (all versions).
 - MySQL version 5.6 and later.
 - Oracle Enterprise Edition (EE) engine version 12.1.0.2.v10 and higher 12.1 versions, and all versions of 12.2, 18c, and 19c.

An Active Data Guard license is required. For information about limitations for Oracle cross-Region read replicas, see [Replica requirements for Oracle \(p. 1119\)](#).

- PostgreSQL (all versions).
- A source DB instance can have cross-Region read replicas in multiple AWS Regions.
- You can only create a cross-Region Amazon RDS read replica from a source Amazon RDS DB instance that is not a read replica of another Amazon RDS DB instance.
- You can replicate between the AWS GovCloud (US-East) and AWS GovCloud (US-West) Regions, but not into or out of AWS GovCloud (US).
- You can expect to see a higher level of lag time for any read replica that is in a different AWS Region than the source instance. This lag time comes from the longer network channels between regional data centers.
- For cross-Region read replicas, any of the create read replica commands that specify the `--db-subnet-group-name` parameter must specify a DB subnet group from the same VPC.
- You can create a cross-Region read replica:
 - In a VPC from a source DB instance that is in a VPC in another AWS Region
 - In a VPC from a source DB instance that isn't in a VPC
 - That isn't in a VPC from a source DB instance that is in a VPC
- Due to the limit on the number of access control list (ACL) entries for a VPC, we can't guarantee more than five cross-Region read replica instances.
- The read replica uses the default DB parameter group for the specified DB engine.
- The read replica uses the default security group.

- For MariaDB, MySQL, and Oracle DB instances, when the source for a cross-Region read replica is deleted, the read replica is promoted.
- For PostgreSQL DB instances, when the source for a cross-Region read replica is deleted, the replication status of the read replica is set to terminated. The read replica isn't promoted.

Requesting a cross-Region read replica

To communicate with the source Region to request the creation of a cross-Region read replica, the requester (IAM role or IAM user) must have access to the source DB instance and the source Region.

Certain conditions in the requester's IAM policy can cause the request to fail. The following examples assume that the source DB instance is in US East (Ohio) and the read replica is created in US East (N. Virginia). These examples show conditions in the requester's IAM policy that cause the request to fail:

- The requester's policy has a condition for `aws:RequestedRegion`.

```

...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "*",
"Condition": {
    "StringEquals": {
        "aws:RequestedRegion": "us-east-1"
    }
}

```

The request fails because the policy doesn't allow access to the source Region. For a successful request, specify both the source and destination Regions.

```

...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "*",
"Condition": {
    "StringEquals": {
        "aws:RequestedRegion": [
            "us-east-1",
            "us-east-2"
        ]
    }
}

```

- The requester's policy doesn't allow access to the source DB instance.

```

...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "arn:aws:rds:us-east-1:123456789012:db:myreadreplica"
...
```

For a successful request, specify both the source instance and the replica.

```

...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": [
    "arn:aws:rds:us-east-1:123456789012:db:myreadreplica",
    "arn:aws:rds:us-east-2:123456789012:db:mydbinstance"
]

```

...

- The requester's policy denies aws:ViaAWSservice.

```

...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "*",
"Condition": {
    "Bool": {"aws:ViaAWSservice": "false"}
}

```

Communication with the source Region is made by RDS on the requester's behalf. For a successful request, don't deny calls made by AWS services.

- The requester's policy has a condition for aws:SourceVpc or aws:SourceVpce.

These requests might fail because when RDS makes the call to the remote Region, it isn't from the specified VPC or VPC endpoint.

If you need to use one of the previous conditions that would cause a request to fail, you can include a second statement with aws:CalledVia in your policy to make the request succeed. For example, you can use aws:CalledVia with aws:SourceVpce as shown here:

```

...
"Effect": "Allow",
"Action": "rds:CreateDBInstanceReadReplica",
"Resource": "*",
"Condition": {
    "Condition" : {
        "ForAnyValue:StringEquals" : {
            "aws:SourceVpce": "vpce-1a2b3c4d"
        }
    }
},
{
    "Effect": "Allow",
    "Action": [
        "rds:CreateDBInstanceReadReplica"
    ],
    "Resource": "*",
    "Condition": {
        "ForAnyValue:StringEquals": {
            "aws:CalledVia": [
                "rds.amazonaws.com"
            ]
        }
    }
}

```

For more information, see [Policies and permissions in IAM](#) in the *IAM User Guide*.

Authorizing the read replica

After a cross-Region DB read replica creation request returns success, RDS starts the replica creation in the background. An authorization for RDS to access the source DB instance is created. This authorization links the source DB instance to the read replica, and allows RDS to copy only to the specified read replica.

The authorization is verified by RDS using the rds:CrossRegionCommunication permission in the service-linked IAM role. If the replica is authorized, RDS communicates with the source Region and completes the replica creation.

RDS doesn't have access to DB instances that weren't authorized previously by a `CreateDBInstanceReadReplica` request. The authorization is revoked when read replica creation completes.

RDS uses the service-linked role to verify the authorization in the source Region. If you delete the service-linked role during the replication creation process, the creation fails.

For more information, see [Using service-linked roles](#) in the *IAM User Guide*.

Using AWS Security Token Service credentials

Session tokens from the global AWS Security Token Service (AWS STS) endpoint are valid only in AWS Regions that are enabled by default (commercial Regions). If you use credentials from the `assumeRole` API operation in AWS STS, use the regional endpoint if the source Region is an opt-in Region. Otherwise, the request fails. This happens because your credentials must be valid in both Regions, which is true for opt-in Regions only when the regional AWS STS endpoint is used.

To use the global endpoint, make sure that it's enabled for both Regions in the operations. Set the global endpoint to `Valid in all AWS Regions` in the AWS STS account settings.

The same rule applies to credentials in the presigned URL parameter.

For more information, see [Managing AWS STS in an AWS Region](#) in the *IAM User Guide*.

Cross-Region replication costs

The data transferred for cross-Region replication incurs Amazon RDS data transfer charges. These cross-Region replication actions generate charges for the data transferred out of the source AWS Region:

- When you create a read replica, Amazon RDS takes a snapshot of the source instance and transfers the snapshot to the read replica AWS Region.
- For each data modification made in the source databases, Amazon RDS transfers data from the source AWS Region to the read replica AWS Region.

For more information about data transfer pricing, see [Amazon RDS pricing](#).

For MySQL and MariaDB instances, you can reduce your data transfer costs by reducing the number of cross-Region read replicas that you create. For example, suppose that you have a source DB instance in one AWS Region and want to have three read replicas in another AWS Region. In this case, you create only one of the read replicas from the source DB instance. You create the other two replicas from the first read replica instead of the source DB instance.

For example, if you have `source-instance-1` in one AWS Region, you can do the following:

- Create `read-replica-1` in the new AWS Region, specifying `source-instance-1` as the source.
- Create `read-replica-2` from `read-replica-1`.
- Create `read-replica-3` from `read-replica-1`.

In this example, you are only charged for the data transferred from `source-instance-1` to `read-replica-1`. You aren't charged for the data transferred from `read-replica-1` to the other two replicas because they are all in the same AWS Region. If you create all three replicas directly from `source-instance-1`, you are charged for the data transfers to all three replicas.

Tagging Amazon RDS resources

You can use Amazon RDS tags to add metadata to your Amazon RDS resources. You can use the tags to add your own notations about database instances, snapshots, Aurora clusters, and so on. Doing so can help you to document your Amazon RDS resources. You can also use the tags with automated maintenance procedures.

In particular, you can use these tags with IAM policies to manage access to Amazon RDS resources and to control what actions can be applied to the Amazon RDS resources. You can also use these tags to track costs by grouping expenses for similarly tagged resources.

You can tag the following Amazon RDS resources:

- DB instances
- DB clusters
- Read replicas
- DB snapshots
- DB cluster snapshots
- Reserved DB instances
- Event subscriptions
- DB option groups
- DB parameter groups
- DB cluster parameter groups
- DB security groups
- DB subnet groups

Overview of Amazon RDS resource tags

An Amazon RDS tag is a name-value pair that you define and associate with an Amazon RDS resource. The name is referred to as the key. Supplying a value for the key is optional. You can use tags to assign arbitrary information to an Amazon RDS resource. You can use a tag key, for example, to define a category, and the tag value might be an item in that category. For example, you might define a tag key of "project" and a tag value of "Salix", indicating that the Amazon RDS resource is assigned to the Salix project. You can also use tags to designate Amazon RDS resources as being used for test or production by using a key such as `environment=test` or `environment=production`. We recommend that you use a consistent set of tag keys to make it easier to track metadata associated with Amazon RDS resources.

Each Amazon RDS resource has a tag set, which contains all the tags that are assigned to that Amazon RDS resource. A tag set can contain as many as 50 tags, or it can be empty. If you add a tag to an Amazon

RDS resource that has the same key as an existing tag on resource, the new value overwrites the old value.

AWS does not apply any semantic meaning to your tags; tags are interpreted strictly as character strings. Amazon RDS can set tags on a DB instance or other Amazon RDS resources, depending on the settings that you use when you create the resource. For example, Amazon RDS might add a tag indicating that a DB instance is for production or for testing.

- The tag key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with "aws:" or "rds:". The string can contain only the set of Unicode letters, digits, white-space, '_', ':', ';', '/', '=', '+', '-', '@' (Java regex: "`^([\u00p{L}\u00p{Z}\u00p{N}_:=+\u00p{-@\u00p{J}])$`").
- The tag value is an optional string value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with "aws:". The string can contain only the set of Unicode letters, digits, white-space, '_', ':', ';', '/', '=', '+', '-', '@' (Java regex: "`^([\u00p{L}\u00p{Z}\u00p{N}_:=+\u00p{-@\u00p{J}])$`").

Values do not have to be unique in a tag set and can be null. For example, you can have a key-value pair in a tag set of `project=Trinity` and `cost-center=Trinity`.

You can use the AWS Management Console, the command line interface, or the Amazon RDS API to add, list, and delete tags on Amazon RDS resources. When using the command line interface or the Amazon RDS API, you must provide the Amazon Resource Name (ARN) for the Amazon RDS resource you want to work with. For more information about constructing an ARN, see [Constructing an ARN for Amazon RDS \(p. 309\)](#).

Tags are cached for authorization purposes. Because of this, additions and updates to tags on Amazon RDS resources can take several minutes before they are available.

Using tags for access control with IAM

You can use tags with IAM policies to manage access to Amazon RDS resources and to control what actions can be applied to the Amazon RDS resources.

For information on managing access to tagged resources with IAM policies, see [Identity and access management in Amazon RDS \(p. 1644\)](#).

Using tags to produce detailed billing reports

You can also use tags to track costs by grouping expenses for similarly tagged resources.

Use tags to organize your AWS bill to reflect your own cost structure. To do this, sign up to get your AWS account bill with tag key values included. Then, to see the cost of combined resources, organize your billing information according to resources with the same tag key values. For example, you can tag several resources with a specific application name, and then organize your billing information to see the total cost of that application across several services. For more information, see [Using Cost Allocation Tags in the AWS Billing and Cost Management User Guide](#).

Note

You can add a tag to a snapshot, however, your bill will not reflect this grouping.

Adding, listing, and removing tags

The following procedures show how to perform typical tagging operations on resources related to DB instances.

Console

The process to tag an Amazon RDS resource is similar for all resources. The following procedure shows how to tag an Amazon RDS DB instance.

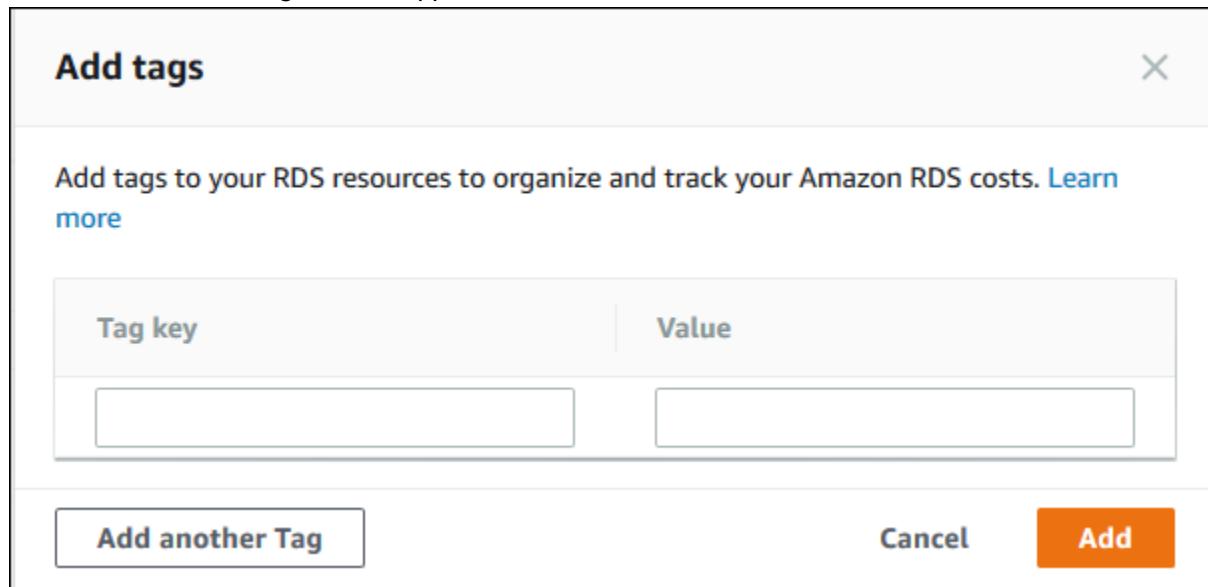

To add a tag to a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.

Note

To filter the list of DB instances in the **Databases** pane, enter a text string for **Filter databases**. Only DB instances that contain the string appear.

3. Choose the name of the DB instance that you want to tag to show its details.
4. In the details section, scroll down to the **Tags** section.
5. Choose **Add**. The **Add tags** window appears.

6. Enter a value for **Tag key** and **Value**.
7. To add another tag, you can choose **Add another Tag** and enter a value for its **Tag key** and **Value**.
Repeat this step as many times as necessary.
8. Choose **Add**.

To delete a tag from a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.

Note

To filter the list of DB instances in the **Databases** pane, enter a text string in the **Filter databases** box. Only DB instances that contain the string appear.

3. Choose the name of the DB instance to show its details.
4. In the details section, scroll down to the **Tags** section.

5. Choose the tag you want to delete.

The screenshot shows a table titled "Tags (1)". It has two columns: "Tag key" and "Value". A single row is selected, showing "workload-type" in the "Tag key" column and "other" in the "Value" column. At the top right of the table, there are three buttons: "Edit", "Delete", and "Add". Above the table, there is a search bar labeled "Filter tag key" and a page navigation area with a magnifying glass icon, the number "1", and arrows.

6. Choose **Delete**, and then choose **Delete** in the **Delete tags** window.

AWS CLI

You can add, list, or remove tags for a DB instance using the AWS CLI.

- To add one or more tags to an Amazon RDS resource, use the AWS CLI command [add-tags-to-resource](#).
- To list the tags on an Amazon RDS resource, use the AWS CLI command [list-tags-for-resource](#).
- To remove one or more tags from an Amazon RDS resource, use the AWS CLI command [remove-tags-from-resource](#).

To learn more about how to construct the required ARN, see [Constructing an ARN for Amazon RDS \(p. 309\)](#).

RDS API

You can add, list, or remove tags for a DB instance using the Amazon RDS API.

- To add a tag to an Amazon RDS resource, use the [AddTagsToResource](#) operation.
- To list tags that are assigned to an Amazon RDS resource, use the [ListTagsForResource](#).
- To remove tags from an Amazon RDS resource, use the [RemoveTagsFromResource](#) operation.

To learn more about how to construct the required ARN, see [Constructing an ARN for Amazon RDS \(p. 309\)](#).

When working with XML using the Amazon RDS API, tags use the following schema:

```
<Tagging>
  <TagSet>
    <Tag>
      <Key>Project</Key>
      <Value>Trinity</Value>
    </Tag>
    <Tag>
      <Key>User</Key>
      <Value>Jones</Value>
    </Tag>
  </TagSet>
</Tagging>
```

The following table provides a list of the allowed XML tags and their characteristics. Values for Key and Value are case-dependent. For example, project=Trinity and PROJECT=Trinity are two distinct tags.

Tagging element	Description
TagSet	A tag set is a container for all tags assigned to an Amazon RDS resource. There can be only one tag set per resource. You work with a TagSet only through the Amazon RDS API.
Tag	A tag is a user-defined key-value pair. There can be from 1 to 50 tags in a tag set.
Key	A key is the required name of the tag. The string value can be from 1 to 128 Unicode characters in length and cannot be prefixed with "rds:" or "aws:". The string can only contain only the set of Unicode letters, digits, white-space, '_', '.', '/', '=', '+', '-' (Java regex: " $^([\u0000-\uFFFF][\u0000-\uFFFF]*[\u0000-\uFFFF]_::=+[\u0000-\uFFFF]*)$$ "). Keys must be unique to a tag set. For example, you cannot have a key-pair in a tag set with the key the same but with different values, such as project/Trinity and project/Xanadu.
Value	A value is the optional value of the tag. The string value can be from 1 to 256 Unicode characters in length and cannot be prefixed with "rds:" or "aws:". The string can only contain only the set of Unicode letters, digits, white-space, '_', '.', '/', '=', '+', '-' (Java regex: " $^([\u0000-\uFFFF][\u0000-\uFFFF]*[\u0000-\uFFFF]_::=+[\u0000-\uFFFF]*)$$ "). Values do not have to be unique in a tag set and can be null. For example, you can have a key-value pair in a tag set of project/Trinity and cost-center/Trinity.

Using the AWS Tag Editor

You can browse and edit the tags on your RDS resources in the AWS Management Console by using the AWS Tag editor. For more information, see [Tag Editor](#) in the *AWS Resource Groups User Guide*.

Copying tags to DB instance snapshots

When you create or restore a DB instance, you can specify that the tags from the DB instance are copied to snapshots of the DB instance. Copying tags ensures that the metadata for the DB snapshots matches that of the source DB instance and any access policies for the DB snapshot also match those of the source DB instance. Tags are not copied by default.

You can specify that tags are copied to DB snapshots for the following actions:

- Creating a DB instance.
- Restoring a DB instance.
- Creating a read replica.
- Copying a DB snapshot.

Note

If you include a value for the `--tag-key` parameter of the `create-db-snapshot` AWS CLI command (or supply at least one tag to the [CreateDBSnapshot](#) API operation) then RDS doesn't copy tags from the source DB instance to the new DB snapshot. This functionality applies even if the source DB instance has the `--copy-tags-to-snapshot` (`CopyTagsToSnapshot`) option enabled. If you take this approach, you can create a copy of a DB instance from a DB snapshot and avoid adding tags that don't apply to the new DB instance. Once you have created your DB

snapshot using the AWS CLI `create-db-snapshot` command (or the `CreateDBSnapshot` Amazon RDS API operation) you can then add tags as described later in this topic.

Tutorial: Use tags to specify which DB instances to stop

Suppose that you're creating a number of DB instances in a development or test environment. You need to keep all of these DB instances for several days. Some of the DB instances run tests overnight. Other DB instances can be stopped overnight and started again the next day. The following example shows how to assign a tag to those DB instances that are suitable to stop overnight. Then the example shows how a script can detect which DB instances have that tag and then stop those DB instances. In this example, the value portion of the key-value pair doesn't matter. The presence of the `stoppable` tag signifies that the DB instance has this user-defined property.

To specify which DB instances to stop

1. Determine the ARN of a DB instance that you want to designate as stoppable.

The commands and APIs for tagging work with ARNs. That way, they can work seamlessly across AWS Regions, AWS accounts, and different types of resources that might have identical short names. You can specify the ARN instead of the DB instance ID in CLI commands that operate on DB instances. Substitute the name of your own DB instances for `dev-test-db-instance`. In subsequent commands that use ARN parameters, substitute the ARN of your own DB instance. The ARN includes your own AWS account ID and the name of the AWS Region where your DB instance is located.

```
$ aws rds describe-db-instances --db-instance-id dev-test-db-instance \
--query "[].{DBInstance:DBInstanceArn}" --output text
arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance
```

2. Add the tag `stoppable` to this DB instance.

The name for this tag is chosen by you. Using a tag like this is an alternative to devising a naming convention that encodes all the relevant information in the name of the DB instance (or other types of resources). Because this example treats the tag as an attribute that is either present or absent, it omits the `Value=` part of the `--tags` parameter.

```
$ aws rds add-tags-to-resource \
--resource-name arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance \
--tags Key=stoppable
```

3. Confirm that the tag is present in the DB instance.

These commands retrieve the tag information for the DB instance in JSON format and in plain tab-separated text.

```
$ aws rds list-tags-for-resource \
--resource-name arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance
{
    "TagList": [
        {
            "Key": "stoppable",
            "Value": ""
        }
    ]
}
aws rds list-tags-for-resource \
```

```
--resource-name arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance --output
text
TAGLIST stoppable
```

4. To stop all the DB instances that are designated as stoppable, prepare a list of all your DB instances. Loop through the list and check if each DB instance is tagged with the relevant attribute.

This Linux example uses shell scripting to save the list of DB instance ARNs to a temporary file and then perform CLI commands for each DB instance.

```
$ aws rds describe-db-instances --query "[].{DBInstanceArn}" --output text >/tmp/
db_instance_arns.lst
$ for arn in $(cat /tmp/db_instance_arns.lst)
do
    match=$(aws rds list-tags-for-resource --resource-name $arn --output text | grep
stoppable)"
    if [[ ! -z "$match" ]]
    then
        echo "DB instance $arn is tagged as stoppable. Stopping it now."
# Note that you need to get the DB instance identifier from the ARN.
        dbid=$(echo $arn | sed -e 's/.*/::/')
        aws rds stop-db-instance --db-instance-identifier $dbid
    fi
done

DB instance arn:arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance is tagged as
stoppable. Stopping it now.
{
    "DBInstance": {
        "DBInstanceIdentifier": "dev-test-db-instance",
        "DBInstanceClass": "db.t3.medium",
        ...
    }
}
```

You can run a script like this at the end of each day to make sure that nonessential DB instances are stopped. You might also schedule a job using a utility such as cron to perform such a check each night, in case some DB instances were left running by mistake. In that case, you might fine-tune the command that prepares the list of DB instances to check. The following command produces a list of your DB instances, but only the ones in available state. The script can ignore DB instances that are already stopped, because they will have different status values such as stopped or stopping.

```
$ aws rds describe-db-instances \
--query '[].{DBInstanceArn:DBInstanceArn,DBInstanceStatus:DBInstanceStatus}|[?
DBInstanceStatus == `available`]|[].{DBInstanceArn:DBInstanceArn}' \
--output text
arn:aws:rds:us-east-1:123456789102:db:db-instance-2447
arn:aws:rds:us-east-1:123456789102:db:db-instance-3395
arn:aws:rds:us-east-1:123456789102:db:dev-test-db-instance
arn:aws:rds:us-east-1:123456789102:db:pg2-db-instance
```

Tip

Once you're familiar with the general procedure of assigning tags and finding DB instances that have those tags, you can use the same technique to reduce costs in other ways. For example, in this scenario with DB instances used for development and testing, you might designate some DB instances to be deleted at the end of each day, or to have their DB instances changed to a small DB instance classes during times of expected low usage.

Using tags to enable backups in AWS Backup

AWS Backup is a fully managed backup service that makes it easy to centralize and automate the backup of data across AWS services in the cloud and on premises. You can manage backups of your Amazon RDS DB instances in AWS Backup.

To enable backups in AWS Backup, you use resource tagging to associate your DB instance with a backup plan.

This example assumes that you have already created a backup plan in AWS Backup. You use exactly the same tag for your DB instance that is in your backup plan, as shown in the following figure.

Backup plan tags (1)		Edit	Delete	Add
<input type="text"/> Filter by tags				« 1 » @
<input type="checkbox"/>	Tag key	Value		
<input type="checkbox"/>	BackupPlan	Test		

For more information about AWS Backup, see the [AWS Backup Developer Guide](#).

You can assign a tag to a DB instance using the AWS Management Console, the AWS CLI, or the RDS API. The following examples are for the console and CLI.

Console

To assign a tag to a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the link for the DB instance to which you want to assign a tag.
4. On the database details page, choose the **Tags** tab.
5. Under **Tags**, choose **Add tags**.
6. Under **Add tags**:
 - a. For **Tag key**, enter **BackupPlan**.
 - b. For **Value**, enter **Test**.
 - c. Choose **Add**.

The result is shown under **Tags**.

Key	Value
BackupPlan	Test

CLI

To assign a tag to a DB instance

- Use the following CLI command:

For Linux, macOS, or Unix:

```
aws rds add-tags-to-resource \
--resource-name arn:aws:rds:us-east-1:123456789012:db:new-orcl-db \
--tags Key=BackupPlan,Value=Test
```

For Windows:

```
aws rds add-tags-to-resource ^
--resource-name arn:aws:rds:us-east-1:123456789012:db:new-orcl-db ^
--tags Key=BackupPlan,Value=Test
```

The `add-tags-to-resource` CLI command returns no output.

To confirm that the DB instance is tagged

- Use the following CLI command:

For Linux, macOS, or Unix:

```
aws rds list-tags-for-resource \
--resource-name arn:aws:rds:us-east-1:123456789012:db:new-orcl-db
```

For Windows:

```
aws rds list-tags-for-resource ^
--resource-name arn:aws:rds:us-east-1:123456789012:db:new-orcl-db
```

The `list-tags-for-resource` CLI command returns the following output:

```
{  
    "TagList": [  
        {  
            "Key": "BackupPlan",  
            "Value": "Test"  
        }  
    ]  
}
```

Working with Amazon Resource Names (ARNs) in Amazon RDS

Resources created in Amazon Web Services are each uniquely identified with an Amazon Resource Name (ARN). For certain Amazon RDS operations, you must uniquely identify an Amazon RDS resource by specifying its ARN. For example, when you create an RDS DB instance read replica, you must supply the ARN for the source DB instance.

Constructing an ARN for Amazon RDS

Resources created in Amazon Web Services are each uniquely identified with an Amazon Resource Name (ARN). You can construct an ARN for an Amazon RDS resource using the following syntax.

`arn:aws:rds:<region>:<account number>:<resourcetype>:<name>`

Region Name	Region	Endpoint	Protocol	
US East (Ohio)	us-east-2	rds.us-east-2.amazonaws.com rds-fips.us-east-2.amazonaws.com	HTTPS HTTPS	
US East (N. Virginia)	us-east-1	rds.us-east-1.amazonaws.com rds-fips.us-east-1.amazonaws.com	HTTPS HTTPS	
US West (N. California)	us-west-1	rds.us-west-1.amazonaws.com rds-fips.us-west-1.amazonaws.com	HTTPS HTTPS	
US West (Oregon)	us-west-2	rds.us-west-2.amazonaws.com rds-fips.us-west-2.amazonaws.com	HTTPS HTTPS	
Africa (Cape Town)	af-south-1	rds.af-south-1.amazonaws.com	HTTPS	
Asia Pacific (Hong Kong)	ap-east-1	rds.ap-east-1.amazonaws.com	HTTPS	
Asia Pacific (Mumbai)	ap-south-1	rds.ap-south-1.amazonaws.com	HTTPS	
Asia Pacific (Osaka)	ap-northeast-3	rds.ap-northeast-3.amazonaws.com	HTTPS	
Asia Pacific (Seoul)	ap-northeast-2	rds.ap-northeast-2.amazonaws.com	HTTPS	

Region Name	Region	Endpoint	Protocol	
Asia Pacific (Singapore)	ap-southeast-1	rds.ap-southeast-1.amazonaws.com	HTTPS	
Asia Pacific (Sydney)	ap-southeast-2	rds.ap-southeast-2.amazonaws.com	HTTPS	
Asia Pacific (Tokyo)	ap-northeast-1	rds.ap-northeast-1.amazonaws.com	HTTPS	
Canada (Central)	ca-central-1	rds.ca-central-1.amazonaws.com rds-fips.ca-central-1.amazonaws.com	HTTPS HTTPS	
China (Beijing)	cn-north-1	rds.cn-north-1.amazonaws.com.cn	HTTPS	
China (Ningxia)	cn-northwest-1	rds.cn-northwest-1.amazonaws.com.cn	HTTPS	
Europe (Frankfurt)	eu-central-1	rds.eu-central-1.amazonaws.com	HTTPS	
Europe (Ireland)	eu-west-1	rds.eu-west-1.amazonaws.com	HTTPS	
Europe (London)	eu-west-2	rds.eu-west-2.amazonaws.com	HTTPS	
Europe (Milan)	eu-south-1	rds.eu-south-1.amazonaws.com	HTTPS	
Europe (Paris)	eu-west-3	rds.eu-west-3.amazonaws.com	HTTPS	
Europe (Stockholm)	eu-north-1	rds.eu-north-1.amazonaws.com	HTTPS	
Middle East (Bahrain)	me-south-1	rds.me-south-1.amazonaws.com	HTTPS	
South America (São Paulo)	sa-east-1	rds.sa-east-1.amazonaws.com	HTTPS	
AWS GovCloud (US-East)	us-gov-east-1	rds.us-gov-east-1.amazonaws.com	HTTPS	
AWS GovCloud (US-West)	us-gov-west-1	rds.us-gov-west-1.amazonaws.com	HTTPS	

The following table shows the format that you should use when constructing an ARN for a particular Amazon RDS resource type.

Resource type	ARN format
DB instance	<p>arn:aws:rds:<region>:<account>:db:<name></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:db:my-mysql-instance-1</pre>
Event subscription	<p>arn:aws:rds:<region>:<account>:es:<name></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:es:my-subscription</pre>
DB option group	<p>arn:aws:rds:<region>:<account>:og:<name></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:og:my-og</pre>
DB parameter group	<p>arn:aws:rds:<region>:<account>:pg:<name></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:pg:my-param-enable-logs</pre>
Reserved DB instance	<p>arn:aws:rds:<region>:<account>:ri:<name></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:ri:my-reserved-postgresql</pre>
DB security group	<p>arn:aws:rds:<region>:<account>:secgrp:<name></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:secgrp:my-public</pre>
Automated DB snapshot	<p>arn:aws:rds:<region>:<account>:snapshot:rds:<name></p> <p>For example:</p> <pre>arn:aws:rds:us-east-2:123456789012:snapshot:rds:my-mysql-db-2019-07-22-07-23</pre>
Manual DB snapshot	<p>arn:aws:rds:<region>:<account>:snapshot:<name></p> <p>For example:</p>

Resource type	ARN format
	<code>arn:aws:rds:<i>us-east-2</i>:<i>123456789012</i>:snapshot:<i>my-mysql-db-snap</i></code>
DB subnet group	<code>arn:aws:rds:<region>:<account>:subgrp:<name></code> For example: <code>arn:aws:rds:<i>us-east-2</i>:<i>123456789012</i>:subgrp:<i>my-subnet-10</i></code>

Getting an existing ARN

You can get the ARN of an RDS resource by using the AWS Management Console, AWS Command Line Interface (AWS CLI), or RDS API.

Console

To get an ARN from the AWS Management Console, navigate to the resource you want an ARN for, and view the details for that resource. For example, you can get the ARN for a DB instance from the **Configuration** tab of the DB instance details, as shown following.

Connectivity Monitoring Logs & events Configuration

Instance

Configuration

DB instance id
oracle-instance1

Engine version
12.1.0.2.v14

Storage type
General Purpose (SSD)

IOPS
-

Storage
20 GiB

DB name
ORCL

License model
Bring Your Own License

Character set
AL32UTF8

Option groups
default:oracle-ee-12-1

ARN
arn:aws:rds:us-west-2:XXXXXXXXXX:db:oracle-instance1

Resource id

AWS CLI

To get an ARN from the AWS CLI for a particular RDS resource, you use the `describe` command for that resource. The following table shows each AWS CLI command, and the ARN property used with the command to get an ARN.

AWS CLI command	ARN property
<code>describe-event-subscriptions</code>	<code>EventSubscriptionArn</code>
<code>describe-certificates</code>	<code>CertificateArn</code>

AWS CLI command	ARN property
describe-db-parameter-groups	DBParameterGroupArn
describe-db-instances	DBInstanceArn
describe-db-security-groups	DBSecurityGroupArn
describe-db-snapshots	DBSnapshotArn
describe-events	SourceArn
describe-reserved-db-instances	ReservedDBInstanceArn
describe-db-subnet-groups	DBSubnetGroupArn
describe-option-groups	OptionGroupArn

For example, the following AWS CLI command gets the ARN for a DB instance.

Example

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
--db-instance-identifier DBInstanceIdentifier \
--region us-west-2 \
--query "[].{DBInstanceIdentifier:DBInstanceIdentifier,DBInstanceArn:DBInstanceArn}"
```

For Windows:

```
aws rds describe-db-instances ^
--db-instance-identifier DBInstanceIdentifier ^
--region us-west-2 ^
--query "[].{DBInstanceIdentifier:DBInstanceIdentifier,DBInstanceArn:DBInstanceArn}"
```

The output of that command is like the following:

```
[  
  {  
    "DBInstanceArn": "arn:aws:rds:us-west-2:account_id:db:instance_id",  
    "DBInstanceIdentifier": "instance_id"  
  }  
]
```

RDS API

To get an ARN for a particular RDS resource, you can call the following RDS API operations and use the ARN properties shown following.

RDS API operation	ARN property
DescribeEventSubscriptions	EventSubscriptionArn
DescribeCertificates	CertificateArn

RDS API operation	ARN property
DescribeDBParameterGroups	DBParameterGroupArn
DescribeDBInstances	DBInstanceArn
DescribeDBSecurityGroups	DBSecurityGroupArn
DescribeDBSchemas	DBSnapshotArn
DescribeEvents	SourceArn
DescribeReservedDBInstances	ReservedDBInstanceArn
DescribeDBSubnetGroups	DBSubnetGroupArn
DescribeOptionGroups	OptionGroupArn

Working with storage for Amazon RDS DB instances

To specify how you want your data stored in Amazon RDS, choose a storage type and provide a storage size when you create or modify a DB instance. Later, you can increase the amount or change the type of storage by modifying the DB instance. For more information about which storage type to use for your workload, see [Amazon RDS storage types \(p. 40\)](#).

Topics

- [Increasing DB instance storage capacity \(p. 316\)](#)
- [Managing capacity automatically with Amazon RDS storage autoscaling \(p. 317\)](#)
- [Modifying SSD storage settings for Provisioned IOPS \(p. 322\)](#)

Increasing DB instance storage capacity

If you need space for additional data, you can scale up the storage of an existing DB instance. To do so, you can use the Amazon RDS Management Console, the Amazon RDS API, or the AWS Command Line Interface (AWS CLI). For information about storage limits, see [Amazon RDS DB instance storage \(p. 40\)](#).

Note

Scaling storage for Amazon RDS for Microsoft SQL Server DB instances is supported only for General Purpose SSD or Provisioned IOPS SSD storage types.

To monitor the amount of free storage for your DB instance so you can respond when necessary, we recommend that you create an Amazon CloudWatch alarm. For more information on setting CloudWatch alarms, see [Using CloudWatch alarms](#).

In most cases, scaling storage doesn't require any outage and doesn't degrade performance of the server. After you modify the storage size for a DB instance, the status of the DB instance is **storage-optimization**. The DB instance is fully operational after a storage modification.

Note

You can't make further storage modifications until six (6) hours after storage optimization has completed on the instance.

However, a special case is if you have a SQL Server DB instance and haven't modified the storage configuration since November 2017. In this case, you might experience a short outage of a few minutes when you modify your DB instance to increase the allocated storage. After the outage, the DB instance is online but in the **storage-optimization** state. Performance might be degraded during storage optimization.

Note

You can't reduce the amount of storage for a DB instance after storage has been allocated. When you increase the allocated storage, it must be by at least 10 percent. If you try to increase the value by less than 10 percent, you get an error.

Console

To increase storage for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.

3. Choose the DB instance that you want to modify.
4. Choose **Modify**.
5. Enter a new value for **Allocated storage**. It must be greater than the current value.

The screenshot shows the 'Storage type' dropdown set to 'General Purpose (SSD)'. Below it, the 'Allocated storage' input field contains '16384 GiB'. A note below the input says 'This instance supports multiple storage ranges between 20 and 16384 GiB.' with a 'See all' link. A warning box contains the text: 'Scaling your instance storage can:' followed by two bullet points: 'Deplete the initial General Purpose (SSD) I/O credits, leading to longer conversion times.' and 'Impact instance performance until operation completes.'

6. Choose **Continue** to move to the next screen.
7. Choose **Apply immediately** in the **Scheduling of modifications** section to apply the storage changes to the DB instance immediately. Or choose **Apply during the next scheduled maintenance window** to apply the changes during the next maintenance window.
8. When the settings are as you want them, choose **Modify DB instance**.

AWS CLI

To increase the storage for a DB instance, use the AWS CLI command `modify-db-instance`. Set the following parameters:

- `--allocated-storage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `--apply-immediately` – Use `--apply-immediately` to change to the new storage type immediately. Or use `--no-apply-immediately` (the default) to apply storage changes during the next maintenance window. An immediate outage occurs when the changes are applied.

For more information about storage, see [Amazon RDS DB instance storage \(p. 40\)](#).

Amazon RDS API

To increase storage for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameters:

- `AllocatedStorage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `ApplyImmediately` – Set this option to `True` to apply scaling changes immediately. Set this option to `False` (the default) to apply scaling changes during the next maintenance window. An immediate outage occurs when the changes are applied.

For more information about storage, see [Amazon RDS DB instance storage \(p. 40\)](#).

Managing capacity automatically with Amazon RDS storage autoscaling

If your workload is unpredictable, you can enable storage autoscaling for an Amazon RDS DB instance. To do so, you can use the Amazon RDS console, the Amazon RDS API, or the AWS CLI.

For example, you might use this feature for a new mobile gaming application that users are adopting rapidly. In this case, a rapidly increasing workload might exceed the available database storage. To avoid having to manually scale up database storage, you can use Amazon RDS storage autoscaling.

With storage autoscaling enabled, when Amazon RDS detects that you are running out of free database space it automatically scales up your storage. Amazon RDS starts a storage modification for an autoscaling-enabled DB instance when these factors apply:

- Free available space is less than 10 percent of the allocated storage.
- The low-storage condition lasts at least five minutes.
- At least six hours have passed since the last storage modification.

The additional storage is in increments of whichever of the following is greater:

- 5 GiB
- 10 percent of currently allocated storage
- Storage growth prediction for 7 hours based on the `FreeStorageSpace` metrics change in the past hour. For more information on metrics, see [Monitoring with Amazon CloudWatch](#).

The maximum storage threshold is the limit that you set for autoscaling the DB instance. You can't set the maximum storage threshold for autoscaling-enabled instances to a value greater than the maximum allocated storage.

For example, SQL Server Standard Edition on db.m5.xlarge has a default allocated storage for the instance of 20 GiB (the minimum) and a maximum allocated storage of 16,384 GiB. The default maximum storage threshold for autoscaling is 1,000 GiB. If you use this default, the instance doesn't autoscale above 1,000 GiB. This is true even though the maximum allocated storage for the instance is 16,384 GiB.

Note

We recommend that you carefully choose the maximum storage threshold based on usage patterns and customer needs. If there are any aberrations in the usage patterns, the maximum storage threshold can prevent scaling storage to an unexpectedly high value when autoscaling predicts a very high threshold. After a DB instance has been autoscaled, its allocated storage can't be reduced.

The following limitations apply to storage autoscaling:

- Autoscaling doesn't occur if the maximum storage threshold would be exceeded by the storage increment.
- Autoscaling can't completely prevent storage-full situations for large data loads, because further storage modifications can't be made until six hours after storage optimization has completed on the instance. If you perform a large data load, and autoscaling doesn't provide enough space, the database might remain in the storage-full state for several hours. This can harm the database.
- If you start a storage scaling operation at the same time that Amazon RDS starts an autoscaling operation, your storage modification takes precedence. The autoscaling operation is canceled.
- Autoscaling can't be used with magnetic storage.
- Autoscaling can't be used with the following previous-generation instance classes that have less than 6 TiB of orderable storage: db.m3.large, db.m3.xlarge, and db.m3.2xlarge.
- Autoscaling operations aren't logged by AWS CloudTrail. For more information on CloudTrail, see [Working with AWS CloudTrail and Amazon RDS \(p. 557\)](#).

Although automatic scaling helps you to increase storage on your Amazon RDS DB instance dynamically, you should still configure the initial storage for your DB instance to an appropriate size for your typical workload.

Enabling storage autoscaling for a new DB instance

When you create a new Amazon RDS DB instance, you can choose whether to enable storage autoscaling. You can also set an upper limit on the storage that Amazon RDS can allocate for the DB instance.

Note

When you clone an Amazon RDS DB instance that has storage autoscaling enabled, that setting isn't automatically inherited by the cloned instance. The new DB instance has the same amount of allocated storage as the original instance. You can turn storage autoscaling on again for the new instance if the cloned instance continues to increase its storage requirements.

Console

To enable storage autoscaling for a new DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region where you want to create the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose **Create database**. On the **Select engine** page, choose your database engine and specify your DB instance information as described in [Getting started with Amazon RDS \(p. 73\)](#).
5. In the **Storage autoscaling** section, set the **Maximum storage threshold** value for the DB instance.
6. Specify the rest of your DB instance information as described in [Getting started with Amazon RDS \(p. 73\)](#).

AWS CLI

To enable storage autoscaling for a new DB instance, use the AWS CLI command `create-db-instance`. Set the following parameter:

- `--max-allocated-storage` – Turns on storage autoscaling and sets the upper limit on storage size, in gibibytes.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the AWS CLI `describe-valid-db-instance-modifications` command. To check based on the instance class before creating an instance, use the `describe-orderable-db-instance-options` command. Check the following field in the return value:

- `SupportsStorageAutoscaling` – Indicates whether the DB instance or instance class supports storage autoscaling.

For more information about storage, see [Amazon RDS DB instance storage \(p. 40\)](#).

Amazon RDS API

To enable storage autoscaling for a new DB instance, use the Amazon RDS API operation `CreateDBInstance`. Set the following parameter:

- `MaxAllocatedStorage` – Turns on Amazon RDS storage autoscaling and sets the upper limit on storage size, in gibibytes.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the Amazon RDS API `DescribeValidDbInstanceModifications` operation for an existing instance, or the

[DescribeOrderableDBInstanceOptions](#) operation before creating an instance. Check the following field in the return value:

- `SupportsStorageAutoscaling` – Indicates whether the DB instance supports storage autoscaling.

For more information about storage, see [Amazon RDS DB instance storage \(p. 40\)](#).

Changing the storage autoscaling settings for a DB instance

You can turn storage autoscaling on for an existing Amazon RDS DB instance. You can also change the upper limit on the storage that Amazon RDS can allocate for the DB instance.

Console

To change the storage autoscaling settings for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify, and choose **Modify**. The **Modify DB instance** page appears.
4. Change the storage limit in the **Autoscaling** section. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).
5. When all the changes are as you want them, choose **Continue** and check your modifications.
6. On the confirmation page, review your changes. If they're correct, choose **Modify DB Instance** to save your changes. If they aren't correct, choose **Back** to edit your changes or **Cancel** to cancel your changes.

Changing the storage autoscaling limit occurs immediately. This setting ignores the **Apply immediately** setting.

AWS CLI

To change the storage autoscaling settings for a DB instance, use the AWS CLI command `modify-db-instance`. Set the following parameter:

- `--max-allocated-storage` – Sets the upper limit on storage size, in gibibytes. If the value is greater than the `--allocated-storage` parameter, storage autoscaling is turned on. If the value is the same as the `--allocated-storage` parameter, storage autoscaling is turned off.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the AWS CLI `describe-valid-db-instance-modifications` command. To check based on the instance class before creating an instance, use the `describe-orderable-db-instance-options` command. Check the following field in the return value:

- `SupportsStorageAutoscaling` – Indicates whether the DB instance supports storage autoscaling.

For more information about storage, see [Amazon RDS DB instance storage \(p. 40\)](#).

Amazon RDS API

To change the storage autoscaling settings for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameter:

- `MaxAllocatedStorage` – Sets the upper limit on storage size, in gibibytes.

To verify that Amazon RDS storage autoscaling is available for your DB instance, use the Amazon RDS API [DescribeValidDbInstanceModifications](#) operation for an existing instance, or the [DescribeOrderableDBInstanceOptions](#) operation before creating an instance. Check the following field in the return value:

- `SupportsStorageAutoscaling` – Indicates whether the DB instance supports storage autoscaling.

For more information about storage, see [Amazon RDS DB instance storage \(p. 40\)](#).

Turning off storage autoscaling for a DB instance

If you no longer need Amazon RDS to automatically increase the storage for an Amazon RDS DB instance, you can turn off storage autoscaling. After you do, you can still manually increase the amount of storage for your DB instance.

Console

To turn off storage autoscaling for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify and choose **Modify**. The **Modify DB instance** page appears.
4. Clear the **Enable storage autoscaling** check box in the **Storage autoscaling** section. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).
5. When all the changes are as you want them, choose **Continue** and check the modifications.
6. On the confirmation page, review your changes. If they're correct, choose **Modify DB Instance** to save your changes. If they aren't correct, choose **Back** to edit your changes or **Cancel** to cancel your changes.

Changing the storage autoscaling limit occurs immediately. This setting ignores the **Apply immediately** setting.

AWS CLI

To turn off storage autoscaling for a DB instance, use the AWS CLI command `modify-db-instance` and the following parameter:

- `--max-allocated-storage` – Specify a value equal to the `--allocated-storage` setting to prevent further Amazon RDS storage autoscaling for the specified DB instance.

For more information about storage, see [Amazon RDS DB instance storage \(p. 40\)](#).

Amazon RDS API

To turn off storage autoscaling for a DB instance, use the Amazon RDS API operation `ModifyDBInstance`. Set the following parameter:

- `MaxAllocatedStorage` – Specify a value equal to the `AllocatedStorage` setting to prevent further Amazon RDS storage autoscaling for the specified DB instance.

For more information about storage, see [Amazon RDS DB instance storage \(p. 40\)](#).

Modifying SSD storage settings for Provisioned IOPS

You can modify the settings for a DB instance that uses Provisioned IOPS SSD storage by using the Amazon RDS console, AWS CLI, or Amazon RDS API. Specify the storage type, allocated storage, and the amount of Provisioned IOPS that you require. You can choose from a range between 1,000 IOPS and 100 GiB of storage up to 80,000 IOPS and 64 TiB (64,000 GiB) of storage. The range depends on your database engine and instance type.

Although you can reduce the amount of IOPS provisioned for your instance, you can't reduce the amount of General Purpose SSD or magnetic storage allocated.

In most cases, scaling storage doesn't require any outage and doesn't degrade performance of the server. After you modify the storage IOPS for a DB instance, the status of the DB instance is **storage-optimization**. The DB instance is fully operational after a storage modification.

Note

You can't make further storage modifications until six (6) hours after storage optimization has completed on the instance.

Console

To change the Provisioned IOPS settings for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.

Note

To filter the list of DB instances, for **Filter databases** enter a text string for Amazon RDS to use to filter the results. Only DB instances whose names contain the string appear.

3. Choose the DB instance with Provisioned IOPS that you want to modify.
4. Choose **Modify**.
5. On the **Modify DB Instance page**, choose Provisioned IOPS for **Storage type** and then provide a Provisioned IOPS value.

The screenshot shows the 'Modify DB Instance' page with the following fields:

- Storage type:** A dropdown menu set to "Provisioned IOPS (SSD)".
- Allocated storage:** An input field containing "16384" with a unit indicator "GiB". Below it, a note says "Minimum: 100 GiB, Maximum: 16384".
- Provisioned IOPS:** An input field containing "80000". To its left is a link "Info".

If the value you specify for either **Allocated storage** or **Provisioned IOPS** is outside the limits supported by the other parameter, a warning message is displayed. This message gives the range of values required for the other parameter.

6. Choose **Continue**.
7. To apply the changes to the DB instance immediately, choose **Apply immediately** in the **Scheduling of modifications** section. Or choose **Apply during the next scheduled maintenance window** to apply the changes during the next maintenance window.

An immediate outage occurs when the storage type changes. For more information about storage, see [Amazon RDS DB instance storage \(p. 40\)](#).

8. Review the parameters to be changed, and choose **Modify DB instance** to complete the modification.

The new value for allocated storage or for Provisioned IOPS appears in the **Status** column.

AWS CLI

To change the Provisioned IOPS setting for a DB instance, use the AWS CLI command [modify-db-instance](#). Set the following parameters:

- `--storage-type` – Set to `io1` for Provisioned IOPS.
- `--allocated-storage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `--iops` – The new amount of Provisioned IOPS for the DB instance, expressed in I/O operations per second.
- `--apply-immediately` – Use `--apply-immediately` to apply changes immediately. Use `--no-apply-immediately` (the default) to apply changes during the next maintenance window.

Amazon RDS API

To change the Provisioned IOPS settings for a DB instance, use the Amazon RDS API operation [ModifyDBInstance](#). Set the following parameters:

- `StorageType` – Set to `io1` for Provisioned IOPS.
- `AllocatedStorage` – Amount of storage to be allocated for the DB instance, in gibibytes.
- `Iops` – The new IOPS rate for the DB instance, expressed in I/O operations per second.
- `ApplyImmediately` – Set this option to `True` to apply changes immediately. Set this option to `False` (the default) to apply changes during the next maintenance window.

Deleting a DB instance

To delete a DB instance, you must do the following:

- Provide the name of the instance
- Enable or disable the option to take a final DB snapshot of the instance
- Enable or disable the option to retain automated backups

If the DB instance that you want to delete has a read replica, you should either promote the read replica or delete it. For more information, see [Promoting a read replica to be a standalone DB instance \(p. 285\)](#).

Note

When the status for a DB instance is `deleting`, its CA certificate value doesn't appear in the RDS console or in output for AWS CLI commands or RDS API operations. For more information about CA certificates, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 1634\)](#).

Deletion protection

You can only delete instances that don't have deletion protection enabled. When you create or modify a DB instance, you have the option to enable deletion protection so that users can't delete the DB instance. Deletion protection is disabled by default for you when you use AWS CLI and API commands. Deletion protection is enabled for you when you use the AWS Management Console to create a production DB instance. However, Amazon RDS enforces deletion protection when you use the console, the CLI, or the API to delete a DB instance. To delete a DB instance that has deletion protection enabled, first modify the instance and disable deletion protection. Enabling or disabling deletion protection doesn't cause an outage.

Creating a final snapshot and retaining automated backups

When you delete a DB instance, you can choose to do one or both of the following:

- Create a final DB snapshot.
 - To be able to restore your deleted DB instance later, create a final DB snapshot. The final snapshot is retained, along with any manual snapshots that were taken.
 - To delete a DB instance quickly, you can skip creating a final DB snapshot.

Note

You can't create a final DB snapshot of your DB instance if it has the status `creating`, `failed`, `incompatible-restore`, or `incompatible-network`. For more information, see [DB instance status \(p. 404\)](#).

- Retain automated backups.
 - Your automated backups are retained for the retention period that is set on the DB instance at the time when you delete it. This set retention period occurs whether or not you choose to create a final DB snapshot.
 - If you don't choose to retain automated backups, your automated backups in the same AWS Region as the DB instance are deleted. They can't be recovered after you delete the DB instance.

Note

Automated backups that are replicated to another AWS Region are retained even if you choose not to retain automated backups. For more information, see [Replicating automated backups to another AWS Region \(p. 338\)](#).

- You typically don't need to retain automated backups if you create a final DB snapshot.

- To delete a retained automated backup, follow the instructions in [Deleting retained automated backups \(p. 333\)](#).

Important

If you skip the final DB snapshot, to restore your DB instance do one of the following:

- Use an earlier manual snapshot of the DB instance to restore the DB instance to that DB snapshot's point in time.
- Retain automated backups. You can use them to restore your DB instance during your retention period, but not after your retention period has ended.

Note

Regardless of your choice, manual DB snapshots aren't deleted. For more information on snapshots, see [Creating a DB snapshot \(p. 346\)](#).

Deleting a DB instance

You can delete a DB instance using the AWS Management Console, the AWS CLI, or the RDS API.

The time required to delete a DB instance can vary depending on the backup retention period (that is, how many backups to delete), how much data is deleted, and whether a final snapshot is taken.

Note

You can't delete a DB instance when deletion protection is enabled for it. For more information, see [Deletion protection \(p. 324\)](#).

You can disable deletion protection by modifying the DB instance. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

Console

To delete a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to delete.
3. For **Actions**, choose **Delete**.
4. To create a final DB snapshot for the DB instance, choose **Create final snapshot?**.
5. If you chose to create a final snapshot, enter the **Final snapshot name**.
6. To retain automated backups, choose **Retain automated backups**.
7. Enter **delete me** in the box.
8. Choose **Delete**.

AWS CLI

To delete a DB instance by using the AWS CLI, call the `delete-db-instance` command with the following options:

- `--db-instance-identifier`
- `--final-db-snapshot-identifier` or `--skip-final-snapshot`

Example With a final snapshot and no retained automated backups

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
--db-instance-identifier mydbinstance \
--final-db-snapshot-identifier mydbinstancefinalsnapshot \
--delete-automated-backups
```

For Windows:

```
aws rds delete-db-instance ^
--db-instance-identifier mydbinstance ^
--final-db-snapshot-identifier mydbinstancefinalsnapshot ^
--delete-automated-backups
```

Example With retained automated backups and no final snapshot

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \
--db-instance-identifier mydbinstance \
--skip-final-snapshot \
--no-delete-automated-backups
```

For Windows:

```
aws rds delete-db-instance ^
--db-instance-identifier mydbinstance ^
--skip-final-snapshot ^
--no-delete-automated-backups
```

RDS API

To delete a DB instance by using the Amazon RDS API, call the [DeleteDBInstance](#) operation with the following parameters:

- `DBInstanceIdentifier`
- `FinalDBSnapshotIdentifier` or `SkipFinalSnapshot`

Backing up and restoring an Amazon RDS DB instance

This section shows how to back up and restore a DB instance.

Topics

- [Replicating automated backups to another AWS Region \(p. 338\)](#)
- [Creating a DB snapshot \(p. 346\)](#)
- [Restoring from a DB snapshot \(p. 349\)](#)
- [Copying a snapshot \(p. 352\)](#)
- [Sharing a DB snapshot \(p. 365\)](#)
- [Exporting DB snapshot data to Amazon S3 \(p. 373\)](#)
- [Restoring a DB instance to a specified time \(p. 389\)](#)
- [Deleting a snapshot \(p. 392\)](#)
- [Tutorial: Restore a DB instance from a DB snapshot \(p. 394\)](#)

Working with backups

Amazon RDS creates and saves automated backups of your DB instance during the backup window of your DB instance. RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. RDS saves the automated backups of your DB instance according to the backup retention period that you specify. If necessary, you can recover your database to any point in time during the backup retention period.

Automated backups follow these rules:

- Your DB instance must be in the `AVAILABLE` state for automated backups to occur. Automated backups don't occur while your DB instance is in a state other than `AVAILABLE`, for example `STORAGE_FULL`.
- Automated backups and automated snapshots don't occur while a copy is running in the same AWS Region for the same DB instance.

You can also back up your DB instance manually, by manually creating a DB snapshot. For more information about creating a DB snapshot, see [Creating a DB snapshot \(p. 346\)](#).

The first snapshot of a DB instance contains the data for the full DB instance. Subsequent snapshots of the same DB instance are incremental, which means that only the data that has changed after your most recent snapshot is saved.

You can copy both automatic and manual DB snapshots, and share manual DB snapshots. For more information about copying a DB snapshot, see [Copying a snapshot \(p. 352\)](#). For more information about sharing a DB snapshot, see [Sharing a DB snapshot \(p. 365\)](#).

Backup storage

Your Amazon RDS backup storage for each AWS Region is composed of the automated backups and manual DB snapshots for that Region. Total backup storage space equals the sum of the storage for all backups in that Region. Moving a DB snapshot to another Region increases the backup storage in the destination Region. Backups are stored in Amazon S3.

For more information about backup storage costs, see [Amazon RDS pricing](#).

If you chose to retain automated backups when you delete a DB instance, the automated backups are saved for the full retention period. If you don't choose **Retain automated backups** when you delete a DB instance, all automated backups are deleted with the DB instance. After they are deleted, the automated backups can't be recovered. If you choose to have Amazon RDS create a final DB snapshot before it deletes your DB instance, you can use that to recover your DB instance. Or you can use a previously created manual snapshot. Manual snapshots are not deleted. You can have up to 100 manual snapshots per Region.

Backup window

Automated backups occur daily during the preferred backup window. If the backup requires more time than allotted to the backup window, the backup continues after the window ends, until it finishes. The backup window can't overlap with the weekly maintenance window for the DB instance.

During the automatic backup window, storage I/O might be suspended briefly while the backup process initializes (typically under a few seconds). You might experience elevated latencies for a few minutes during backups for Multi-AZ deployments. For MariaDB, MySQL, Oracle, and PostgreSQL, I/O activity is not suspended on your primary during backup for Multi-AZ deployments, because the backup is

taken from the standby. For SQL Server, I/O activity is suspended briefly during backup for Multi-AZ deployments.

If you don't specify a preferred backup window when you create the DB instance, Amazon RDS assigns a default 30-minute backup window. This window is selected at random from an 8-hour block of time for each AWS Region. The following table lists the time blocks for each AWS Region from which the default backup windows are assigned.

Region Name	Region	Time Block
US East (Ohio)	us-east-2	03:00–11:00 UTC
US East (N. Virginia)	us-east-1	03:00–11:00 UTC
US West (N. California)	us-west-1	06:00–14:00 UTC
US West (Oregon)	us-west-2	06:00–14:00 UTC
Africa (Cape Town)	af-south-1	03:00–11:00 UTC
Asia Pacific (Hong Kong)	ap-east-1	06:00–14:00 UTC
Asia Pacific (Mumbai)	ap-south-1	16:30–00:30 UTC
Asia Pacific (Osaka)	ap-northeast-3	00:00–08:00 UTC
Asia Pacific (Seoul)	ap-northeast-2	13:00–21:00 UTC
Asia Pacific (Singapore)	ap-southeast-1	14:00–22:00 UTC
Asia Pacific (Sydney)	ap-southeast-2	12:00–20:00 UTC
Asia Pacific (Tokyo)	ap-northeast-1	13:00–21:00 UTC
Canada (Central)	ca-central-1	03:00–11:00 UTC
China (Beijing)	cn-north-1	06:00–14:00 UTC
China (Ningxia)	cn-northwest-1	06:00–14:00 UTC
Europe (Frankfurt)	eu-central-1	20:00–04:00 UTC
Europe (Ireland)	eu-west-1	22:00–06:00 UTC
Europe (London)	eu-west-2	22:00–06:00 UTC
Europe (Paris)	eu-west-3	07:29–14:29 UTC
Europe (Milan)	eu-south-1	02:00–10:00 UTC
Europe (Stockholm)	eu-north-1	23:00–07:00 UTC
Middle East (Bahrain)	me-south-1	06:00–14:00 UTC
South America (São Paulo)	sa-east-1	23:00–07:00 UTC
AWS GovCloud (US-East)	us-gov-east-1	17:00–01:00 UTC

Region Name	Region	Time Block
AWS GovCloud (US-West)	us-gov-west-1	06:00–14:00 UTC

Backup retention period

You can set the backup retention period when you create a DB instance. If you don't set the backup retention period, the default backup retention period is one day if you create the DB instance using the Amazon RDS API or the AWS CLI. The default backup retention period is seven days if you create the DB instance using the console.

After you create a DB instance, you can modify the backup retention period. You can set the backup retention period to between 0 and 35 days. Setting the backup retention period to 0 disables automated backups. Manual snapshot limits (100 per Region) do not apply to automated backups.

Automated backups aren't created while a DB instance is stopped. Backups can be retained longer than the backup retention period if a DB instance has been stopped. RDS doesn't include time spent in the stopped state when the backup retention window is calculated.

Important

An outage occurs if you change the backup retention period from 0 to a nonzero value or from a nonzero value to 0. This applies to both Single-AZ and Multi-AZ DB instances.

Enabling automated backups

If your DB instance doesn't have automated backups enabled, you can enable them at any time. You enable automated backups by setting the backup retention period to a positive nonzero value. When automated backups are enabled, your RDS instance and database is taken offline and a backup is immediately created.

Note

If you manage your backups in AWS Backup, you can't enable automated backups. For more information, see [Using AWS Backup to manage automated backups \(p. 335\)](#).

Console

To enable automated backups immediately

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. For **Backup retention period**, choose a positive nonzero value, for example 3 days.
5. Choose **Continue**.
6. Choose **Apply immediately**.
7. On the confirmation page, choose **Modify DB instance** to save your changes and enable automated backups.

AWS CLI

To enable automated backups, use the AWS CLI `modify-db-instance` command.

Include the following parameters:

- `--db-instance-identifier`
- `--backup-retention-period`
- `--apply-immediately` or `--no-apply-immediately`

In the following example, we enable automated backups by setting the backup retention period to three days. The changes are applied immediately.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --backup-retention-period 3 \
  --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --backup-retention-period 3 ^
  --apply-immediately
```

RDS API

To enable automated backups, use the RDS API [ModifyDBInstance](#) operation with the following required parameters:

- `DBInstanceIdentifier`
- `BackupRetentionPeriod`

Retaining automated backups

When you delete a DB instance, you can retain automated backups.

Retained automated backups contain system snapshots and transaction logs from a DB instance. They also include your DB instance properties like allocated storage and DB instance class, which are required to restore it to an active instance.

You can retain automated backups for RDS instances running the MySQL, MariaDB, PostgreSQL, Oracle, and Microsoft SQL Server engines.

You can restore or remove retained automated backups using the AWS Management Console, RDS API, and AWS CLI.

Topics

- [Retention period \(p. 332\)](#)
- [Viewing retained backups \(p. 332\)](#)
- [Restoration \(p. 332\)](#)
- [Retention costs \(p. 332\)](#)
- [Limitations and recommendations \(p. 333\)](#)

Retention period

The system snapshots and transaction logs in a retained automated backup expire the same way that they expire for the source DB instance. Because there are no new snapshots or logs created for this instance, the retained automated backups eventually expire completely. Effectively, they live as long their last system snapshot would have done, based on the settings for retention period the source instance had when you deleted it. Retained automated backups are removed by the system after their last system snapshot expires.

You can remove a retained automated backup in the same way that you can delete a DB instance. You can remove retained automated backups using the console or the RDS API operation `DeleteDBInstanceAutomatedBackup`.

Final snapshots are independent of retained automated backups. We strongly suggest that you take a final snapshot even if you retain automated backups, because the retained automated backups eventually expire. The final snapshot doesn't expire.

Viewing retained backups

To view your retained automated backups, switch to the automated backups page. You can view individual snapshots associated with a retained automated backup on the database snapshots page in the console. Alternatively, you can describe individual snapshots associated with a retained automated backup. From there, you can restore a DB instance directly from one of those snapshots.

To describe your retained automated backups using the AWS CLI, use one of the following commands:

```
aws rds describe-db-instance-automated-backups --db-instance-  
identifier DBInstanceIdentifier
```

or

```
aws rds describe-db-instance-automated-backups --dbi-resource-id DbiResourceId
```

To describe your retained automated backups using the RDS API, call the `DescribeDBInstanceAutomatedBackups` action with one of the following parameters:

- `DBInstanceIdentifier`
- `DbiResourceId`

Restoration

For information on restoring DB instances from automated backups, see [Restoring a DB instance to a specified time \(p. 389\)](#).

Retention costs

The cost of a retained automated backup is the cost of total storage of the system snapshots that are associated with it. There is no additional charge for transaction logs or instance metadata. All other pricing rules for backups apply to restorable instances.

For example, suppose that your total allocated storage of running instances is 100 GB. Suppose also that you have 50 GB of manual snapshots plus 75 GB of system snapshots associated with a retained automated backup. In this case, you are charged only for the additional 25 GB of backup storage, like this: $(50 \text{ GB} + 75 \text{ GB}) - 100 \text{ GB} = 25 \text{ GB}$.

Limitations and recommendations

The following limitations apply to retained automated backups:

- The maximum number of retained automated backups in one AWS Region is 40. It's not included in the DB instances limit. You can have 40 running DB instances and an additional 40 retained automated backups at the same time.
- Retained automated backups don't contain information about parameters or option groups.
- You can restore a deleted instance to a point in time that is within the retention period at the time of delete.
- You can't modify a retained automated backup. That's because it consists of system backups, transaction logs, and the DB instance properties that existed at the time that you deleted the source instance.

Deleting retained automated backups

You can delete retained automated backups when they are no longer needed.

Console

To delete a retained automated backup

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Automated backups**.
3. On the **Retained** tab, choose the retained automated backup that you want to delete.
4. For **Actions**, choose **Delete**.
5. On the confirmation page, enter **delete me** and choose **Delete**.

AWS CLI

You can delete a retained automated backup by using the AWS CLI command `delete-db-instance-automated-backup` with the following option:

- `--dbi-resource-id` – The resource identifier for the source DB instance.

You can find the resource identifier for the source DB instance of a retained automated backup by running the AWS CLI command `describe-db-instance-automated-backups`.

Example

The following example deletes the retained automated backup with source DB instance resource identifier `db-123ABCEXAMPLE`.

For Linux, macOS, or Unix:

```
aws rds delete-db-instance-automated-backup \
--dbi-resource-id db-123ABCEXAMPLE
```

For Windows:

```
aws rds delete-db-instance-automated-backup ^
```

```
--dbi-resource-id db-123ABCEXAMPLE
```

RDS API

You can delete a retained automated backup by using the Amazon RDS API operation [DeleteDBInstanceAutomatedBackup](#) with the following parameter:

- **DbiResourceId** – The resource identifier for the source DB instance.

You can find the resource identifier for the source DB instance of a retained automated backup using the Amazon RDS API operation [DescribeDBInstanceAutomatedBackups](#).

Disabling automated backups

You might want to temporarily disable automated backups in certain situations, for example while loading large amounts of data.

Important

We highly discourage disabling automated backups because it disables point-in-time recovery. Disabling automatic backups for a DB instance deletes all existing automated backups for the instance. If you disable and then re-enable automated backups, you can restore starting only from the time you re-enabled automated backups.

Console

To disable automated backups immediately

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**. The **Modify DB instance** page appears.
4. For **Backup retention period**, choose **0 days**.
5. Choose **Continue**.
6. Choose **Apply immediately**.
7. On the confirmation page, choose **Modify DB instance** to save your changes and disable automated backups.

AWS CLI

To disable automated backups immediately, use the `modify-db-instance` command and set the backup retention period to 0 with `--apply-immediately`.

Example

The following example immediately disabled automatic backups.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--backup-retention-period 0 \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--backup-retention-period 0 ^
--apply-immediately
```

To know when the modification is in effect, call `describe-db-instances` for the DB instance until the value for backup retention period is 0 and *mydbinstance* status is available.

```
aws rds describe-db-instances --db-instance-identifier mydbinstance
```

RDS API

To disable automated backups immediately, call the [ModifyDBInstance](#) operation with the following parameters:

- `DBInstanceIdentifier = mydbinstance`
- `BackupRetentionPeriod = 0`

Example

```
https://rds.amazonaws.com/
?Action=ModifyDBInstance
&DBInstanceIdentifier=mydbinstance
&BackupRetentionPeriod=0
&SignatureVersion=2
&SignatureMethod=HmacSHA256
&Timestamp=2009-10-14T17%3A48%3A21.746Z
&AWSAccessKeyId=<AWS Access Key ID>
&Signature=<Signature>
```

Using AWS Backup to manage automated backups

AWS Backup is a fully managed backup service that makes it easy to centralize and automate the backup of data across AWS services in the cloud and on premises. You can manage backups of your Amazon RDS DB instances in AWS Backup.

To enable backups in AWS Backup, you use resource tagging to associate your DB instance with a backup plan. For more information, see [Using tags to enable backups in AWS Backup \(p. 306\)](#).

Note

Backups managed by AWS Backup are considered manual DB snapshots, but don't count toward the DB snapshot quota for RDS. Backups that were created with AWS Backup have names ending in `awsbackup :AWS-Backup-job-number`.

For more information about AWS Backup, see the [AWS Backup Developer Guide](#).

To view backups managed by AWS Backup

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the **Backup service** tab.

Your AWS Backup backups are listed under **Backup service snapshots**.

Automated backups with unsupported MySQL storage engines

For the MySQL DB engine, automated backups are only supported for the InnoDB storage engine. Use of these features with other MySQL storage engines, including MyISAM, can lead to unreliable behavior while restoring from backups. Specifically, since storage engines like MyISAM don't support reliable crash recovery, your tables can be corrupted in the event of a crash. For this reason, we encourage you to use the InnoDB storage engine.

- To convert existing MyISAM tables to InnoDB tables, you can use the `ALTER TABLE` command, for example: `ALTER TABLE table_name ENGINE=innodb, ALGORITHM=COPY;`
- If you choose to use MyISAM, you can attempt to manually repair tables that become damaged after a crash by using the `REPAIR` command. For more information, see [REPAIR TABLE statement](#) in the MySQL documentation. However, as noted in the MySQL documentation, there is a good chance that you might not be able to recover all your data.
- If you want to take a snapshot of your MyISAM tables before restoring, follow these steps:
 1. Stop all activity to your MyISAM tables (that is, close all sessions).

You can close all sessions by calling the `mysql.rds_kill` command for each process that is returned from the `SHOW FULL PROCESSLIST` command.

2. Lock and flush each of your MyISAM tables. For example, the following commands lock and flush two tables named `myisam_table1` and `myisam_table2`:

```
mysql> FLUSH TABLES myisam_table, myisam_table2 WITH READ LOCK;
```

3. Create a snapshot of your DB instance. When the snapshot has completed, release the locks and resume activity on the MyISAM tables. You can release the locks on your tables using the following command:

```
mysql> UNLOCK TABLES;
```

These steps force MyISAM to flush data stored in memory to disk, which ensures a clean start when you restore from a DB snapshot. For more information on creating a DB snapshot, see [Creating a DB snapshot \(p. 346\)](#).

Automated backups with unsupported MariaDB storage engines

For the MariaDB DB engine, automated backups are only supported with the InnoDB storage engine (version 10.2 and later) and XtraDB storage engine (versions 10.0 and 10.1). Use of these features with other MariaDB storage engines, including Aria, might lead to unreliable behavior while restoring from backups. Even though Aria is a crash-resistant alternative to MyISAM, your tables can still be corrupted in the event of a crash. For this reason, we encourage you to use the XtraDB storage engine.

- To convert existing Aria tables to InnoDB tables, you can use the `ALTER TABLE` command. For example: `ALTER TABLE table_name ENGINE=innodb, ALGORITHM=COPY;`
- To convert existing Aria tables to XtraDB tables, you can use the `ALTER TABLE` command. For example: `ALTER TABLE table_name ENGINE=xtradb, ALGORITHM=COPY;`
- If you choose to use Aria, you can attempt to manually repair tables that become damaged after a crash by using the `REPAIR TABLE` command. For more information, see <http://mariadb.com/kb/en/mariadb/repair-table/>.

- If you want to take a snapshot of your Aria tables before restoring, follow these steps:
 1. Stop all activity to your Aria tables (that is, close all sessions).
 2. Lock and flush each of your Aria tables.
 3. Create a snapshot of your DB instance. When the snapshot has completed, release the locks and resume activity on the Aria tables. These steps force Aria to flush data stored in memory to disk, thereby ensuring a clean start when you restore from a DB snapshot.

Replicating automated backups to another AWS Region

For added disaster recovery capability, you can configure your Amazon RDS database instance to replicate snapshots and transaction logs to a destination AWS Region of your choice. When backup replication is configured for a DB instance, RDS initiates a cross-Region copy of all snapshots and transaction logs as soon as they are ready on the DB instance.

DB snapshot copy charges apply to the data transfer. After the DB snapshot is copied, standard charges apply to storage in the destination Region. For more details, see [RDS Pricing](#).

Backup replication is available for RDS DB instances running the following database engines:

- Oracle version 12.1.0.2.v10 and higher
- PostgreSQL version 9.6 and higher

Backup replication isn't supported for encrypted DB instances.

Enabling cross-Region automated backups

You can enable backup replication on new or existing DB instances using the Amazon RDS console. You can also use the `start-db-instance-automated-backups-replication` AWS CLI command or the `StartDBInstanceAutomatedBackupsReplication` RDS API operation.

Note

To be able to replicate automated backups, make sure to enable them. For more information, see [Enabling automated backups \(p. 330\)](#).

You can use the `describe-source-regions` CLI command to list the source AWS Regions that can replicate automated backups to a particular destination Region. For more information, see [Finding information about replicated backups \(p. 339\)](#).

Console

You can enable backup replication for a new or existing DB instance:

- For a new DB instance, enable it when you launch the instance. For more information, see [Settings for DB instances \(p. 145\)](#).
- For an existing DB instance, use the following procedure.

To enable backup replication for an existing DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Automated backups**.
3. On the **Current Region** tab, choose the DB instance for which you want to enable backup replication.
4. For **Actions**, choose **Manage cross-Region replication**.
5. Under **Backup replication**, choose **Enable replication to another AWS Region**.
6. Choose the **Destination Region**.
7. Choose the **Replicated backup retention period**.
8. Choose **Save**.

In the source Region, replicated backups are listed on the **Current Region** tab of the **Automated backups** page. In the destination Region, replicated backups are listed on the **Replicated backups** tab of the **Automated backups** page.

AWS CLI

Enable backup replication by using the [start-db-instance-automated-backups-replication](#) AWS CLI command.

The following CLI example replicates automated backups from a DB instance in the US West (Oregon) Region to the US East (N. Virginia) Region.

To enable backup replication

- Run one of the following commands.

For Linux, macOS, or Unix:

```
aws rds start-db-instance-automated-backups-replication \
--region us-east-1 \
--source-db-instance-arn "arn:aws:rds:us-west-2:123456789012:db:mydatabase" \
--backup-retention-period 7
```

For Windows:

```
aws rds start-db-instance-automated-backups-replication ^
--region us-east-1 ^
--source-db-instance-arn "arn:aws:rds:us-west-2:123456789012:db:mydatabase" ^
--backup-retention-period 7
```

RDS API

Enable backup replication by using the [StartDBInstanceAutomatedBackupsReplication](#) RDS API operation with the following parameters:

- Region
- SourceDBInstanceArn
- BackupRetentionPeriod

Finding information about replicated backups

You can use the following CLI commands to find information about replicated backups:

- [describe-source-regions](#)
- [describe-db-instances](#)
- [describe-db-instance-automated-backups](#)

The following `describe-source-regions` example lists the source AWS Regions from which automated backups can be replicated to the US West (Oregon) destination Region.

To show information about source Regions

- Run the following command.

```
aws rds describe-source-regions --region us-west-2
```

The output shows that backups can be replicated from Asia Pacific (Tokyo), but not from Asia Pacific (Seoul), into US West (Oregon).

```
{  
    "SourceRegions": [  
        {  
            "RegionName": "ap-northeast-1",  
            "Endpoint": "https://rds.ap-northeast-1.amazonaws.com",  
            "Status": "available",  
            "SupportsDBInstanceAutomatedBackupsReplication": true  
        },  
        {  
            "RegionName": "ap-northeast-2",  
            "Endpoint": "https://rds.ap-northeast-2.amazonaws.com",  
            "Status": "available",  
            "SupportsDBInstanceAutomatedBackupsReplication": false  
        }  
        ...  
    ]  
}
```

The following `describe-db-instances` example shows the automated backups for a DB instance.

To show the replicated backups for a DB instance

- Run one of the following commands.

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \  
--db-instance-identifier mydatabase
```

For Windows:

```
aws rds describe-db-instances ^  
--db-instance-identifier mydatabase
```

The output includes the replicated backups.

```
{  
    "DBInstances": [  
        {  
            "StorageEncrypted": false,  
            "Endpoint": {  
                "HostedZoneId": "Z1PVIF0B656C1W",  
                "Port": 1521,  
                ...  
            },  
            "BackupRetentionPeriod": 7,  
            "DBInstanceAutomatedBackupsReplications": [{"DBInstanceAutomatedBackupsArn":  
"arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEEXAMPLE"}]  
        }  
    ]  
}
```

The following `describe-db-instance-automated-backups` example shows the automated backups for a DB instance.

To show automated backups for a DB instance

- Run one of the following commands.

For Linux, macOS, or Unix:

```
aws rds describe-db-instance-automated-backups \
--db-instance-identifier mydatabase
```

For Windows:

```
aws rds describe-db-instance-automated-backups ^
--db-instance-identifier mydatabase
```

The output shows the source DB instance and automated backups in US West (Oregon), with backups replicated to US East (N. Virginia).

```
{
    "DBInstanceAutomatedBackups": [
        {
            "DBInstanceArn": "arn:aws:rds:us-west-2:868710585169:db:mydatabase",
            "DbiResourceId": "db-L2IJCEXJP7XQ7HOJ4SIEEXAMPLE",
            "DBInstanceAutomatedBackupsArn": "arn:aws:rds:us-west-2:123456789012:auto-
backup:ab-L2IJCEXJP7XQ7HOJ4SIEEXAMPLE",
            "BackupRetentionPeriod": 7,
            "DBInstanceAutomatedBackupsReplications": [{"DBInstanceAutomatedBackupsArn": "
"arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEEXAMPLE"}]
            "Region": "us-west-2",
            "DBInstanceIdentifier": "mydatabase",
            "RestoreWindow": {
                "EarliestTime": "2020-10-26T01:09:07Z",
                "LatestTime": "2020-10-31T19:09:53Z",
            }
            ...
        }
    ]
}
```

The following `describe-db-instance-automated-backups` example uses the `--db-instance-automated-backups-arn` option to show the replicated backups in the destination Region.

To show replicated backups

- Run one of the following commands.

For Linux, macOS, or Unix:

```
aws rds describe-db-instance-automated-backups \
--db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-
L2IJCEXJP7XQ7HOJ4SIEEXAMPLE"
```

For Windows:

```
aws rds describe-db-instance-automated-backups ^
```

```
--db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEEXAMPLE"
```

The output shows the source DB instance in US West (Oregon), with replicated backups in US East (N. Virginia).

```
{  
    "DBInstanceAutomatedBackups": [  
        {  
            "DBInstanceArn": "arn:aws:rds:us-west-2:868710585169:db:mydatabase",  
            "DbiResourceId": "db-L2IJCEXJP7XQ7HOJ4SIEEXAMPLE",  
            "DBInstanceAutomatedBackupsArn": "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEEXAMPLE",  
            "Region": "us-west-2",  
            "DBInstanceIdentifier": "mydatabase",  
            "RestoreWindow": {  
                "EarliestTime": "2020-10-26T01:09:07Z",  
                "LatestTime": "2020-10-31T19:01:23Z"  
            },  
            "AllocatedStorage": 50,  
            "BackupRetentionPeriod": 7,  
            "Status": "replicating",  
            "Port": 1521,  
            ...  
        }  
    ]  
}
```

Restoring to a specified time from a replicated backup

You can restore a DB instance to a specific point in time from a replicated backup using the Amazon RDS console. You can also use the `restore-db-instance-to-point-in-time` AWS CLI command or the `RestoreDBInstanceToPointInTime` RDS API operation.

For general information on point-in-time recovery (PITR), see [Restoring a DB instance to a specified time \(p. 389\)](#).

Console

To restore a DB instance to a specified time from a replicated backup

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose the destination Region (where backups are replicated to) from the Region selector.
3. In the navigation pane, choose **Automated backups**.
4. On the **Replicated backups** tab, choose the DB instance that you want to restore.
5. For **Actions**, choose **Restore to point in time**.
6. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

If you chose **Custom**, enter the date and time that you want to restore the instance to.

Note

Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.

7. For **DB instance identifier**, enter the name of the target restored DB instance.
8. (Optional) Choose other options as needed, such as enabling autoscaling.
9. Choose **Restore to point in time**.

AWS CLI

Use the `restore-db-instance-to-point-in-time` AWS CLI command to create a new DB instance.

To restore a DB instance to a specified time from a replicated backup

- Run one of the following commands.

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-to-point-in-time \
    --source-db-instance-automated-backups-arn "arn:aws:rds:us-
east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEEXAMPLE" \
    --target-db-instance-identifier mytargetdbinstance \
    --restore-time 2020-10-14T23:45:00.000Z
```

For Windows:

```
aws rds restore-db-instance-to-point-in-time ^
    --source-db-instance-automated-backups-arn "arn:aws:rds:us-
east-1:123456789012:auto-backup:ab-L2IJCEXJP7XQ7HOJ4SIEEXAMPLE" ^
    --target-db-instance-identifier mytargetdbinstance ^
    --restore-time 2020-10-14T23:45:00.000Z
```

RDS API

To restore a DB instance to a specified time, call the `RestoreDBInstanceToPointInTime` Amazon RDS API operation with the following parameters:

- `SourceDBInstanceAutomatedBackupsArn`
- `TargetDBInstanceIdentifier`
- `RestoreTime`

Stopping automated backup replication

You can stop backup replication for DB instances using the Amazon RDS console. You can also use the `stop-db-instance-automated-backups-replication` AWS CLI command or the `StopDBInstanceAutomatedBackupsReplication` RDS API operation.

Replicated backups are retained, subject to the backup retention period set when they were created.

Console

Stop backup replication from the **Automated backups** page in the source Region.

To stop backup replication to an AWS Region

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. Choose the source Region from the **Region selector**.
3. In the navigation pane, choose **Automated backups**.
4. On the **Current Region** tab, choose the DB instance for which you want to stop backup replication.
5. For **Actions**, choose **Manage cross-Region replication**.
6. Under **Backup replication**, clear the **Enable replication to another AWS Region** check box.
7. Choose **Save**.

Replicated backups are listed on the **Retained** tab of the **Automated backups** page in the destination Region.

AWS CLI

Stop backup replication by using the `stop-db-instance-automated-backups-replication` AWS CLI command.

The following CLI example stops automated backups of a DB instance from replicating in the US West (Oregon) Region.

To stop backup replication

- Run one of the following commands.

For Linux, macOS, or Unix:

```
aws rds stop-db-instance-automated-backups-replication \
--region us-east-1 \
--source-db-instance-arn "arn:aws:rds:us-west-2:123456789012:db:mydatabase"
```

For Windows:

```
aws rds stop-db-instance-automated-backups-replication ^
--region us-east-1 ^
--source-db-instance-arn "arn:aws:rds:us-west-2:123456789012:db:mydatabase"
```

RDS API

Stop backup replication by using the `StopDBInstanceAutomatedBackupsReplication` RDS API operation with the following parameters:

- `Region`
- `SourceDBInstanceArn`

Deleting replicated backups

You can delete replicated backups for DB instances using the Amazon RDS console. You can also use the `delete-db-instance-automated-backups` AWS CLI command or the `DeleteDBInstanceAutomatedBackup` RDS API operation.

Console

Delete replicated backups in the destination Region from the **Automated backups** page.

To delete replicated backups

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose the destination Region from the **Region selector**.
3. In the navigation pane, choose **Automated backups**.
4. On the **Replicated backups** tab, choose the DB instance for which you want to delete the replicated backups.
5. For **Actions**, choose **Delete**.
6. On the confirmation page, enter **delete me** and choose **Delete**.

AWS CLI

Delete replicated backups by using the `delete-db-instance-automated-backup` AWS CLI command.

You can use the `describe-db-instances` CLI command to find the Amazon Resource Names (ARNs) of the replicated backups. For more information, see [Finding information about replicated backups \(p. 339\)](#).

To delete replicated backups

- Run one of the following commands.

For Linux, macOS, or Unix:

```
aws rds delete-db-instance-automated-backup \
--db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-
L2IJCEXJP7XQ7HOJ4SIEEXAMPLE"
```

For Windows:

```
aws rds delete-db-instance-automated-backup ^
--db-instance-automated-backups-arn "arn:aws:rds:us-east-1:123456789012:auto-backup:ab-
L2IJCEXJP7XQ7HOJ4SIEEXAMPLE"
```

RDS API

Delete replicated backups by using the `DeleteDBInstanceAutomatedBackup` RDS API operation with the `DBInstanceAutomatedBackupsArn` parameter.

Creating a DB snapshot

Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. Creating this DB snapshot on a Single-AZ DB instance results in a brief I/O suspension that can last from a few seconds to a few minutes, depending on the size and class of your DB instance. For MariaDB, MySQL, Oracle, and PostgreSQL, I/O activity is not suspended on your primary during backup for Multi-AZ deployments, because the backup is taken from the standby. For SQL Server, I/O activity is suspended briefly during backup for Multi-AZ deployments.

When you create a DB snapshot, you need to identify which DB instance you are going to back up, and then give your DB snapshot a name so you can restore from it later. The amount of time it takes to create a snapshot varies with the size of your databases. Since the snapshot includes the entire storage volume, the size of files, such as temporary files, also affects the amount of time it takes to create the snapshot.

Note

For PostgreSQL DB instances, data in unlogged tables might not be restored from snapshots. For more information, see [Best practices for working with PostgreSQL \(p. 137\)](#).

Unlike automated backups, manual snapshots aren't subject to the backup retention period. Snapshots don't expire.

For very long-term backups of MariaDB, MySQL, and PostgreSQL data, we recommend exporting snapshot data to Amazon S3. If the major version of your DB engine is no longer supported, you can't restore to that version from a snapshot. For more information, see [Exporting DB snapshot data to Amazon S3 \(p. 373\)](#).

You can create a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To create a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. In the list of DB instances, choose the DB instance for which you want to take a snapshot.
4. For **Actions**, choose **Take snapshot**.

The **Take DB Snapshot** window appears.

5. Type the name of the snapshot in the **Snapshot Name** box.

Take DB Snapshot

This feature is currently supported for InnoDB storage engine only. If you are using MyISAM, refer to details [here](#). 

Settings

To take a snapshot of this DB instance you must provide a name for the snapshot.

DB instance

The unique key that identifies a DB instance. This parameter isn't case-sensitive.

`mydbinstance3`

Snapshot name

The Identifier for the DB Snapshot.

[Cancel](#)

[Take Snapshot](#)

- Choose **Take Snapshot**.

AWS CLI

When you create a DB snapshot using the AWS CLI, you need to identify which DB instance you are going to back up, and then give your DB snapshot a name so you can restore from it later. You can do this by using the AWS CLI `create-db-snapshot` command with the following parameters:

- `--db-instance-identifier`
- `--db-snapshot-identifier`

In this example, you create a DB snapshot called `mydbsnapshot` for a DB instance called `mydbinstance`.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \
--db-instance-identifier mydbinstance \
--db-snapshot-identifier mydbsnapshot
```

For Windows:

```
aws rds create-db-snapshot ^
--db-instance-identifier mydbinstance ^
--db-snapshot-identifier mydbsnapshot
```

RDS API

When you create a DB snapshot using the Amazon RDS API, you need to identify which DB instance you are going to back up, and then give your DB snapshot a name so you can restore from it later. You can do this by using the Amazon RDS API `CreateDBSnapshot` command with the following parameters:

- **DBInstanceIdentifier**
- **DBSnapshotIdentifier**

Restoring from a DB snapshot

Amazon RDS creates a storage volume snapshot of your DB instance, backing up the entire DB instance and not just individual databases. You can create a DB instance by restoring from this DB snapshot. When you restore the DB instance, you provide the name of the DB snapshot to restore from, and then provide a name for the new DB instance that is created from the restore. You can't restore from a DB snapshot to an existing DB instance; a new DB instance is created when you restore.

You can restore a DB instance and use a different storage type than the source DB snapshot. In this case, the restoration process is slower because of the additional work required to migrate the data to the new storage type. If you restore to or from magnetic storage, the migration process is the slowest. That's because magnetic storage doesn't have the IOPS capability of Provisioned IOPS or General Purpose (SSD) storage.

Note

You can't restore a DB instance from a DB snapshot that is both shared and encrypted. Instead, you can make a copy of the DB snapshot and restore the DB instance from the copy. For more information, see [Copying a snapshot \(p. 352\)](#).

Parameter group considerations

We recommend that you retain the parameter group for any DB snapshots you create, so that you can associate your restored DB instance with the correct parameter group. You can specify the parameter group when you restore the DB instance.

Security group considerations

When you restore a DB instance, the default security group is associated with the restored instance by default.

Note

- If you're using the Amazon RDS console, you can specify a custom security group to associate with the instance or create a new VPC security group.
- If you're using the AWS CLI, you can specify a custom security group to associate with the instance by including the `--vpc-security-group-ids` option in the `restore-db-instance-from-db-snapshot` command.
- If you're using the Amazon RDS API, you can include the `VpcSecurityGroupIds.VpcSecurityGroupId.N` parameter in the `RestoreDBInstanceFromDBSnapshot` action.

As soon as the restore is complete and your new DB instance is available, you can associate any custom security groups used by the snapshot you restored from. You must apply these changes by modifying the DB instance with the RDS console, the AWS CLI `modify-db-instance` command, or the `ModifyDBInstance` Amazon RDS API operation. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

Option group considerations

When you restore a DB instance, the option group associated with the DB snapshot is associated with the restored DB instance after it is created. For example, if the DB snapshot you are restoring from uses Oracle Transparent Data Encryption, the restored DB instance will use the same option group.

When you assign an option group to a DB instance, the option group is also linked to the supported platform the DB instance is on, either VPC or EC2-Classic (non-VPC). If a DB instance is in a VPC, the

option group associated with the DB instance is linked to that VPC. This means that you can't use the option group assigned to a DB instance if you attempt to restore the instance into a different VPC or onto a different platform. If you restore a DB instance into a different VPC or onto a different platform, you must either assign the default option group to the instance, assign an option group that is linked to that VPC or platform, or create a new option group and assign it to the DB instance. For persistent or permanent options, when restoring a DB instance into a different VPC you must create a new option group that includes the persistent or permanent option.

Microsoft SQL Server considerations

When you restore a Microsoft SQL Server DB snapshot to a new instance, you can always restore to the same edition as your snapshot. In some cases, you can also change the edition of the DB instance. The following are the limitations when you change editions:

- The DB snapshot must have enough storage allocated for the new edition.
- Only the following edition changes are supported:
 - From Standard Edition to Enterprise Edition
 - From Web Edition to Standard Edition or Enterprise Edition
 - From Express Edition to Web Edition, Standard Edition or Enterprise Edition

If you want to change from one edition to a new edition that is not supported by restoring a snapshot, you can try using the native backup and restore feature. SQL Server verifies whether or not your database is compatible with the new edition based on what SQL Server features you have enabled on the database. For more information, see [Importing and exporting SQL Server databases \(p. 671\)](#).

Oracle considerations

If you use Oracle GoldenGate, always retain the parameter group with the compatible parameter. When you restore a DB instance from a DB snapshot, you must specify the parameter group that has a matching or greater compatible parameter value.

You can upgrade a DB snapshot while it is still a DB snapshot, before you restore it. For more information, see [Upgrading an Oracle DB snapshot \(p. 1217\)](#).

Restoring from a snapshot

You can restore a DB instance from a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To restore a DB instance from a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to restore from.
4. For **Actions**, choose **Restore snapshot**.
5. On the **Restore snapshot** page, for **DB instance identifier**, enter the name for your restored DB instance.
6. Choose **Restore DB instance**.

AWS CLI

To restore a DB instance from a DB snapshot, use the AWS CLI command [restore-db-instance-from-db-snapshot](#).

In this example, you restore from a previously created DB snapshot named `mydbsnapshot`. You restore to a new DB instance named `mynewdbinstance`.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
--db-instance-identifier mynewdbinstance \
--db-snapshot-identifier mydbsnapshot
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
--db-instance-identifier mynewdbinstance ^
--db-snapshot-identifier mydbsnapshot
```

This command returns output similar to the following:

```
DBINSTANCE mynewdbinstance db.m3.large MySQL      50          sa           creating  3  n
5.6.40 general-public-license
```

RDS API

To restore a DB instance from a DB snapshot, call the Amazon RDS API function [RestoreDBInstanceFromDBSnapshot](#) with the following parameters:

- `DBInstanceIdentifier`
- `DBSnapshotIdentifier`

Copying a snapshot

With Amazon RDS, you can copy automated or manual DB snapshots. After you copy a snapshot, the copy is a manual snapshot.

You can copy a snapshot within the same AWS Region, you can copy a snapshot across AWS Regions, and you can copy shared snapshots.

Limitations

The following are some limitations when you copy snapshots:

- You can't copy a snapshot to or from the China (Beijing) or China (Ningxia) Regions.
- You can copy a snapshot between AWS GovCloud (US-East) and AWS GovCloud (US-West). However, you can't copy a snapshot between these AWS GovCloud (US) Regions and commercial AWS Regions.
- If you delete a source snapshot before the target snapshot becomes available, the snapshot copy might fail. Verify that the target snapshot has a status of **AVAILABLE** before you delete a source snapshot.
- You can have up to five snapshot copy requests in progress to a single destination Region per account.
- Depending on the AWS Regions involved and the amount of data to be copied, a cross-Region snapshot copy can take hours to complete. In some cases, there might be a large number of cross-Region snapshot copy requests from a given source Region. In such cases, Amazon RDS might put new cross-Region copy requests from that source Region into a queue until some in-progress copies complete. No progress information is displayed about copy requests while they are in the queue. Progress information is displayed when the copy starts.

Snapshot retention

Amazon RDS deletes automated snapshots in several situations:

- At the end of their retention period.
- When you disable automated snapshots for a DB instance.
- When you delete a DB instance.

If you want to keep an automated snapshot for a longer period, copy it to create a manual snapshot, which is retained until you delete it. Amazon RDS storage costs might apply to manual snapshots if they exceed your default storage space.

For more information about backup storage costs, see [Amazon RDS pricing](#).

Copying shared snapshots

You can copy snapshots shared to you by other AWS accounts. In some cases, you might copy an encrypted snapshot that has been shared from another AWS account. In these cases, you must have access to the AWS KMS customer master key (CMK) that was used to encrypt the snapshot.

You can copy a shared DB snapshot across AWS Regions if the snapshot is unencrypted. However, if the shared DB snapshot is encrypted, you can only copy it in the same Region.

Note

Copying shared incremental snapshots in the same AWS Region is supported when they're unencrypted, or encrypted using the same AWS KMS key as the initial full snapshot. If you use a

different KMS key to encrypt subsequent snapshots when copying them, those shared snapshots are full snapshots.

Handling encryption

You can copy a snapshot that has been encrypted using an AWS KMS customer master key (CMK). If you copy an encrypted snapshot, the copy of the snapshot must also be encrypted. If you copy an encrypted snapshot within the same AWS Region, you can encrypt the copy with the same AWS KMS CMK as the original snapshot. Or you can specify a different CMK. If you copy an encrypted snapshot across Regions, you can't use the same AWS KMS CMK for the copy as used for the source snapshot. This is because AWS KMS CMKs are Region-specific. Instead, you must specify an AWS KMS CMK valid in the destination AWS Region.

The source snapshot remains encrypted throughout the copy process. For more information, see [Limitations of Amazon RDS encrypted DB instances \(p. 1632\)](#).

You can also encrypt a copy of an unencrypted snapshot. This way, you can quickly add encryption to a previously unencrypted DB instance.

That is, you can create a snapshot of your DB instance when you are ready to encrypt it. You then create a copy of that snapshot and specify an AWS KMS CMK to encrypt that snapshot copy. You can then restore an encrypted DB instance from the encrypted snapshot.

Incremental snapshot copying

An *incremental* snapshot contains only the data that has changed after the most recent snapshot of the same DB instance. Incremental snapshot copying is faster and results in lower storage costs than full snapshot copying.

Note

When you copy a source snapshot that is a snapshot copy itself, the new copy isn't incremental. This is because the source snapshot copy doesn't include the required metadata for incremental copies.

Whether a snapshot copy is incremental is determined by the most recently completed snapshot copy. If the most recent snapshot copy was deleted, the next copy is a full copy, not an incremental copy. If a copy is still pending when you start another copy, the second copy doesn't start until the first copy finishes.

When you copy a snapshot across AWS accounts, the copy is an incremental copy if the following conditions are met:

- The snapshot was previously copied to the destination account.
- The most recent snapshot copy still exists in the destination account.
- All copies of the snapshot in the destination account are either unencrypted, or were encrypted using the same CMK.

For shared snapshots, copying incremental snapshots across AWS accounts is only supported when they're unencrypted.

For information on copying incremental snapshots across AWS Regions, see [Full and incremental copies \(p. 356\)](#).

Cross-Region snapshot copying

You can copy DB snapshots across AWS Regions. However, there are certain constraints and considerations for cross-Region snapshot copying.

Requesting a cross-Region DB snapshot copy

To communicate with the source Region to request a cross-Region DB snapshot copy, the requester (IAM role or IAM user) must have access to the source DB snapshot and the source Region.

Certain conditions in the requester's IAM policy can cause the request to fail. The following examples assume that you're copying the DB snapshot from US East (Ohio) to US East (N. Virginia). These examples show conditions in the requester's IAM policy that cause the request to fail:

- The requester's policy has a condition for `aws:RequestedRegion`.

```
...
"Effect": "Allow",
"Action": "rds:CopyDBSnapshot",
"Resource": "*",
"Condition": {
    "StringEquals": {
        "aws:RequestedRegion": "us-east-1"
    }
}
```

The request fails because the policy doesn't allow access to the source Region. For a successful request, specify both the source and destination Regions.

```
...
"Effect": "Allow",
"Action": "rds:CopyDBSnapshot",
"Resource": "*",
"Condition": {
    "StringEquals": {
        "aws:RequestedRegion": [
            "us-east-1",
            "us-east-2"
        ]
    }
}
```

- The requester's policy doesn't allow access to the source DB snapshot.

```
...
"Effect": "Allow",
"Action": "rds:CopyDBSnapshot",
"Resource": "arn:aws:rds:us-east-1:123456789012:snapshot:target-snapshot"
...
```

For a successful request, specify both the source and target snapshots.

```
...
"Effect": "Allow",
"Action": "rds:CopyDBSnapshot",
"Resource": [
    "arn:aws:rds:us-east-1:123456789012:snapshot:target-snapshot",
    "arn:aws:rds:us-east-2:123456789012:snapshot:source-snapshot"
]
...
```

- The requester's policy denies `aws:ViaAWSService`.

```
...
"Effect": "Allow",
```

```
"Action": "rds:CopyDBSnapshot",
"Resource": "*",
"Condition": {
    "Bool": {"aws:ViaAWSService": "false"}
}
```

Communication with the source Region is made by RDS on the requester's behalf. For a successful request, don't deny calls made by AWS services.

- The requester's policy has a condition for `aws:SourceVpc` or `aws:SourceVpce`.

These requests might fail because when RDS makes the call to the remote Region, it isn't from the specified VPC or VPC endpoint.

If you need to use one of the previous conditions that would cause a request to fail, you can include a second statement with `aws:CalledVia` in your policy to make the request succeed. For example, you can use `aws:CalledVia` with `aws:SourceVpce` as shown here:

```
...
"Effect": "Allow",
"Action": "rds:CopyDBSnapshot",
"Resource": "*",
"Condition": {
    "Condition" : {
        "ForAnyValue:StringEquals" : {
            "aws:SourceVpce": "vpce-1a2b3c4d"
        }
    }
},
{
    "Effect": "Allow",
    "Action": [
        "rds:CopyDBSnapshot"
    ],
    "Resource": "*",
    "Condition": {
        "ForAnyValue:StringEquals": {
            "aws:CalledVia": [
                "rds.amazonaws.com"
            ]
        }
    }
}
```

For more information, see [Policies and permissions in IAM](#) in the *IAM User Guide*.

Authorizing the snapshot copy

After a cross-Region DB snapshot copy request returns success, RDS starts the copy in the background. An authorization for RDS to access the source snapshot is created. This authorization links the source DB snapshot to the target DB snapshot, and allows RDS to copy only to the specified target snapshot.

The authorization is verified by RDS using the `rds:CrossRegionCommunication` permission in the service-linked IAM role. If the copy is authorized, RDS communicates with the source Region and completes the copy.

RDS doesn't have access to DB snapshots that weren't authorized previously by a `CopyDBSnapshot` request. The authorization is revoked when copying completes.

RDS uses the service-linked role to verify the authorization in the source Region. If you delete the service-linked role during the copy process, the copy fails.

For more information, see [Using service-linked roles in the IAM User Guide](#).

Using AWS Security Token Service credentials

Session tokens from the global AWS Security Token Service (AWS STS) endpoint are valid only in AWS Regions that are enabled by default (commercial Regions). If you use credentials from the `assumeRole` API operation in AWS STS, use the regional endpoint if the source Region is an opt-in Region. Otherwise, the request fails. This happens because your credentials must be valid in both Regions, which is true for opt-in Regions only when the regional AWS STS endpoint is used.

To use the global endpoint, make sure that it's enabled for both Regions in the operations. Set the global endpoint to `Valid in all AWS Regions` in the AWS STS account settings.

The same rule applies to credentials in the presigned URL parameter.

For more information, see [Managing AWS STS in an AWS Region](#) in the *IAM User Guide*.

Latency and multiple copy requests

Depending on the AWS Regions involved and the amount of data to be copied, a cross-Region snapshot copy can take hours to complete.

In some cases, there might be a large number of cross-Region snapshot copy requests from a given source AWS Region. In such cases, Amazon RDS might put new cross-Region copy requests from that source AWS Region into a queue until some in-progress copies complete. No progress information is displayed about copy requests while they are in the queue. Progress information is displayed when the copying starts.

Full and incremental copies

When you copy a snapshot to a different AWS Region from the source snapshot, the first copy is a full snapshot copy, even if you copy an incremental snapshot. A full snapshot copy contains all of the data and metadata required to restore the DB instance. After the first snapshot copy, you can copy incremental snapshots of the same DB instance to the same destination Region within the same AWS account. For more information on incremental snapshots, see [Incremental snapshot copying \(p. 353\)](#).

Incremental snapshot copying across AWS Regions is supported for both unencrypted and encrypted snapshots.

When you copy a snapshot across AWS Regions, the copy is an incremental copy if the following conditions are met:

- The snapshot was previously copied to the destination Region.
- The most recent snapshot copy still exists in the destination Region.
- All copies of the snapshot in the destination Region are either unencrypted, or were encrypted using the same CMK.

Option group considerations

Option groups are specific to the AWS Region that they are created in, and you can't use an option group from one AWS Region in another AWS Region.

When you copy a snapshot across Regions, you can specify a new option group for the snapshot. We recommend that you prepare the new option group before you copy the snapshot. In the destination AWS Region, create an option group with the same settings as the original DB instance. If one already exists in the new AWS Region, you can use that one.

In some cases, you might copy a snapshot and not specify a new option group for the snapshot. In these cases, when you restore the snapshot the DB instance gets the default option group. To give the new DB instance the same options as the original, do the following:

1. In the destination AWS Region, create an option group with the same settings as the original DB instance . If one already exists in the new AWS Region, you can use that one.
2. After you restore the snapshot in the destination AWS Region, modify the new DB instance and add the new or existing option group from the previous step.

Parameter group considerations

When you copy a snapshot across Regions, the copy doesn't include the parameter group used by the original DB instance . When you restore a snapshot to create a new DB instance , that DB instance gets the default parameter group for the AWS Region it is created in. To give the new DB instance the same parameters as the original, do the following:

1. In the destination AWS Region, create a DB parameter group with the same settings as the original DB instance . If one already exists in the new AWS Region, you can use that one.
2. After you restore the snapshot in the destination AWS Region, modify the new DB instance and add the new or existing parameter group from the previous step.

Copying a DB snapshot

Use the procedures in this topic to copy a DB snapshot. For an overview of copying a snapshot, see [Copying a snapshot \(p. 352\)](#)

For each AWS account, you can copy up to five DB snapshots at a time from one AWS Region to another. If you copy a DB snapshot to another AWS Region, you create a manual DB snapshot that is retained in that AWS Region. Copying a DB snapshot out of the source AWS Region incurs Amazon RDS data transfer charges.

For more information about data transfer pricing, see [Amazon RDS pricing](#).

After the DB snapshot copy has been created in the new AWS Region, the DB snapshot copy behaves the same as all other DB snapshots in that AWS Region.

You can copy a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

Console

The following procedure copies an encrypted or unencrypted DB snapshot, in the same AWS Region or across Regions, by using the AWS Management Console.

To copy a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Select the DB snapshot that you want to copy.
4. For **Actions**, choose **Copy snapshot**.

The **Copy snapshot** page appears.

RDS > Snapshots > Copy snapshot

Copy snapshot

Settings

Source DB Snapshot
DB Snapshot Identifier for the snapshot being copied.
db1-snapshot

Destination Region [Info](#)
US West (Oregon)

New DB Snapshot Identifier
DB Snapshot Identifier for the new snapshot

Target Option Group (Optional)
No preference

Copy Tags [Info](#)

i Please note that depending on the amount of data to be copied and the Region you choose, this operation could take several hours to complete and the display on the progress bar could be delayed until setup is complete.

Encryption

Encryption [Info](#)

Enable Encryption
Choose to encrypt the copy of the source DB snapshot. Master key IDs and aliases appear in the list after they have been created using KMS. You cannot remove encryption from an encrypted DB snapshot.

Master key [Info](#)
(default) aws/rds

Account

KMS key ID

Cancel **Copy snapshot**

5. (Optional) To copy the DB snapshot to a different AWS Region, for **Destination Region**, choose the new AWS Region.

Note

The destination AWS Region must have the same database engine version available as the source AWS Region.

6. For **New DB Snapshot Identifier**, type the name of the DB snapshot copy.
7. (Optional) For **Target Option Group**, choose a new option group.

Specify this option if you are copying a snapshot from one AWS Region to another, and your DB instance uses a nondefault option group.

If your source DB instance uses Transparent Data Encryption for Oracle or Microsoft SQL Server, you must specify this option when copying across Regions. For more information, see [Option group considerations \(p. 356\)](#).

8. (Optional) Select **Copy Tags** to copy tags and values from the snapshot to the copy of the snapshot.
9. (Optional) For **Encryption**, do the following:

- a. Choose **Enable Encryption** if the DB snapshot isn't encrypted but you want to encrypt the copy.

Note

If the DB snapshot is encrypted, you must encrypt the copy, so the check box is already selected.

- b. For **Master key**, specify the AWS KMS key identifier to use to encrypt the DB snapshot copy.

10. Choose **Copy snapshot**.

AWS CLI

You can copy a DB snapshot by using the AWS CLI command `copy-db-snapshot`. If you are copying the snapshot to a new AWS Region, run the command in the new AWS Region.

The following options are used to copy a DB snapshot. Not all options are required for all scenarios. Use the descriptions and the examples that follow to determine which options to use.

- `--source-db-snapshot-identifier` – The identifier for the source DB snapshot.
 - If the source snapshot is in the same AWS Region as the copy, specify a valid DB snapshot identifier. For example, `rds:mysql-instance1-snapshot-20130805`.
 - If the source snapshot is in a different AWS Region than the copy, specify a valid DB snapshot ARN. For example, `arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20130805`.
 - If you are copying from a shared manual DB snapshot, this parameter must be the Amazon Resource Name (ARN) of the shared DB snapshot.
 - If you are copying an encrypted snapshot this parameter must be in the ARN format for the source AWS Region, and must match the `SourceDBSnapshotIdentifier` in the `PreSignedUrl` parameter.
- `--target-db-snapshot-identifier` – The identifier for the new copy of the encrypted DB snapshot.
- `--copy-tags` – Include the `copy tags` option to copy tags and values from the snapshot to the copy of the snapshot.
- `--option-group-name` – The option group to associate with the copy of the snapshot.

Specify this option if you are copying a snapshot from one AWS Region to another, and your DB instance uses a non-default option group.

If your source DB instance uses Transparent Data Encryption for Oracle or Microsoft SQL Server, you must specify this option when copying across Regions. For more information, see [Option group considerations \(p. 356\)](#).

- **--kms-key-id** – The AWS KMS key identifier for an encrypted DB snapshot. The AWS KMS key identifier is the Amazon Resource Name (ARN), key identifier, or key alias for the AWS KMS CMK.
 - If you copy an encrypted DB snapshot from your AWS account, you can specify a value for this parameter to encrypt the copy with a new AWS KMS CMK. If you don't specify a value for this parameter, then the copy of the DB snapshot is encrypted with the same AWS KMS CMK as the source DB snapshot.
 - If you copy an encrypted DB snapshot that is shared from another AWS account, then you must specify a value for this parameter.
 - If you specify this parameter when you copy an unencrypted snapshot, the copy is encrypted.
 - If you copy an encrypted snapshot to a different AWS Region, then you must specify an AWS KMS CMK for the destination AWS Region. AWS KMS CMKs are specific to the AWS Region that they are created in, and you cannot use encryption keys from one AWS Region in another AWS Region.
- **--source-region** – The ID of the AWS Region of the source DB snapshot. If you copy an encrypted snapshot to a different AWS Region, then you must specify this option.

Example from unencrypted, to the same Region

The following code creates a copy of a snapshot, with the new name `mydbsnapshotcopy`, in the same AWS Region as the source snapshot. When the copy is made, all tags on the original snapshot are copied to the snapshot copy.

For Linux, macOS, or Unix:

```
aws rds copy-db-snapshot \  
  --source-db-snapshot-identifier mysql-instance1-snapshot-20130805 \  
  --target-db-snapshot-identifier mydbsnapshotcopy \  
  --copy-tags
```

For Windows:

```
aws rds copy-db-snapshot ^  
  --source-db-snapshot-identifier mysql-instance1-snapshot-20130805 ^  
  --target-db-snapshot-identifier mydbsnapshotcopy ^  
  --copy-tags
```

Example from unencrypted, across Regions

The following code creates a copy of a snapshot, with the new name `mydbsnapshotcopy`, in the AWS Region in which the command is run.

For Linux, macOS, or Unix:

```
aws rds copy-db-snapshot \  
  --source-db-snapshot-identifier arn:aws:rds:us-east-1:123456789012:snapshot:mysql-  
instance1-snapshot-20130805 \  
  --target-db-snapshot-identifier mydbsnapshotcopy
```

For Windows:

```
aws rds copy-db-snapshot ^  
  --source-db-snapshot-identifier arn:aws:rds:us-east-1:123456789012:snapshot:mysql-  
instance1-snapshot-20130805 ^  
  --target-db-snapshot-identifier mydbsnapshotcopy
```

Example from encrypted, across Regions

The following code example copies an encrypted DB snapshot from the US West (Oregon) Region in the US East (N. Virginia) Region. Run the command in the destination (us-east-1) Region.

For Linux, macOS, or Unix:

```
aws rds copy-db-snapshot \
--source-db-snapshot-identifier arn:aws:rds:us-west-2:123456789012:snapshot:mysql-
instance1-snapshot-20161115 \
--target-db-snapshot-identifier mydbsnapshotcopy \
--source-region us-west-2 \
--kms-key-id my-us-east-1-key \
--option-group-name custom-option-group-name
```

For Windows:

```
aws rds copy-db-snapshot ^
--source-db-snapshot-identifier arn:aws:rds:us-west-2:123456789012:snapshot:mysql-
instance1-snapshot-20161115 ^
--target-db-snapshot-identifier mydbsnapshotcopy ^
--source-region us-west-2 ^
--kms-key-id my-us-east-1-key ^
--option-group-name custom-option-group-name
```

RDS API

You can copy a DB snapshot by using the Amazon RDS API operation [CopyDBSnapshot](#). If you are copying the snapshot to a new AWS Region, perform the action in the new AWS Region.

The following parameters are used to copy a DB snapshot. Not all parameters are required for all scenarios. Use the descriptions and the examples that follow to determine which parameters to use.

- **SourceDBSnapshotIdentifier** – The identifier for the source DB snapshot.
 - If the source snapshot is in the same AWS Region as the copy, specify a valid DB snapshot identifier. For example, `rds:mysql-instance1-snapshot-20130805`.
 - If the source snapshot is in a different AWS Region than the copy, specify a valid DB snapshot ARN. For example, `arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20130805`.
 - If you are copying from a shared manual DB snapshot, this parameter must be the Amazon Resource Name (ARN) of the shared DB snapshot.
 - If you are copying an encrypted snapshot this parameter must be in the ARN format for the source AWS Region, and must match the `SourceDBSnapshotIdentifier` in the `PreSignedUrl` parameter.
- **TargetDBSnapshotIdentifier** – The identifier for the new copy of the encrypted DB snapshot.
- **CopyTags** – Set this parameter to `true` to copy tags and values from the snapshot to the copy of the snapshot. The default is `false`.
- **OptionGroupName** – The option group to associate with the copy of the snapshot.

Specify this parameter if you are copying a snapshot from one AWS Region to another, and your DB instance uses a non-default option group.

If your source DB instance uses Transparent Data Encryption for Oracle or Microsoft SQL Server, you must specify this parameter when copying across Regions. For more information, see [Option group considerations \(p. 356\)](#).

- **KmsKeyId** – The AWS KMS key identifier for an encrypted DB snapshot. The AWS KMS key identifier is the Amazon Resource Name (ARN), key identifier, or key alias for the AWS KMS CMK.

- If you copy an encrypted DB snapshot from your AWS account, you can specify a value for this parameter to encrypt the copy with a new AWS KMS CMK. If you don't specify a value for this parameter, then the copy of the DB snapshot is encrypted with the same AWS KMS CMK as the source DB snapshot.
- If you copy an encrypted DB snapshot that is shared from another AWS account, then you must specify a value for this parameter.
- If you specify this parameter when you copy an unencrypted snapshot, the copy is encrypted.
- If you copy an encrypted snapshot to a different AWS Region, then you must specify an AWS KMS CMK for the destination AWS Region. AWS KMS CMKs are specific to the AWS Region that they are created in, and you cannot use encryption keys from one AWS Region in another AWS Region.
- **PreSignedUrl** – The URL that contains a Signature Version 4 signed request for the `CopyDBSnapshot` API operation in the source AWS Region that contains the source DB snapshot to copy.

Specify this parameter when you copy an encrypted DB snapshot from another AWS Region by using the Amazon RDS API. You can specify the source Region option instead of this parameter when you copy an encrypted DB snapshot from another AWS Region by using the AWS CLI.

The presigned URL must be a valid request for the `CopyDBSnapshot` API operation that can be run in the source AWS Region containing the encrypted DB snapshot to be copied. The presigned URL request must contain the following parameter values:

- **DestinationRegion** – The AWS Region that the encrypted DB snapshot will be copied to. This AWS Region is the same one where the `CopyDBSnapshot` operation is called that contains this presigned URL.

For example, suppose that you copy an encrypted DB snapshot from the us-west-2 Region to the us-east-1 Region. You then call the `CopyDBSnapshot` operation in the us-east-1 Region and provide a presigned URL that contains a call to the `CopyDBSnapshot` operation in the us-west-2 Region. For this example, the `DestinationRegion` in the presigned URL must be set to the us-east-1 Region.

- **KmsKeyId** – The AWS KMS key identifier for the key to use to encrypt the copy of the DB snapshot in the destination AWS Region. This is the same identifier for both the `CopyDBSnapshot` operation that is called in the destination AWS Region, and the operation contained in the presigned URL.
- **SourceDBSnapshotIdentifier** – The DB snapshot identifier for the encrypted snapshot to be copied. This identifier must be in the Amazon Resource Name (ARN) format for the source AWS Region. For example, if you are copying an encrypted DB snapshot from the us-west-2 Region, then your `SourceDBSnapshotIdentifier` looks like the following example: `arn:aws:rds:us-west-2:123456789012:snapshot:mysql-instance1-snapshot-20161115`.

For more information on Signature Version 4 signed requests, see the following:

- [Authenticating requests: Using query parameters \(AWS signature version 4\)](#) in the Amazon Simple Storage Service API Reference
- [Signature version 4 signing process](#) in the AWS General Reference

Example from unencrypted, to the same Region

The following code creates a copy of a snapshot, with the new name `mydbsnapshotcopy`, in the same AWS Region as the source snapshot. When the copy is made, all tags on the original snapshot are copied to the snapshot copy.

```
https://rds.us-west-1.amazonaws.com/
?Action=CopyDBSnapshot
&CopyTags=true
&SignatureMethod=HmacSHA256
&SignatureVersion=4
&SourceDBSnapshotIdentifier=mysql-instance1-snapshot-20130805
```

```
&TargetDBSnapshotIdentifier=mydbsnapshotcopy
&Version=2013-09-09
&X-Amz-Algorithm=AWS4-HMAC-SHA256
&X-Amz-Credential=AKIADQKE4SARGYLE/20140429/us-west-1/rds/aws4_request
&X-Amz-Date=20140429T175351Z
&X-Amz-SignedHeaders=content-type;host;user-agent;x-amz-content-sha256;x-amz-date
&X-Amz-Signature=9164337efa99caf850e874a1cb7ef62f3cea29d0b448b9e0e7c53b288ddffed2
```

Example from unencrypted, across Regions

The following code creates a copy of a snapshot, with the new name `mydbsnapshotcopy`, in the US West (N. California) Region.

```
https://rds.us-west-1.amazonaws.com/
?Action=CopyDBSnapshot
&SignatureMethod=HmacSHA256
&SignatureVersion=4

```

Sharing a DB snapshot

Using Amazon RDS, you can share a manual DB snapshot in the following ways:

- Sharing a manual DB snapshot, whether encrypted or unencrypted, enables authorized AWS accounts to copy the snapshot.
- Sharing an unencrypted manual DB snapshot enables authorized AWS accounts to directly restore a DB instance from the snapshot instead of taking a copy of it and restoring from that. However, you can't restore a DB instance from a DB snapshot that is both shared and encrypted. Instead, you can make a copy of the DB snapshot and restore the DB instance from the copy.

Note

To share an automated DB snapshot, create a manual DB snapshot by copying the automated snapshot, and then share that copy. This process also applies to AWS Backup-generated resources.

For more information on copying a snapshot, see [Copying a snapshot \(p. 352\)](#). For more information on restoring a DB instance from a DB snapshot, see [Restoring from a DB snapshot \(p. 349\)](#).

You can share a manual snapshot with up to 20 other AWS accounts. You can also share an unencrypted manual snapshot as public, which makes the snapshot available to all AWS accounts. Take care when sharing a snapshot as public so that none of your private information is included in any of your public snapshots.

You can use the following AWS CLI command (Unix only) to find the public snapshots for your AWS account in a particular AWS Region:

```
aws rds describe-db-snapshots --snapshot-type public --include-public | grep account_number
```

The output returned is similar to the following example if you have public snapshots:

```
"DBSnapshotArn": "arn:aws:rds:us-east-1:123456789012:snapshot:mysnapshot1",
"DBSnapshotArn": "arn:aws:rds:us-east-1:123456789012:snapshot:mysnapshot2",
```

Note

You might see duplicate entries for `DBSnapshotIdentifier` or `SourceDBSnapshotIdentifier`.

The following limitations apply when sharing manual snapshots with other AWS accounts:

- When you restore a DB instance from a shared snapshot using the AWS Command Line Interface (AWS CLI) or Amazon RDS API, you must specify the Amazon Resource Name (ARN) of the shared snapshot as the snapshot identifier.
- You cannot share a DB snapshot that uses an option group with permanent or persistent options, except for Oracle DB instances that have the `Timezone` or `OLS` option (or both).

A *permanent option* cannot be removed from an option group. Option groups with persistent options cannot be removed from a DB instance once the option group has been assigned to the DB instance.

The following table lists permanent and persistent options and their related DB engines.

Option name	Persistent	Permanent	DB engine
TDE	Yes	No	Microsoft SQL Server Enterprise Edition

Option name	Persistent	Permanent	DB engine
TDE	Yes	Yes	Oracle Enterprise Edition
Timezone	Yes	Yes	Oracle Enterprise Edition
			Oracle Standard Edition
			Oracle Standard Edition One
			Oracle Standard Edition Two

For Oracle DB instances, you can copy shared DB snapshots that have the `Timezone` or `OLS` option (or both). To do so, specify a target option group that includes these options when you copy the DB snapshot. The `OLS` option is permanent and persistent only for Oracle DB instances running Oracle version 12.2 or higher. For more information about these options, see [Oracle time zone \(p. 1201\)](#) and [Oracle Label Security \(p. 1167\)](#).

Sharing an encrypted snapshot

You can share DB snapshots that have been encrypted "at rest" using the AES-256 encryption algorithm, as described in [Encrypting Amazon RDS resources \(p. 1630\)](#). To do this, you must take the following steps:

1. Share the AWS Key Management Service (AWS KMS) customer master key (CMK) that was used to encrypt the snapshot with any accounts that you want to be able to access the snapshot.

You can share AWS KMS CMKs with another AWS account by adding the other account to the AWS KMS key policy. For details on updating a key policy, see [Key policies](#) in the *AWS KMS Developer Guide*. For an example of creating a key policy, see [Allowing access to an AWS KMS customer master key \(CMK\) \(p. 366\)](#) later in this topic.

2. Use the AWS Management Console, AWS CLI, or Amazon RDS API to share the encrypted snapshot with the other accounts.

These restrictions apply to sharing encrypted snapshots:

- You can't share encrypted snapshots as public.
- You can't share Oracle or Microsoft SQL Server snapshots that are encrypted using Transparent Data Encryption (TDE).
- You can't share a snapshot that has been encrypted using the default AWS KMS CMK of the AWS account that shared the snapshot.

Allowing access to an AWS KMS customer master key (CMK)

For another AWS account to copy an encrypted DB snapshot shared from your account, the account that you share your snapshot with must have access to the AWS KMS customer master key (CMK) that encrypted the snapshot. To allow another AWS account access to an AWS KMS CMK, update the key policy for the AWS KMS CMK with the ARN of the AWS account that you are sharing to as a `Principal` in the AWS KMS key policy, and then allow the `kms:CreateGrant` action.

After you have given an AWS account access to your AWS KMS CMK, to copy your encrypted snapshot, that AWS account must create an AWS Identity and Access Management (IAM) user if it doesn't already have one. In addition, that AWS account must also attach an IAM policy to that IAM user that allows the IAM user to copy an encrypted DB snapshot using your AWS KMS CMK. The account must be an IAM user and cannot be a root AWS account identity due to AWS KMS security restrictions.

In the following key policy example, user 111122223333 is the owner of the AWS KMS CMK, and user 444455556666 is the account that the key is being shared with. This updated key policy gives the AWS account access to the AWS KMS CMK by including the ARN for the root AWS account identity for user 444455556666 as a Principal for the policy, and by allowing the kms:CreateGrant action.

```
{

            "Effect": "Allow",
            "Principal": {"AWS": [
                "arn:aws:iam::111122223333:user/KeyUser",
                "arn:aws:iam::444455556666:root"
            ]},
            "Action": [
                "kms:CreateGrant",
                "kms:Encrypt",
                "kms:Decrypt",
                "kms:ReEncrypt*",
                "kms:GenerateDataKey*",
                "kms:DescribeKey"
            ],
            "Resource": "*"
        },
        {
            "Sid": "Allow attachment of persistent resources",
            "Effect": "Allow",
            "Principal": {"AWS": [
                "arn:aws:iam::111122223333:user/KeyUser",
                "arn:aws:iam::444455556666:root"
            ]},
            "Action": [
                "kms:CreateGrant",
                "kms>ListGrants",
                "kms:RevokeGrant"
            ],
            "Resource": "*",
            "Condition": {"Bool": {"kms:GrantIsForAWSResource": true}}
        }
    ]
}
```

Creating an IAM policy to enable copying of the encrypted snapshot

Once the external AWS account has access to your AWS KMS customer master key (CMK), the owner of that AWS account can create a policy that allows an IAM user created for that account to copy an encrypted snapshot encrypted with that AWS KMS CMK.

The following example shows a policy that can be attached to an IAM user for AWS account 444455556666 that enables the IAM user to copy a shared snapshot from AWS account 111122223333 that has been encrypted with the AWS KMS CMK c989c1dd-a3f2-4a5d-8d96-e793d082ab26 in the us-west-2 region.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "AllowUseOfTheKey",
            "Effect": "Allow",
            "Action": [
                "kms:CopyGrant"
            ],
            "Resource": [
                "arn:aws:kms:us-west-2:111122223333:key/c989c1dd-a3f2-4a5d-8d96-e793d082ab26"
            ]
        }
    ]
}
```

```
"Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:ReEncrypt*",
    "kms:GenerateDataKey*",
    "kms:DescribeKey",
    "kms:CreateGrant",
    "kms:RetireGrant"
],
"Resource": ["arn:aws:kms:us-west-2:111122223333:key/c989c1dd-a3f2-4a5d-8d96-
e793d082ab26"]
},
{
    "Sid": "AllowAttachmentOfPersistentResources",
    "Effect": "Allow",
    "Action": [
        "kms:CreateGrant",
        "kms>ListGrants",
        "kms:RevokeGrant"
    ],
    "Resource": ["arn:aws:kms:us-west-2:111122223333:key/c989c1dd-a3f2-4a5d-8d96-
e793d082ab26"],
    "Condition": {
        "Bool": {
            "kms:GrantIsForAWSResource": true
        }
    }
}
]
```

For details on updating a key policy, see [Key policies in the AWS KMS Developer Guide](#).

Sharing a snapshot

You can share a DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

Console

Using the Amazon RDS console, you can share a manual DB snapshot with up to 20 AWS accounts. You can also use the console to stop sharing a manual snapshot with one or more accounts.

To share a manual DB snapshot by using the Amazon RDS console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Select the manual snapshot that you want to share.
4. For **Actions**, choose **Share Snapshot**.
5. Choose one of the following options for **DB snapshot visibility**.
 - If the source is unencrypted, choose **Public** to permit all AWS accounts to restore a DB instance from your manual DB snapshot, or choose **Private** to permit only AWS accounts that you specify to restore a DB instance from your manual DB snapshot.

Warning

If you set **DB snapshot visibility** to **Public**, all AWS accounts can restore a DB instance from your manual DB snapshot and have access to your data. Do not share any manual DB snapshots that contain private information as **Public**.

- If the source is encrypted, **DB snapshot visibility** is set as **Private** because encrypted snapshots can't be shared as public.
6. For **AWS Account ID**, type the AWS account identifier for an account that you want to permit to restore a DB instance from your manual snapshot, and then choose **Add**. Repeat to include additional AWS account identifiers, up to 20 AWS accounts.

If you make an error when adding an AWS account identifier to the list of permitted accounts, you can delete it from the list by choosing **Delete** at the right of the incorrect AWS account identifier.

Snapshot permissions

Preferences

You are sharing an unencrypted DB snapshot. When you share an unencrypted DB snapshot, you give the other account permission to make a copy of the DB snapshot and to restore a database from your DB snapshot.

DB snapshot

AWS account ID

AWS account ID	<input type="button" value="Delete"/>
Please add AWS account ID	

7. After you have added identifiers for all of the AWS accounts that you want to permit to restore the manual snapshot, choose **Save** to save your changes.

To stop sharing a manual DB snapshot with an AWS account

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Select the manual snapshot that you want to stop sharing.
4. Choose **Actions**, and then choose **Share Snapshot**.
5. To remove permission for an AWS account, choose **Delete** for the AWS account identifier for that account from the list of authorized accounts.

Snapshot permissions

Preferences

You are sharing an unencrypted DB snapshot. When you share an unencrypted DB snapshot, you give the other account permission to make a copy of the DB snapshot and to restore a database from your DB snapshot.

AWS CLI

To share a DB snapshot, use the `aws rds modify-db-snapshot-attribute` command. Use the `--values-to-add` parameter to add a list of the IDs for the AWS accounts that are authorized to restore the manual snapshot.

Example of sharing a snapshot with a single account

The following example enables AWS account identifier 123456789012 to restore the DB snapshot named db7-snapshot.

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot-attribute \
--db-snapshot-identifier db7-snapshot \
--attribute-name restore \
--values-to-add 123456789012
```

For Windows:

```
aws rds modify-db-snapshot-attribute ^
--db-snapshot-identifier db7-snapshot ^
--attribute-name restore ^
--values-to-add 123456789012
```

Example of sharing a snapshot with multiple accounts

The following example enables two AWS account identifiers, 111122223333 and 444455556666, to restore the DB snapshot named manual-snapshot1.

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot-attribute \
--db-snapshot-identifier manual-snapshot1 \
--attribute-name restore \
--values-to-add {"111122223333","444455556666"}
```

For Windows:

```
aws rds modify-db-snapshot-attribute ^
--db-snapshot-identifier manual-snapshot1 ^
--attribute-name restore ^
--values-to-add "[\"111122223333\", \"444455556666\"]"
```

Note

When using the Windows command prompt, you must escape double quotes ("") in JSON code by prefixing them with a backslash (\).

To remove an AWS account identifier from the list, use the --values-to-remove parameter.

Example of stopping snapshot sharing

The following example prevents AWS account ID 444455556666 from restoring the snapshot.

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot-attribute \
--db-snapshot-identifier manual-snapshot1 \
--attribute-name restore \
--values-to-remove 444455556666
```

For Windows:

```
aws rds modify-db-snapshot-attribute ^
--db-snapshot-identifier manual-snapshot1 ^
--attribute-name restore ^
--values-to-remove 444455556666
```

To list the AWS accounts enabled to restore a snapshot, use the [describe-db-snapshot-attributes](#) AWS CLI command.

RDS API

You can also share a manual DB snapshot with other AWS accounts by using the Amazon RDS API. To do so, call the [ModifyDBSnapshotAttribute](#) operation. Specify `restore` for `AttributeName`, and use the `ValuesToAdd` parameter to add a list of the IDs for the AWS accounts that are authorized to restore the manual snapshot.

To make a manual snapshot public and restorable by all AWS accounts, use the value `all`. However, take care not to add the `all` value for any manual snapshots that contain private information that you don't want to be available to all AWS accounts. Also, don't specify `all` for encrypted snapshots, because making such snapshots public isn't supported.

To remove sharing permission for an AWS account, use the [ModifyDBSnapshotAttribute](#) operation with `AttributeName` set to `restore` and the `ValuesToRemove` parameter. To mark a manual snapshot as private, remove the value `all` from the values list for the `restore` attribute.

To list all of the AWS accounts permitted to restore a snapshot, use the [DescribeDBSnapshotAttributes](#) API operation.

Exporting DB snapshot data to Amazon S3

You can export DB snapshot data to an Amazon S3 bucket. After the data is exported, you can analyze the exported data directly through tools like Amazon Athena or Amazon Redshift Spectrum. The export process runs in the background and doesn't affect the performance of your active DB instance.

When you export a DB snapshot, Amazon RDS extracts data from the snapshot and stores it in an Amazon S3 bucket in your account. The data is stored in an Apache Parquet format that is compressed and consistent.

You can export all types of DB snapshots—including manual snapshots, automated system snapshots, and snapshots created by the AWS Backup service. By default, all data in the snapshot is exported. However, you can choose to export specific sets of databases, schemas, or tables.

Amazon RDS supports exporting snapshots in all AWS Regions except the following:

- AWS GovCloud (US-East)
- AWS GovCloud (US-West)

The following table shows the engine versions that are supported for exporting snapshot data to Amazon S3.

MariaDB	MySQL	PostgreSQL
10.3	8.0.13 and higher	11.2 and higher
10.2.12 and higher	5.7.24 and higher	10.7 and higher
10.1.26 and higher	5.6.40 and higher	9.6.6–9.6.9, 9.6.12 and higher
10.0.32 and higher		

For complete lists of engine versions supported by Amazon RDS, see the following:

- [MariaDB on Amazon RDS versions \(p. 576\)](#)
- [MySQL on Amazon RDS versions \(p. 828\)](#)
- [Supported PostgreSQL database versions \(p. 1461\)](#)

Topics

- [Limitations \(p. 374\)](#)
- [Overview of exporting snapshot data \(p. 374\)](#)
- [Setting up access to an Amazon S3 bucket \(p. 374\)](#)
- [Exporting a snapshot to an Amazon S3 bucket \(p. 377\)](#)
- [Monitoring snapshot exports \(p. 379\)](#)
- [Canceling a snapshot export task \(p. 380\)](#)
- [Troubleshooting PostgreSQL permissions errors \(p. 381\)](#)
- [File naming convention \(p. 382\)](#)
- [Data conversion when exporting to an Amazon S3 bucket \(p. 382\)](#)

Limitations

Exporting DB snapshot data to S3 has the following limitations:

- Exporting snapshots from DB instances that use magnetic storage isn't supported.
- If a database, schema, or table has characters in its name other than the following, partial export isn't supported. However, you can export the entire DB snapshot.
 - Latin letters (A–Z)
 - Digits (0–9)
 - Dollar symbol (\$)
 - Underscore (_)
- Some characters aren't supported in database table column names. Tables with the following characters in column names are skipped during export:

```
, ; { } ( ) \n \t =
```

- If the data contains a huge value close to or greater than 500 MB, the export fails.

Overview of exporting snapshot data

You use the following process to export DB snapshot data to an Amazon S3 bucket. For more details, see the following sections.

1. Identify the snapshot to export.

Use an existing automated or manual snapshot, or create a manual snapshot of a DB instance.

2. Set up access to the Amazon S3 bucket.

A *bucket* is a container for Amazon S3 objects or files. To provide the information to access a bucket, take the following steps:

- a. Identify the S3 bucket where the snapshot is to be exported to. The S3 bucket must be in the same AWS Region as the snapshot. For more information, see [Identifying the Amazon S3 bucket for export \(p. 375\)](#).
 - b. Create an AWS Key Management Service (AWS KMS) customer master key (CMK) for the server-side encryption. The AWS KMS CMK is used by the snapshot export task to set up AWS KMS server-side encryption when writing the export data to S3. For more information, see [Encrypting Amazon RDS resources \(p. 1630\)](#).
 - c. Create an AWS Identity and Access Management (IAM) role that grants the snapshot export task access to the S3 bucket. For more information, see [Providing access to an Amazon S3 bucket using an IAM role \(p. 375\)](#).
3. Export the snapshot to Amazon S3 using the console or the `start-export-task` CLI command. For more information, see [Exporting a snapshot to an Amazon S3 bucket \(p. 377\)](#).
 4. To access your exported data in the Amazon S3 bucket, see [Uploading, downloading, and managing objects in the Amazon Simple Storage Service Console User Guide](#).

Setting up access to an Amazon S3 bucket

To export DB snapshot data to an Amazon S3 file, you first give the snapshot permission to access the Amazon S3 bucket. You then create an IAM role to allow the Amazon RDS service to write to the Amazon S3 bucket.

Topics

- [Identifying the Amazon S3 bucket for export \(p. 375\)](#)
- [Providing access to an Amazon S3 bucket using an IAM role \(p. 375\)](#)

Identifying the Amazon S3 bucket for export

Identify the Amazon S3 bucket to export the DB snapshot to. Use an existing S3 bucket or create a new S3 bucket.

Note

The S3 bucket to export to must be in the same AWS Region as the snapshot.

For more information about working with Amazon S3 buckets, see the following in the *Amazon Simple Storage Service Console User Guide*:

- [How do I view the properties for an S3 bucket?](#)
- [How do I enable default encryption for an Amazon S3 bucket?](#)
- [How do I create an S3 bucket?](#)

Providing access to an Amazon S3 bucket using an IAM role

Before you export DB snapshot data to Amazon S3, give the snapshot export tasks write-access permission to the Amazon S3 bucket.

To do this, create an IAM policy that provides access to the bucket. Then create an IAM role and attach the policy to the role. You later assign the IAM role to your snapshot export task.

Important

If you plan to use the AWS Management Console to export your snapshot, you can choose to create the IAM policy and the role automatically when you export the snapshot. For instructions, see [Exporting a snapshot to an Amazon S3 bucket \(p. 377\)](#).

To give DB snapshot tasks access to Amazon S3

1. Create an IAM policy. This policy provides the bucket and object permissions that allow your snapshot export task to access Amazon S3.

Include in the policy the following required actions to allow the transfer of files from Amazon RDS to an S3 bucket:

- `s3:PutObject*`
- `s3:GetObject*`
- `s3>ListBucket`
- `s3>DeleteObject*`
- `s3:GetBucketLocation`

Include in the policy the following resources to identify the S3 bucket and objects in the bucket. The following list of resources shows the Amazon Resource Name (ARN) format for accessing Amazon S3.

- `arn:aws:s3:::your-s3-bucket`
- `arn:aws:s3:::your-s3-bucket/*`

For more information on creating an IAM policy for Amazon RDS, see [Creating and using an IAM policy for IAM database access \(p. 1664\)](#). See also [Tutorial: Create and attach your first customer managed policy](#) in the *IAM User Guide*.

The following AWS CLI command creates an IAM policy named `ExportPolicy` with these options. It grants access to a bucket named `your-s3-bucket`.

Note

After you create the policy, note the ARN of the policy. You need the ARN for a subsequent step when you attach the policy to an IAM role.

```
aws iam create-policy --policy-name ExportPolicy --policy-document '{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3>ListBucket",  
                "s3:GetBucketLocation"  
            ],  
            "Resource": [  
                "arn:aws:s3:::*"  
            ]  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3:PutObject*",  
                "s3:GetObject*",  
                "s3:CopyObject*",  
                "s3>DeleteObject*"  
            ],  
            "Resource": [  
                "arn:aws:s3:::your-s3-bucket",  
                "arn:aws:s3:::your-s3-bucket/*"  
            ]  
        }  
    ]  
}'
```

2. Create an IAM role. You do this so that Amazon RDS can assume this IAM role on your behalf to access your Amazon S3 buckets. For more information, see [Creating a role to delegate permissions to an IAM user](#) in the *IAM User Guide*.

The following example shows using the AWS CLI command to create a role named `rds-s3-export-role`.

```
aws iam create-role --role-name rds-s3-export-role --assume-role-policy-document '{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Principal": {  
                "Service": "export.rds.amazonaws.com"  
            },  
            "Action": "sts:AssumeRole"  
        }  
    ]  
}'
```

3. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy created earlier to the role named `rds-s3-export-role`. Replace `your-policy-arn` with the policy ARN that you noted in an earlier step.

```
aws iam attach-role-policy --policy-arn your-policy-arn --role-name rds-s3-export-role
```

Exporting a snapshot to an Amazon S3 bucket

You can have up to five concurrent DB snapshot export tasks in progress per account.

Note

Exporting RDS snapshots can take a while depending on your database type and size. The export task first restores and scales the entire database before extracting the data to Amazon S3. The task's progress during this phase displays as **Starting**. When the task switches to exporting data to S3, progress displays as **In progress**.

The time it takes for the export to complete depends on the data stored in the database. For example, tables with well distributed numeric primary key or index columns will export the fastest. Tables that don't contain a column suitable for partitioning and tables with only one index on a string-based column will take longer because the export uses a slower single threaded process.

You can export a DB snapshot to Amazon S3 using the AWS Management Console, the AWS CLI, or the RDS API.

If you use a Lambda function to export a snapshot, add the `kms:DescribeKey` action to the Lambda function policy. For more information, see [AWS Lambda permissions](#).

Console

The **Export to Amazon S3** console option appears only for snapshots that can be exported to Amazon S3. A snapshot might not be available for export because of the following reasons:

- The DB engine isn't supported for S3 export.
- The DB instance version isn't supported for S3 export.
- S3 export isn't supported in the AWS Region where the snapshot was created.

To export a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. From the tabs, choose the type of snapshot that you want to export.
4. In the list of snapshots, choose the snapshot that you want to export.
5. For **Actions**, choose **Export to Amazon S3**.

The **Export to Amazon S3** window appears.

6. For **Export identifier**, enter a name to identify the export task. This value is also used for the name of the file created in the S3 bucket.
7. Choose the amount of data to be exported:
 - Choose **All** to export all data in the snapshot.
 - Choose **Partial** to export specific parts of the snapshot. To identify which parts of the snapshot to export, enter one or more tables for **Identifiers**.

8. For **S3 bucket**, choose the bucket to export to.

To assign the exported data to a folder path in the S3 bucket, enter the optional path for **S3 prefix**.

9. For **IAM role**, either choose a role that grants you write access to your chosen S3 bucket, or create a new role.
 - If you created a role by following the steps in [Providing access to an Amazon S3 bucket using an IAM role \(p. 375\)](#), choose that role.
 - If you didn't create a role that grants you write access to your chosen S3 bucket, choose **Create a new role** to create the role automatically. Next, enter a name for the role in **IAM role name**.
10. For **Master key**, enter the ARN for the key to use for encrypting the exported data.
11. Choose **Export to Amazon S3**.

AWS CLI

To export a DB snapshot to Amazon S3 using the AWS CLI, use the [start-export-task](#) command with the following required options:

- `--export-task-identifier`
- `--source-arn`
- `--s3-bucket-name`
- `--iam-role-arn`
- `--kms-key-id`

In the following examples, the snapshot export task is named `my_snapshot_export`, which exports a snapshot to an S3 bucket named `my_export_bucket`.

Example

For Linux, macOS, or Unix:

```
aws rds start-export-task \
--export-task-identifier my_snapshot_export \
--source-arn arn:aws:rds:AWS_Region:123456789012:snapshot:snapshot_name \
--s3-bucket-name my_export_bucket \
--iam-role-arn iam_role \
--kms-key-id master_key
```

For Windows:

```
aws rds start-export-task ^
--export-task-identifier my_snapshot_export ^
--source-arn arn:aws:rds:AWS_Region:123456789012:snapshot:snapshot_name ^
--s3-bucket-name my_export_bucket ^
--iam-role-arn iam_role ^
--kms-key-id master_key
```

Sample output follows.

```
{  
    "Status": "STARTING",  
    "IamRoleArn": "iam_role",  
    "ExportTime": "2019-08-12T01:23:53.109Z",  
    "S3Bucket": "my_export_bucket",  
    "PercentProgress": 0,  
    "KmsKeyId": "master_key",  
}
```

```
    "ExportTaskIdentifier": "my_snapshot_export",
    "TotalExtractedDataInGB": 0,
    "TaskStartTime": "2019-11-13T19:46:00.173Z",
    "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:snapshot_name"
}
```

To provide a folder path in the S3 bucket for the snapshot export, include the `--s3-prefix` option in the [start-export-task](#) command.

RDS API

To export a DB snapshot to Amazon S3 using the Amazon RDS API, use the [StartExportTask](#) operation with the following required parameters:

- `ExportTaskIdentifier`
- `SourceArn`
- `S3BucketName`
- `IamRoleArn`
- `KmsKeyId`

Monitoring snapshot exports

You can monitor DB snapshot exports using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To monitor DB snapshot exports

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. To view the list of snapshot exports, choose the **Exports in Amazon S3** tab.
4. To view information about a specific snapshot export, choose the export task.

AWS CLI

To monitor DB snapshot exports using the AWS CLI, use the [describe-export-tasks](#) command.

The following example shows how to display current information about all of your snapshot exports.

Example

```
aws rds describe-export-tasks

{
    "ExportTasks": [
        {
            "Status": "CANCELED",
            "TaskEndTime": "2019-11-01T17:36:46.961Z",
            "S3Prefix": "something",
            "ExportTime": "2019-10-24T20:23:48.364Z",
            "S3Bucket": "examplebucket",
            "PercentProgress": 0,
            "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/K7MDENG/bPxRfiCYEXAMPLEKEY",
            "ExportTaskIdentifier": "anewtest",
```

```

    "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
    "TotalExtractedDataInGB": 0,
    "TaskStartTime": "2019-10-25T19:10:58.885Z",
    "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:parameter-groups-
test"
},
{
    "Status": "COMPLETE",
    "TaskEndTime": "2019-10-31T21:37:28.312Z",

    "ExportTaskIdentifier": "thursday-events-test",
    "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
    "TotalExtractedDataInGB": 263,
    "TaskStartTime": "2019-10-31T20:58:06.998Z",
    "SourceArn":
"arn:aws:rds:AWS_Region:123456789012:snapshot:rds:example-1-2019-10-31-06-44"
},
{
    "Status": "FAILED",
    "TaskEndTime": "2019-10-31T02:12:36.409Z",
    "FailureCause": "The S3 bucket edgcuc-export isn't located in the current AWS
Region. Please, review your S3 bucket name and retry the export.",
    "S3Prefix": "",
    "ExportTime": "2019-10-30T06:45:04.526Z",
    "S3Bucket": "examplebucket2",
    "PercentProgress": 0,
    "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/2Zp9Utk/
h3yCo8nzbEXAMPLEKEY",
    "ExportTaskIdentifier": "wednesday-afternoon-test",
    "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
    "TotalExtractedDataInGB": 0,
    "TaskStartTime": "2019-10-30T22:43:40.034Z",
    "SourceArn":
"arn:aws:rds:AWS_Region:123456789012:snapshot:rds:example-1-2019-10-30-06-45"
}
]
}

```

To display information about a specific snapshot export, include the `--export-task-identifier` option with the `describe-export-tasks` command. To filter the output, include the `--Filters` option. For more options, see the [describe-export-tasks](#) command.

RDS API

To display information about DB snapshot exports using the Amazon RDS API, use the [DescribeExportTasks](#) operation.

To track completion of the export workflow or to trigger another workflow, you can subscribe to Amazon Simple Notification Service topics. For more information on Amazon SNS, see [Using Amazon RDS event notification \(p. 487\)](#).

Canceling a snapshot export task

You can cancel a DB snapshot export task using the AWS Management Console, the AWS CLI, or the RDS API.

Note

Cancelling a snapshot export task doesn't remove any data that was exported to Amazon S3. For information about how to delete the data using the console, see [How do I delete objects from an S3 bucket?](#) To delete the data using the CLI, use the `delete-object` command.

Console

To cancel a snapshot export task

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the **Exports in Amazon S3** tab.
4. Choose the snapshot export task that you want to cancel.
5. Choose **Cancel**.
6. Choose **Cancel export task** on the confirmation page.

AWS CLI

To cancel a snapshot export task using the AWS CLI, use the `cancel-export-task` command. The command requires the `--export-task-identifier` option.

Example

```
aws rds cancel-export-task --export-task-identifier my_export
{
    "Status": "CANCELING",
    "S3Prefix": "",
    "ExportTime": "2019-08-12T01:23:53.109Z",
    "S3Bucket": "examplebucket",
    "PercentProgress": 0,
    "KmsKeyId": "arn:aws:kms:AWS_Region:123456789012:key/K7MDENG/bPxRfiCYEXAMPLEKEY",
    "ExportTaskIdentifier": "my_export",
    "IamRoleArn": "arn:aws:iam::123456789012:role/export-to-s3",
    "TotalExtractedDataInGB": 0,
    "TaskStartTime": "2019-11-13T19:46:00.173Z",
    "SourceArn": "arn:aws:rds:AWS_Region:123456789012:snapshot:export-example-1"
}
```

RDS API

To cancel a snapshot export task using the Amazon RDS API, use the `CancelExportTask` operation with the `ExportTaskIdentifier` parameter.

Troubleshooting PostgreSQL permissions errors

When exporting PostgreSQL databases to Amazon S3, you might see a `PERMISSIONS_DO_NOT_EXIST` error stating that certain tables were skipped. This is usually caused by the superuser, which you specify when creating the DB instance, not having permissions to access those tables.

To fix this error, run the following command:

```
GRANT ALL PRIVILEGES ON ALL TABLES IN SCHEMA schema_name TO superuser_name
```

For more information on superuser privileges, see [Master user account privileges \(p. 1712\)](#).

File naming convention

Exported data for specific tables is stored in the format `base_prefix/files`, where the base prefix is the following:

```
export_identifier/database_name/schema_name.table_name/
```

For example:

```
export-1234567890123-459/rdststdb/rdststdb.DataInsert_7ADB5D19965123A2/
```

There are two conventions for how files are named:

- `part-partition_index-random_uuid.format-based_extension`
- `partition_index/part-00000-random_uuid.format-based_extension`

For example:

```
part-00000-c5a881bb-58ff-4ee6-1111-b41ecff340a3-c000.gz.parquet
part-00001-d7a881cc-88cc-5ab7-2222-c41ecab340a4-c000.gz.parquet
part-00002-f5a991ab-59aa-7fa6-3333-d41eccd340a7-c000.gz.parquet
```

```
1/part-00000-c5a881bb-58ff-4ee6-1111-b41ecff340a3-c000.gz.parquet
2/part-00000-d7a881cc-88cc-5ab7-2222-c41ecab340a4-c000.gz.parquet
3/part-00000-f5a991ab-59aa-7fa6-3333-d41eccd340a7-c000.gz.parquet
```

The file naming convention is subject to change. Therefore, when reading target tables we recommend that you read everything inside the base prefix for the table.

Data conversion when exporting to an Amazon S3 bucket

When you export a DB snapshot to an Amazon S3 bucket, Amazon RDS converts data to, exports data in, and stores data in the Parquet format. For more information about Parquet, see the [Apache Parquet](#) website.

Parquet stores all data as one of the following primitive types:

- BOOLEAN
- INT32
- INT64
- INT96
- FLOAT
- DOUBLE
- BYTE_ARRAY – A variable-length byte array, also known as binary
- FIXED_LEN_BYTE_ARRAY – A fixed-length byte array used when the values have a constant size

The Parquet data types are few to reduce the complexity of reading and writing the format. Parquet provides logical types for extending primitive types. A *logical type* is implemented as an annotation with the data in a `LogicalType` metadata field. The logical type annotation explains how to interpret the primitive type.

When the `STRING` logical type annotates a `BYTE_ARRAY` type, it indicates that the byte array should be interpreted as a UTF-8 encoded character string. After an export task completes, Amazon RDS notifies you if any string conversion occurred. The underlying data exported is always the same as the data from the source. However, due to the encoding difference in UTF-8, some characters might appear different from the source when read in tools such as Athena.

For more information, see [Parquet logical type definitions](#) in the Parquet documentation.

MySQL and MariaDB data type mapping to Parquet

The following table shows the mapping from MySQL and MariaDB data types to Parquet data types when data is converted and exported to Amazon S3.

Source data type	Parquet primitive type	Logical type annotation	Conversion notes
Numeric data types			
BIGINT	INT64		
BIGINT UNSIGNED	FIXED_LEN_BYTE_ARRAY(9)DECIMAL(20,0)		Parquet supports only signed types, so the mapping requires an additional byte (8 plus 1) to store the BIGINT_UNSIGNED type.
BIT	BYTE_ARRAY		
DECIMAL	INT32	DECIMAL(p,s)	If the source value is less than 2^{31} , it's stored as INT32.
	INT64	DECIMAL(p,s)	If the source value is 2^{31} or greater, but less than 2^{63} , it's stored as INT64.
	FIXED_LEN_BYTE_ARRAY(ND)DECIMAL(p,s)		If the source value is 2^{63} or greater, it's stored as FIXED_LEN_BYTE_ARRAY(N).
	BYTE_ARRAY	STRING	Parquet doesn't support Decimal precision greater than 38. The Decimal value is converted to a string in a BYTE_ARRAY type and encoded as UTF8.
DOUBLE	DOUBLE		
FLOAT	DOUBLE		

Source data type	Parquet primitive type	Logical type annotation	Conversion notes
INT	INT32		
INT UNSIGNED	INT64		
MEDIUMINT	INT32		
MEDIUMINT UNSIGNED	INT64		
NUMERIC	INT32	DECIMAL(p,s)	If the source value is less than 2^{31} , it's stored as INT32.
	INT64	DECIMAL(p,s)	If the source value is 2^{31} or greater, but less than 2^{63} , it's stored as INT64.
	FIXED_LEN_ARRAY(N)	DECIMAL(p,s)	If the source value is 2^{63} or greater, it's stored as FIXED_LEN_BYTE_ARRAY(N).
	BYTE_ARRAY	STRING	Parquet doesn't support Numeric precision greater than 38. This Numeric value is converted to a string in a BYTE_ARRAY type and encoded as UTF8.
SMALLINT	INT32		
SMALLINT UNSIGNED	INT32		
TINYINT	INT32		
TINYINT UNSIGNED	INT32		
String data types			
BINARY	BYTE_ARRAY		
BLOB	BYTE_ARRAY		
CHAR	BYTE_ARRAY		
ENUM	BYTE_ARRAY	STRING	
LINESTRING	BYTE_ARRAY		
LONGBLOB	BYTE_ARRAY		
LONGTEXT	BYTE_ARRAY	STRING	
MEDIUMBLOB	BYTE_ARRAY		
MEDIUMTEXT	BYTE_ARRAY	STRING	
MULTILINESTRING	BYTE_ARRAY		
SET	BYTE_ARRAY	STRING	

Source data type	Parquet primitive type	Logical type annotation	Conversion notes
TEXT	BYTE_ARRAY	STRING	
TINYBLOB	BYTE_ARRAY		
TINYTEXT	BYTE_ARRAY	STRING	
VARBINARY	BYTE_ARRAY		
VARCHAR	BYTE_ARRAY	STRING	
Date and time data types			
DATE	BYTE_ARRAY	STRING	A date is converted to a string in a BYTE_ARRAY type and encoded as UTF8.
DATETIME	INT64	TIMESTAMP_MICROS	
TIME	BYTE_ARRAY	STRING	A TIME type is converted to a string in a BYTE_ARRAY and encoded as UTF8.
TIMESTAMP	INT64	TIMESTAMP_MICROS	
YEAR	INT32		
Geometric data types			
GEOMETRY	BYTE_ARRAY		
GEOMETRYCOLLECTION	BYTE_ARRAY		
MULTIPOINT	BYTE_ARRAY		
MULTIPOLYGON	BYTE_ARRAY		
POINT	BYTE_ARRAY		
POLYGON	BYTE_ARRAY		
JSON data type			
JSON	BYTE_ARRAY	STRING	

PostgreSQL data type mapping to Parquet

The following table shows the mapping from PostgreSQL data types to Parquet data types when data is converted and exported to Amazon S3.

PostgreSQL data type	Parquet primitive type	Logical type annotation	Mapping notes
Numeric data types			

PostgreSQL data type	Parquet primitive type	Logical type annotation	Mapping notes
BIGINT	INT64		
BIGSERIAL	INT64		
DECIMAL	BYTE_ARRAY	STRING	A DECIMAL type is converted to a string in a BYTE_ARRAY type and encoded as UTF8. This conversion is to avoid complications due to data precision and data values that are not a number (NaN).
DOUBLE PRECISION	DOUBLE		
INTEGER	INT32		
MONEY	BYTE_ARRAY	STRING	
REAL	FLOAT		
SERIAL	INT32		
SMALLINT	INT32	INT_16	
SMALLSERIAL	INT32	INT_16	
String and related data types			
ARRAY	BYTE_ARRAY	STRING	An array is converted to a string and encoded as BINARY (UTF8). This conversion is to avoid complications due to data precision, data values that are not a number (NaN), and time data values.
BIT	BYTE_ARRAY	STRING	
BIT VARYING	BYTE_ARRAY	STRING	
BYTEA	BINARY		
CHAR	BYTE_ARRAY	STRING	
CHAR(N)	BYTE_ARRAY	STRING	
ENUM	BYTE_ARRAY	STRING	
NAME	BYTE_ARRAY	STRING	
TEXT	BYTE_ARRAY	STRING	

PostgreSQL data type	Parquet primitive type	Logical type annotation	Mapping notes
TEXT SEARCH	BYTE_ARRAY	STRING	
VARCHAR(N)	BYTE_ARRAY	STRING	
XML	BYTE_ARRAY	STRING	
Date and time data types			
DATE	BYTE_ARRAY	STRING	
INTERVAL	BYTE_ARRAY	STRING	
TIME	BYTE_ARRAY	STRING	
TIME WITH TIME ZONE	BYTE_ARRAY	STRING	
TIMESTAMP	BYTE_ARRAY	STRING	
TIMESTAMP WITH TIME ZONE	BYTE_ARRAY	STRING	
Geometric data types			
BOX	BYTE_ARRAY	STRING	
CIRCLE	BYTE_ARRAY	STRING	
LINE	BYTE_ARRAY	STRING	
LINESEGMENT	BYTE_ARRAY	STRING	
PATH	BYTE_ARRAY	STRING	
POINT	BYTE_ARRAY	STRING	
POLYGON	BYTE_ARRAY	STRING	
JSON data types			
JSON	BYTE_ARRAY	STRING	
JSONB	BYTE_ARRAY	STRING	
Other data types			
BOOLEAN	BOOLEAN		
CIDR	BYTE_ARRAY	STRING	Network data type
COMPOSITE	BYTE_ARRAY	STRING	
DOMAIN	BYTE_ARRAY	STRING	
INET	BYTE_ARRAY	STRING	Network data type
MACADDR	BYTE_ARRAY	STRING	
OBJECT IDENTIFIER	N/A		
PG_LSN	BYTE_ARRAY	STRING	

PostgreSQL data type	Parquet primitive type	Logical type annotation	Mapping notes
RANGE	BYTE_ARRAY	STRING	
UUID	BYTE_ARRAY	STRING	

Restoring a DB instance to a specified time

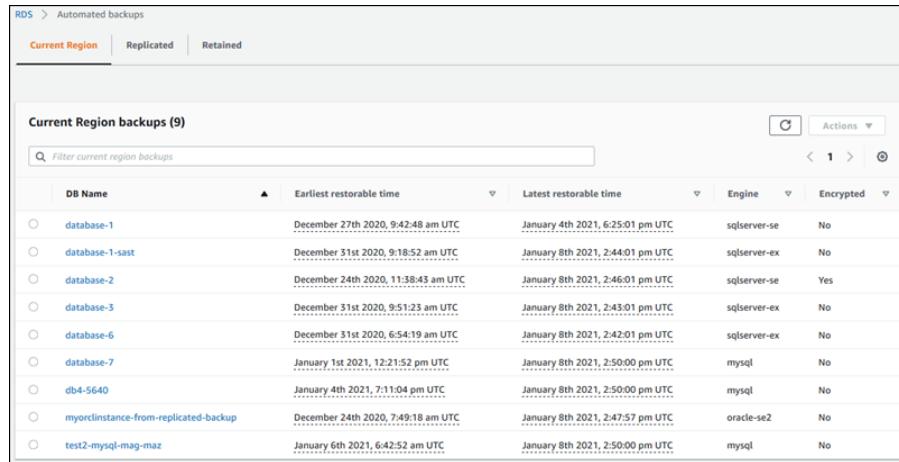

You can restore a DB instance to a specific point in time, creating a new DB instance.

When you restore a DB instance to a point in time, the default DB security group is applied to the new DB instance. If you need custom DB security groups applied to your DB instance, you must apply them explicitly using the AWS Management Console, the AWS CLI `modify-db-instance` command, or the Amazon RDS API `ModifyDBInstance` operation after the DB instance is available.

Restored DB instances are automatically associated with the default parameter and option groups. However, you can apply a custom parameter group and option group by specifying them during a restore.

RDS uploads transaction logs for DB instances to Amazon S3 every 5 minutes. To see the latest restorable time for a DB instance, use the AWS CLI `describe-db-instances` command and look at the value returned in the `LatestRestorableTime` field for the DB instance. To see the latest restorable time for each DB instance in the Amazon RDS console, choose **Automated backups**.

You can restore to any point in time within your backup retention period. To see the earliest restorable time for each DB instance, choose **Automated backups** in the Amazon RDS console.

DB Name	Earliest restorable time	Latest restorable time	Engine	Encrypted
database-1	December 27th 2020, 9:42:48 am UTC	January 4th 2021, 6:25:01 pm UTC	sqlserver-se	No
database-1-sast	December 31st 2020, 9:18:52 am UTC	January 8th 2021, 2:44:01 pm UTC	sqlserver-ex	No
database-2	December 24th 2020, 11:38:43 am UTC	January 8th 2021, 2:46:01 pm UTC	sqlserver-se	Yes
database-3	December 31st 2020, 9:51:23 am UTC	January 8th 2021, 2:43:01 pm UTC	sqlserver-ex	No
database-6	December 31st 2020, 6:54:19 am UTC	January 8th 2021, 2:42:01 pm UTC	sqlserver-ex	No
database-7	January 1st 2021, 12:21:52 pm UTC	January 8th 2021, 2:50:00 pm UTC	mysql	No
db4-5640	January 4th 2021, 7:11:04 pm UTC	January 8th 2021, 2:50:00 pm UTC	mysql	No
myordinstance-from-replicated-backup	December 24th 2020, 7:49:18 am UTC	January 8th 2021, 2:47:57 pm UTC	oracle-se2	No
test2-mysql-mag-maz	January 6th 2021, 6:42:52 am UTC	January 8th 2021, 2:50:00 pm UTC	mysql	No

Note

We recommend that you restore to the same or similar DB instance size—and IOPS if using Provisioned IOPS storage—as the source DB instance. You might get an error if, for example, you choose a DB instance size with an incompatible IOPS value.

Some of the database engines used by Amazon RDS have special considerations when restoring from a point in time:

- When you restore an Oracle DB instance to a point in time, you can specify a different Oracle DB engine, license model, and DBName (SID) to be used by the new DB instance.
- When you restore a SQL Server DB instance to a point in time, each database within that instance is restored to a point in time within 1 second of each other database within the instance. Transactions that span multiple databases within the instance might be restored inconsistently.
- For a SQL Server DB instance, the `OFFLINE`, `EMERGENCY`, and `SINGLE_USER` modes aren't supported. Setting any database into one of these modes causes the latest restorable time to stop moving ahead for the whole instance.
- Some actions, such as changing the recovery model of a SQL Server database, can break the sequence of logs that are used for point-in-time recovery. In some cases, Amazon RDS can detect this issue and the latest restorable time is prevented from moving forward. In other cases, such as when a SQL Server database uses the `BULK_LOGGED` recovery model, the break in log sequence isn't detected. It

might not be possible to restore a SQL Server DB instance to a point in time if there is a break in the log sequence. For these reasons, Amazon RDS doesn't support changing the recovery model of SQL Server databases.

Note

You can also use AWS Backup to manage backups of Amazon RDS DB instances. If your DB instance is associated with a backup plan in AWS Backup, that backup plan is used for point-in-time recovery. Backups that were created with AWS Backup have names ending in `awsbackup:AWS-Backup-job-number`. For information about AWS Backup, see the [AWS Backup Developer Guide](#).

You can restore a DB instance to a point in time using the AWS Management Console, the AWS CLI, or the RDS API.

Console

To restore a DB instance to a specified time

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Automated backups**.
3. Choose the DB instance that you want to restore.
4. For **Actions**, choose **Restore to point in time**.

The **Restore to point in time** window appears.

5. Choose **Latest restorable time** to restore to the latest possible time, or choose **Custom** to choose a time.

If you chose **Custom**, enter the date and time to which you want to restore the instance.

Note

Times are shown in your local time zone, which is indicated by an offset from Coordinated Universal Time (UTC). For example, UTC-5 is Eastern Standard Time/Central Daylight Time.

6. For **DB instance identifier**, enter the name of the target restored DB instance. The name must be unique.
7. Choose other options as needed, such as DB instance class, storage, and whether you want to use storage autoscaling.
8. Choose **Restore to point in time**.

AWS CLI

To restore a DB instance to a specified time, use the AWS CLI command `restore-db-instance-to-point-in-time` to create a new DB instance. This example also enables storage autoscaling.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-to-point-in-time \
--source-db-instance-identifier mysourcedbinstance \
--target-db-instance-identifier mytargetdbinstance \
--restore-time 2017-10-14T23:45:00.000Z \
--max-allocated-storage 1000
```

For Windows:

```
aws rds restore-db-instance-to-point-in-time ^
--source-db-instance-identifier mysourcedbinstance ^
--target-db-instance-identifier mytargetdbinstance ^
--restore-time 2017-10-14T23:45:00.000Z ^
--max-allocated-storage 1000
```

RDS API

To restore a DB instance to a specified time, call the Amazon RDS API [RestoreDBInstanceToPointInTime](#) operation with the following parameters:

- `SourceDBInstanceIdentifier`
- `TargetDBInstanceIdentifier`
- `RestoreTime`

Deleting a snapshot

You can delete DB snapshots managed by Amazon RDS when you no longer need them.

Note

To delete backups managed by AWS Backup, use the AWS Backup console. For information about AWS Backup, see the [AWS Backup Developer Guide](#).

Deleting a DB snapshot

You can delete a manual, shared, or public DB snapshot using the AWS Management Console, the AWS CLI, or the RDS API.

To delete a shared or public snapshot, you must sign in to the AWS account that owns the snapshot.

If you have automated DB snapshots that you want to delete without deleting the DB instance, change the backup retention period for the DB instance to 0. The automated snapshots are deleted when the change is applied. You can apply the change immediately if you don't want to wait until the next maintenance period. After the change is complete, you can then re-enable automatic backups by setting the backup retention period to a number greater than 0. For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

If you deleted a DB instance, you can delete its automated DB snapshots by removing the automated backups for the DB instance. For information about automated backups, see [Working with backups \(p. 328\)](#).

Console

To delete a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.

The **Manual snapshots** list appears.

3. Choose the DB snapshot that you want to delete.
4. For **Actions**, choose **Delete Snapshot**.
5. Choose **Delete** on the confirmation page.

AWS CLI

You can delete a DB snapshot by using the AWS CLI command `delete-db-snapshot`.

The following options are used to delete a DB snapshot.

- `--db-snapshot-identifier` – The identifier for the DB snapshot.

Example

The following code deletes the `mydbsnapshot` DB snapshot.

For Linux, macOS, or Unix:

```
aws rds delete-db-snapshot \
--db-snapshot-identifier mydbsnapshot
```

For Windows:

```
aws rds delete-db-snapshot ^
--db-snapshot-identifier mydbsnapshot
```

RDS API

You can delete a DB snapshot by using the Amazon RDS API operation [DeleteDBSnapshot](#).

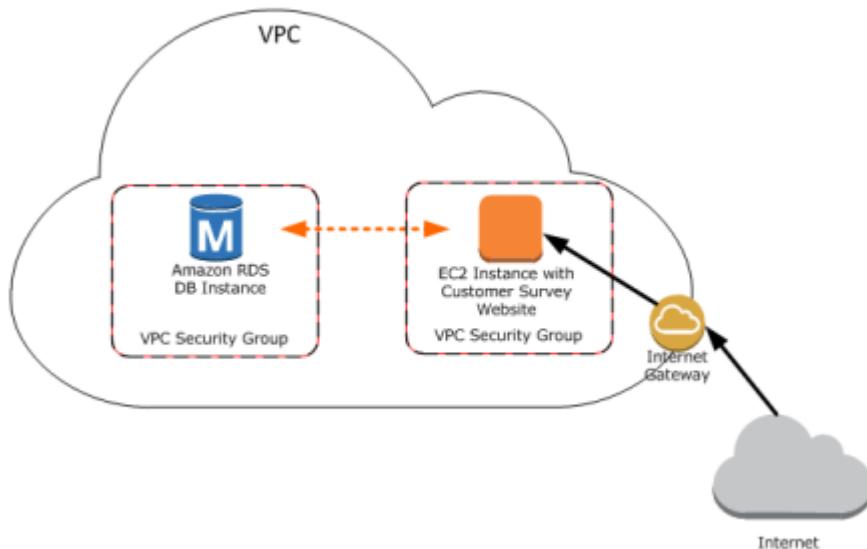

The following parameters are used to delete a DB snapshot.

- **DBSnapshotIdentifier** – The identifier for the DB snapshot.

Tutorial: Restore a DB instance from a DB snapshot

A common scenario when working with Amazon RDS is to have a DB instance that you work with occasionally but that you don't need full time. For example, you might have a quarterly customer survey that uses an Amazon Elastic Compute Cloud (Amazon EC2) instance to host a customer survey website and a DB instance that is used to store the survey results. One way to save money on such a scenario is to take a DB snapshot of the DB instance after the survey is completed, delete the DB instance, and then restore the DB instance when you need to conduct the survey again.

In the following illustration, you can see a possible scenario where an EC2 instance hosting a customer survey website is in the same Amazon Virtual Private Cloud (Amazon VPC) as a DB instance that retains the customer survey data. Note that each instance has its own security group; the EC2 instance security group allows access from the internet while the DB instance security group allows access only to and from the EC2 instance. When the survey is done, the EC2 instance can be stopped and the DB instance can be deleted after a final DB snapshot is created. When you need to conduct another survey, you can restart the EC2 instance and restore the DB instance from the DB snapshot.

For information about how to set up the needed VPC security groups for this scenario that allows the EC2 instance to connect with the DB instance, see [A DB instance in a VPC accessed by an EC2 instance in the same VPC \(p. 1720\)](#).

You must create a DB snapshot before you can restore a DB instance from one. When you restore the DB instance, you provide the name of the DB snapshot to restore from, and then provide a name for the new DB instance that is created from the restore operation. You cannot restore from a DB snapshot to an existing DB instance; a new DB instance is created when you restore.

Prerequisites for restoring a DB instance from a DB snapshot

Some settings on the restored DB instance are reset when the instance is restored, so you must retain the original resources to be able to restore the DB instance to its previous settings. For example, when you restore a DB instance from a DB snapshot, the default DB parameter and a default security group are associated with the restored instance. That association means that the default security group does not allow access to the DB instance, and no custom parameter settings are available in the default parameter group. You need to retain the DB parameter group and security group associated with the DB instance that was used to create the DB snapshot.

The following are required before you can restore a DB instance from a DB snapshot:

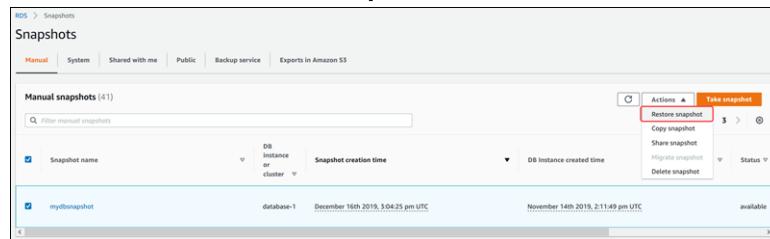

- You must have created a DB snapshot of a DB instance before you can restore a DB instance from that DB snapshot. For more information about creating a DB snapshot, see [Creating a DB snapshot \(p. 346\)](#).
- You must retain the parameter group and security group associated with the DB instance you created the DB snapshot from.
- You need to determine the correct option group for the restored DB instance:
 - The option group associated with the DB snapshot that you restore from is associated with the restored DB instance once it is created. For example, if the DB snapshot you restore from uses Oracle Transparent Data Encryption (TDE), the restored DB instance uses the same option group, which had the TDE option.
 - You cannot use the option group associated with the original DB instance if you attempt to restore that instance into a different VPC or into a different platform. This restriction occurs because when an option group is assigned to a DB instance, it is also linked to the platform that the DB instance is on, either VPC or EC2-Classic (non-VPC). If a DB instance is in a VPC, the option group associated with the instance is linked to that VPC.
 - If you restore a DB instance into a different VPC or onto a different platform, you must either assign the default option group to the instance, assign an option group that is linked to that VPC or platform, or create a new option group and assign it to the DB instance. Note that with persistent or permanent options, such as Oracle TDE, you must create a new option group that includes the persistent or permanent option when restoring a DB instance into a different VPC. For more information about working with option groups, see [Working with option groups \(p. 212\)](#).

Restoring a DB instance from a DB snapshot

You can use the procedure following to restore from a snapshot in the AWS Management Console.

To restore a DB instance from a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the DB snapshot that you want to restore from.
4. For **Actions**, choose **Restore snapshot**.

The **Restore snapshot** page appears.

5. For **DB Instance identifier** under **Settings**, enter the unique name that you want to use for the restored DB instance.

If you're restoring from a DB instance that you deleted after you made the DB snapshot, you can use the name of that DB instance.

6. Choose additional settings as needed.
7. Choose **Restore DB Instance**.

Modifying a restored DB instance

As soon as the restore operation is complete, you should associate the custom security group used by the instance you restored from with any applicable custom DB parameter group that you might have. Only the default DB parameter and security groups are associated with the restored instance. If you want to restore the functionality of the DB instance to that of the DB instance that the snapshot was created from, you must modify the DB instance to use the security group and parameter group used by the previous DB instance.

You must apply any changes explicitly using the RDS console's **Modify** command, the `ModifyDBInstance` API, or the `aws rds modify-db-instance` command line tool, once the DB instance is available. We recommend that you retain parameter groups for any DB snapshots you have so that you can associate a restored instance with the correct parameter file.

You can modify other settings on the restored DB instance. For example, you can use a different storage type than the source DB snapshot. In this case the restoration process is slower because of the additional work required to migrate the data to the new storage type. In the case of restoring to or from Magnetic (Standard) storage, the migration process is the slowest, because Magnetic storage does not have the IOPS capability of Provisioned IOPS or General Purpose (SSD) storage.

The next steps assume that your DB instance is in a VPC. If your DB instance is not in a VPC, use the AWS Management Console to locate the DB security group you need for the DB instance.

To modify a restored DB instance to have the settings of the original DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance created when you restored from the DB snapshot to display its details. Choose the **Connectivity** tab. The security group assigned to the DB instance might not allow access. If there are no inbound rules, no permissions exist that allow inbound access.

The screenshot shows the 'Connectivity' tab of the AWS RDS console. It displays three main sections: 'Endpoint & port', 'Networking', and 'Security'. In the 'Security' section, a red box highlights the 'VPC security groups' field, which lists '(active)' and 'rds-ca-2015'. Below this, it shows 'Public accessibility' set to 'Yes'.

Connectivity		
Endpoint & port	Networking	Security
Endpoint restored-db-instance.cahj48jpj34l.us-west-2.rds.amazonaws.com	Availability zone us-west-2a	VPC security groups (active)
Port 3306	VPC	Public accessibility Yes
	Subnet group default	Certificate authority rds-ca-2015
	Subnets	Certificate authority d... Mar 5th, 2020

Security group (1)

Filter security group rules

Security group	Type
[Redacted]	No applicable security group roles

4. Choose **Modify**.
5. In the **Network & Security** section, choose the security group that you want to use for your DB instance. If you need to add rules to create a new security group to use with an EC2 instance, see [A DB instance in a VPC accessed by an EC2 instance in the same VPC \(p. 1720\)](#) for more information.

You can also remove a security group by choosing the X associated with it.

The screenshot shows the 'Network & Security' configuration dialog. A red oval highlights the 'Select security groups' dropdown, which contains 'default ([]) ([]) X'. Other fields shown include 'Subnet group' (set to 'default'), 'Certificate authority' (set to 'rds-ca-2015'), and 'Public accessibility info' (set to 'Yes').

Network & Security

Subnet group
Use this field to move the DB instance to a new subnet group in another VPC. [Learn more.](#)

default

Security group
List of DB security groups to associate with this DB instance.

Select security groups

default ([]) ([]) X

Certificate authority
Certificate authority for this DB instance

rds-ca-2015

Public accessibility info

Yes
EC2 instances and devices outside of the VPC hosting the DB instance will connect to the DB instances. You must also select one or more VPC security groups that specify which EC2 instances and devices can connect to the DB instance.

No
DB instance will not have a public IP address assigned. No EC2 instance or devices outside of the VPC will be able to connect.

6. Choose **Continue**, and then choose **Apply immediately**.
7. Choose **Modify DB Instance**.

After the instance status is available, choose the DB instance name to display its details. Choose the **Connectivity** tab, and confirm that the new security group has been applied, making the DB instance authorized for access.

The screenshot shows the 'Connectivity' tab selected in the top navigation bar of the AWS RDS console. The page displays three main sections: 'Endpoint & port', 'Networking', and 'Security'. The 'Security' section is highlighted with a red oval, specifically focusing on the 'VPC security groups' field which lists 'rds-launch-wizard-9 (active)'. Other visible details include the endpoint 'restored-db-instance.cahj48jp34l.us-west-2.rds.amazonaws.com' and port '3306' under 'Endpoint & port'; 'us-west-2a' under 'Availability zone'; and 'Subnet group default' under 'Networking'.

Monitoring an Amazon RDS DB instance

This section shows you how to monitor Amazon RDS.

Overview of monitoring Amazon RDS

Monitoring is an important part of maintaining the reliability, availability, and performance of Amazon RDS and your AWS solutions. To more easily debug multi-point failures, we recommend that you collect monitoring data from all parts of your AWS solution.

Monitoring plan

Before you start monitoring Amazon RDS, create a monitoring plan. This plan should answer the following questions:

- What are your monitoring goals?
- Which resources will you monitor?
- How often will you monitor these resources?
- Which monitoring tools will you use?
- Who will perform the monitoring tasks?
- Whom should be notified when something goes wrong?

Performance baseline

To achieve your monitoring goals, you need to establish a baseline. To do this, measure performance under different load conditions at various times in your Amazon RDS environment. You can monitor metrics such as the following:

- Network throughput
- Client connections
- I/O for read, write, or metadata operations
- Burst credit balances for your DB instances

We recommend that you store historical performance data for Amazon RDS. Using the stored data, you can compare current performance against past trends. You can also distinguish normal performance patterns from anomalies, and devise techniques to address issues.

Performance guidelines

In general, acceptable values for performance metrics depend on what your application is doing relative to your baseline. Investigate consistent or trending variances from your baseline. The following metrics are often the source of performance issues:

- **High CPU or RAM consumption** – High values for CPU or RAM consumption might be appropriate, if they're in keeping with your goals for your application (like throughput or concurrency) and are expected.
- **Disk space consumption** – Investigate disk space consumption if space used is consistently at or above 85 percent of the total disk space. See if it is possible to delete data from the instance or archive data to a different system to free up space.
- **Network traffic** – For network traffic, talk with your system administrator to understand what expected throughput is for your domain network and internet connection. Investigate network traffic if throughput is consistently lower than expected.
- **Database connections** – If you see high numbers of user connections and also decreases in instance performance and response time, consider constraining database connections. The best number of

user connections for your DB instance varies based on your instance class and the complexity of the operations being performed. To determine the number of database connections, associate your DB instance with a parameter group where the `User_Connections` parameter is set to a value other than 0 (unlimited). You can either use an existing parameter group or create a new one. For more information, see [Working with DB parameter groups \(p. 228\)](#).

- **IOPS metrics** – The expected values for IOPS metrics depend on disk specification and server configuration, so use your baseline to know what is typical. Investigate if values are consistently different than your baseline. For best IOPS performance, make sure that your typical working set fits into memory to minimize read and write operations.

When performance falls outside your established baseline, you might need to make changes to optimize your database availability for your workload. For example, you might need to change the instance class of your DB instance. Or you might need to change the number of DB instances and read replicas that are available for clients.

Monitoring tools

AWS provides various tools that you can use to monitor Amazon RDS. You can configure some of these tools to do the monitoring for you, and other tools require manual intervention.

Automated monitoring tools

We recommend that you automate monitoring tasks as much as possible.

Amazon RDS reporting tools

You can use the following automated tools to watch Amazon RDS and report when something is wrong:

- **Amazon RDS instance status** — View details about the current status of your instance by using the Amazon RDS console, the AWS CLI command, or the RDS API.
- **Amazon RDS recommendations** — Respond to automated recommendations for database resources, such as DB instances, read replicas, and DB parameter groups. For more information, see [Using Amazon RDS recommendations \(p. 407\)](#).
- **Amazon RDS Performance Insights** — Assess the load on your database, and determine when and where to take action. For more information, see [Using Performance Insights on Amazon RDS \(p. 412\)](#).
- **Amazon RDS Enhanced Monitoring** — Look at metrics in real time for the operating system. For more information, see [Using Enhanced Monitoring \(p. 471\)](#).
- **Amazon RDS events** — Subscribe to Amazon RDS events to be notified when changes occur with a DB instance, DB snapshot, DB parameter group, or DB security group. For more information, see [Using Amazon RDS event notification \(p. 487\)](#).
- **Amazon RDS database logs** — View, download, or watch database log files using the Amazon RDS console or Amazon RDS API operations. You can also query some database log files that are loaded into database tables. For more information, see [Accessing Amazon RDS database log files \(p. 504\)](#).

Integrated monitoring tools

Amazon RDS integrates with Amazon CloudWatch, Amazon EventBridge, and AWS CloudTrail for additional monitoring capabilities.

- **Amazon CloudWatch** – This service monitors your AWS resources and the applications you run on AWS in real time. You can use the following Amazon CloudWatch features with Amazon RDS:
 - **Amazon CloudWatch metrics** – Amazon RDS automatically sends metrics to CloudWatch every minute for each active database. You don't get additional charges for Amazon RDS metrics

in CloudWatch. For more information, see [Monitoring Amazon RDS metrics with Amazon CloudWatch \(p. 540\)](#).

- **Amazon CloudWatch alarms** – You can watch a single Amazon RDS metric over a specific time period. You can then perform one or more actions based on the value of the metric relative to a threshold that you set. For more information, see [Monitoring Amazon RDS metrics with Amazon CloudWatch \(p. 540\)](#).
- **Amazon CloudWatch Logs** – Most DB engines enable you to monitor, store, and access your database log files in CloudWatch Logs. For more information, see [Amazon CloudWatch Logs User Guide](#).
- **Amazon EventBridge** – is a serverless event bus service that makes it easy to connect your applications with data from a variety of sources. EventBridge delivers a stream of real-time data from your own applications, Software-as-a-Service (SaaS) applications, and AWS services and routes that data to targets such as Lambda. This enables you to monitor events that happen in services, and build event-driven architectures. For more information, see [Getting CloudWatch Events and Amazon EventBridge events for Amazon RDS \(p. 551\)](#).
- **AWS CloudTrail** – You can view a record of actions taken by a user, role, or an AWS service in Amazon RDS. CloudTrail captures all API calls for Amazon RDS as events. These captures include calls from the Amazon RDS console and from code calls to the Amazon RDS API operations. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Amazon RDS. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. For more information, see [Working with AWS CloudTrail and Amazon RDS \(p. 557\)](#).

Manual monitoring tools

You need to manually monitor those items that the CloudWatch alarms don't cover. The Amazon RDS, CloudWatch, AWS Trusted Advisor and other AWS console dashboards provide an at-a-glance view of the state of your AWS environment. We recommend that you also check the log files on your DB instance.

- From the Amazon RDS console, you can monitor the following items for your resources:
 - The number of connections to a DB instance
 - The amount of read and write operations to a DB instance
 - The amount of storage that a DB instance is currently using
 - The amount of memory and CPU being used for a DB instance
 - The amount of network traffic to and from a DB instance
- From the Trusted Advisor dashboard, you can review the following cost optimization, security, fault tolerance, and performance improvement checks:
 - Amazon RDS Idle DB Instances
 - Amazon RDS Security Group Access Risk
 - Amazon RDS Backups
 - Amazon RDS Multi-AZ

For more information on these checks, see [Trusted Advisor best practices \(checks\)](#).

- CloudWatch home page shows:
 - Current alarms and status
 - Graphs of alarms and resources
 - Service health status

In addition, you can use CloudWatch to do the following:

- Create [customized dashboards](#) to monitor the services that you care about.
- Graph metric data to troubleshoot issues and discover trends.
- Search and browse all your AWS resource metrics.

- Create and edit alarms to be notified of problems.

DB instance status

The status of a DB instance indicates the health of the DB instance. You can view the status of a DB instance by using the Amazon RDS console, the AWS CLI command [describe-db-instances](#), or the API operation [DescribeDBInstances](#).

Note

Amazon RDS also uses another status called *maintenance status*, which is shown in the **Maintenance** column of the Amazon RDS console. This value indicates the status of any maintenance patches that need to be applied to a DB instance. Maintenance status is independent of DB instance status. For more information on *maintenance status*, see [Applying updates for a DB instance \(p. 266\)](#).

Find the possible status values for DB instances in the following table, which also shows how you are billed for each status. It shows if you will be billed for the DB instance and storage, billed only for storage, or not billed. For all DB instance statuses, you are always billed for backup usage.

DB instance status	Billed	Description
available	Billed	The DB instance is healthy and available.
backing-up	Billed	The DB instance is currently being backed up.
backtracking	Billed	The DB instance is currently being backtracked. This status only applies to Aurora MySQL.
configuring-enhanced-monitoring	Billed	Enhanced Monitoring is being enabled or disabled for this DB instance.
configuring-iam-database-auth	Billed	AWS Identity and Access Management (IAM) database authentication is being enabled or disabled for this DB instance.
configuring-log-exports	Billed	Publishing log files to Amazon CloudWatch Logs is being enabled or disabled for this DB instance.
converting-to-vpc	Billed	The DB instance is being converted from a DB instance that is not in an Amazon Virtual Private Cloud (Amazon VPC) to a DB instance that is in an Amazon VPC.
creating	Not billed	The DB instance is being created. The DB instance is inaccessible while it is being created.
deleting	Not billed	The DB instance is being deleted.
failed	Not billed	The DB instance has failed and Amazon RDS can't recover it. Perform a point-in-time restore to the latest restorable time of the DB instance to recover the data.
inaccessible-encryption-credentials	Not billed	The AWS KMS customer master key (CMK) used to encrypt or decrypt the DB instance can't be accessed.
incompatible-network	Not billed	Amazon RDS is attempting to perform a recovery action on a DB instance but can't do so because the VPC is in a state that prevents the action from being completed. This status can occur if, for example, all available IP addresses in a subnet are in use and Amazon RDS can't get an IP address for the DB instance.

DB instance status	Billed	Description
incompatible-option-group	Billed	Amazon RDS attempted to apply an option group change but can't do so, and Amazon RDS can't roll back to the previous option group state. For more information, check the Recent Events list for the DB instance. This status can occur if, for example, the option group contains an option such as TDE and the DB instance doesn't contain encrypted information.
incompatible-parameters	Billed	Amazon RDS can't start the DB instance because the parameters specified in the DB instance's DB parameter group aren't compatible with the DB instance. Revert the parameter changes or make them compatible with the DB instance to regain access to your DB instance. For more information about the incompatible parameters, check the Recent Events list for the DB instance.
incompatible-restore	Not billed	Amazon RDS can't do a point-in-time restore. Common causes for this status include using temp tables, using MyISAM tables with MySQL, or using Aria tables with MariaDB.
insufficient-capacity		Amazon RDS can't create your instance because sufficient capacity isn't currently available. To create your DB instance in the same AZ with the same instance type, delete your DB instance, wait a few hours, and try to create again. Alternatively, create a new instance using a different instance class or AZ.
maintenance	Billed	Amazon RDS is applying a maintenance update to the DB instance. This status is used for instance-level maintenance that RDS schedules well in advance.
modifying	Billed	The DB instance is being modified because of a customer request to modify the DB instance.
moving-to-vpc	Billed	The DB instance is being moved to a new Amazon Virtual Private Cloud (Amazon VPC).
rebooting	Billed	The DB instance is being rebooted because of a customer request or an Amazon RDS process that requires the rebooting of the DB instance.
resetting-master-credentials	Billed	The master credentials for the DB instance are being reset because of a customer request to reset them.
renaming	Billed	The DB instance is being renamed because of a customer request to rename it.
restore-error	Billed	The DB instance encountered an error attempting to restore to a point-in-time or from a snapshot.
starting	Billed for storage	The DB instance is starting.
stopped	Billed for storage	The DB instance is stopped.

DB instance status	Billed	Description
stopping	Billed for storage	The DB instance is being stopped.
storage-full	Billed	The DB instance has reached its storage capacity allocation. This is a critical status, and we recommend that you fix this issue immediately. To do so, scale up your storage by modifying the DB instance. To avoid this situation, set Amazon CloudWatch alarms to warn you when storage space is getting low.
storage-optimization	Billed	Your DB instance is being modified to change the storage size or type. The DB instance is fully operational. However, while the status of your DB instance is storage-optimization , you can't request any changes to the storage of your DB instance. The storage optimization process is usually short, but can sometimes take up to and even beyond 24 hours.
upgrading	Billed	The database engine version is being upgraded.

Using Amazon RDS recommendations

Amazon RDS provides automated recommendations for database resources, such as DB instances, read replicas, and DB parameter groups. These recommendations provide best practice guidance by analyzing DB instance configuration, usage, and performance data.

You can find examples of these recommendations in the following table.

Type	Description	Recommendation	Additional information
Engine version outdated	Your DB instance is not running the latest minor engine version.	We recommend that you upgrade to the latest version because it contains the latest security fixes and other improvements.	Upgrading a DB instance engine version (p. 271)
Pending maintenance available	You have pending maintenance available on your DB instance.	We recommend that you perform the pending maintenance available on your DB instance. Updates to the operating system most often occur for security issues and should be done as soon as possible.	Maintaining a DB instance (p. 264)
Automated backups disabled	Your DB instance has automated backups disabled.	We recommend that you enable automated backups on your DB instance. Automated backups enable point-in-time recovery of your DB instance. You receive backup storage up to the storage size of your DB instance at no additional charge.	Working with backups (p. 328)
Magnetic volumes in use	Your DB instance is using magnetic storage.	Magnetic storage is not recommended for most DB instances. We recommend switching to General Purpose (SSD) storage or provisioned IOPS storage.	Amazon RDS DB instance storage (p. 40)
EC2-Classic platform in use	Your DB instance is using the legacy EC2-Classic platform.	We recommend moving your DB instance to the EC2-VPC platform for better network access control. Amazon VPC provides a virtual network that is logically isolated from other virtual networks in the AWS Cloud.	Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1718)
Enhanced Monitoring disabled	Your DB instance doesn't have Enhanced Monitoring enabled.	We recommend enabling Enhanced Monitoring. Enhanced Monitoring provides real-time operating system metrics for monitoring and troubleshooting.	Using Enhanced Monitoring (p. 471)
Encryption disabled	Your DB instance doesn't have encryption enabled.	We recommend enabling encryption. You can encrypt your existing Amazon RDS DB instances by restoring from an encrypted snapshot.	Encrypting Amazon RDS resources (p. 1630)
Previous generation	Your DB instance is running on a	Previous-generation DB instance classes have been replaced by DB	DB instance classes (p. 7)

Type	Description	Recommendation	Additional information
DB instance class in use	previous-generation DB instance class.	instance classes with better price, better performance, or both. We recommend running your DB instance on a later generation DB instance class.	
Huge pages not used for an Oracle DB instance	The <code>use_large_pages</code> parameter is not set to <code>ONLY</code> in the DB parameter group used by your DB instance.	For increased database scalability, we recommend setting <code>use_large_pages</code> to <code>ONLY</code> in the DB parameter group used by your DB instance.	Enabling HugePages for an Oracle DB instance (p. 1101)
Nondefault custom memory parameters	Your DB parameter group sets memory parameters that diverge too much from the default values.	Settings that diverge too much from the default values can cause poor performance and errors. We recommend setting custom memory parameters to their default values in the DB parameter group used by the DB instance.	Working with DB parameter groups (p. 228)
Change buffering enabled for a MySQL DB instance	Your DB parameter group has change buffering enabled.	Change buffering allows a MySQL DB instance to defer some writes necessary to maintain secondary indexes. This configuration can improve performance slightly, but it can create a large delay in crash recovery. During crash recovery, the secondary index must be brought up to date. So, the benefits of change buffering are outweighed by the potentially very long crash recovery events. We recommend disabling change buffering.	Best practices for configuring parameters for Amazon RDS for MySQL, part 1: Parameters related to performance on the AWS Database Blog
Query cache enabled for a MySQL DB instance	Your DB parameter group has query cache parameter enabled.	The query cache can cause the DB instance to appear to stall when changes require the cache to be purged. Most workloads don't benefit from a query cache. The query cache was removed from MySQL version 8.0. We recommend that you disable the query cache parameter.	Best practices for configuring parameters for Amazon RDS for MySQL, part 1: Parameters related to performance on the AWS Database Blog
Logging to table	Your DB parameter group sets logging output to <code>TABLE</code> .	Setting logging output to <code>TABLE</code> uses more storage than setting this parameter to <code>FILE</code> . To avoid reaching the storage limit, we recommend setting the logging output parameter to <code>FILE</code> .	Accessing MySQL database log files (p. 519)

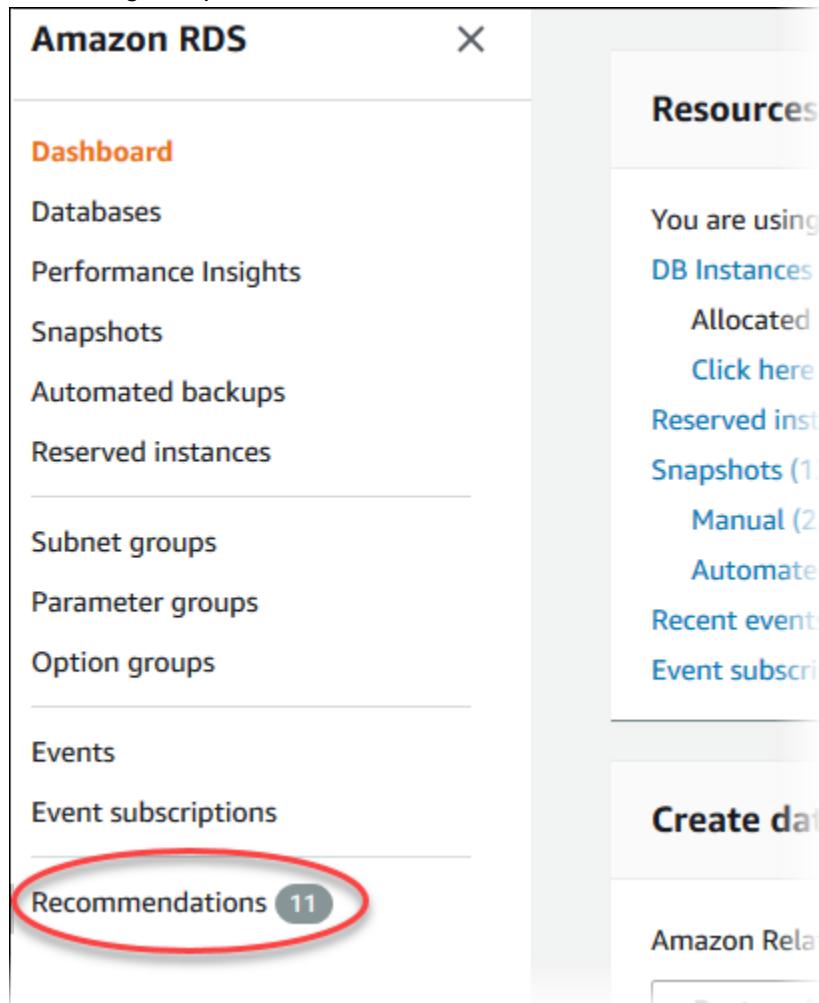

Amazon RDS generates recommendations for a resource when the resource is created or modified. Amazon RDS also periodically scans your resources and generates recommendations.

Responding to Amazon RDS recommendations

You can find recommendations in the AWS Management Console. You can perform the recommended action immediately, schedule it for the next maintenance window, or dismiss it.

To respond to Amazon RDS recommendations

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Recommendations**.

The Recommendations page appears.

The screenshot shows a 'Recommendations' page with a header bar containing four tabs: Active (2), Dismissed (0), Scheduled (0), and Applied (1). The Active tab is selected. Below the tabs, there are two main sections: 'Engine version outdated for DB instances (1)' and 'Enhanced monitoring disabled (1)'. Each section contains a brief description and a 'Info' link.

3. On the **Recommendations** page, choose one of the following:

- **Active** – Shows the current recommendations that you can apply, dismiss, or schedule.
- **Dismissed** – Shows the recommendations that have been dismissed. When you choose **Dismissed**, you can apply these dismissed recommendations.
- **Scheduled** – Shows the recommendations that are scheduled but not yet applied. These recommendations will be applied in the next scheduled maintenance window.
- **Applied** – Shows the recommendations that are currently applied.

From any list of recommendations, you can open a section to view the recommendations in that section.

The screenshot shows the 'Engine version outdated for DB instances (1)' section from the previous screenshot. It includes a 'DB instances' heading, a search bar, and a table with columns for Resource and Recommendation. One row in the table is for 'database-1', which has a note about upgrading to mysql version 5.6.41. There are also buttons for Dismiss, Schedule, and Apply now.

To configure preferences for displaying recommendations in each section, choose the **Preferences** icon.

Recommendations

Active (2) Dismissed (0) Scheduled (0) Applied (1)

▼ Engine version outdated for DB instances (1)
DB instances that are not running the latest minor engine version. [Info](#)

DB instances

Filter recommendations

<input type="checkbox"/>	Resource	Recommendation	Actions
<input type="checkbox"/>	database-1	Your DB instance is running mysql version 5.6.34. We recommend that you upgrade to version 5.6.41 because it contains the latest security fixes and other improvements.	Dismiss Schedule Apply now

► Enhanced monitoring disabled (1)
DB instances that don't have Enhanced Monitoring enabled. [Info](#)

From the **Preferences** window that appears, you can set display options. These options include the visible columns and the number of recommendations to display on the page.

4. Manage your active recommendations:

- Choose **Active** and open one or more sections to view the recommendations in them.
- Choose one or more recommendations and choose **Apply now** (to apply them immediately), **Schedule** (to apply them in next maintenance window), or **Dismiss**.

If the **Apply now** button appears for a recommendation but is unavailable (grayed out), the DB instance is not available. You can apply recommendations immediately only if the DB instance status is **available**. For example, you can't apply recommendations immediately to the DB instance if its status is **modifying**. In this case, wait for the DB instance to be available and then apply the recommendation.

If the **Apply now** button doesn't appear for a recommendation, you can't apply the recommendation using the **Recommendations** page. You can modify the DB instance to apply the recommendation manually.

For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

Note

When you choose **Apply now**, a brief DB instance outage might result.

Using Performance Insights on Amazon RDS

Performance Insights expands on existing Amazon RDS monitoring features to illustrate your database's performance and help you analyze any issues that affect it. With the Performance Insights dashboard, you can visualize the database load and filter the load by waits, SQL statements, hosts, or users.

Topics

- [Overview of Performance Insights \(p. 412\)](#)
- [Enabling and disabling Performance Insights \(p. 415\)](#)
- [Accessing Performance Insights \(p. 419\)](#)
- [Monitoring with the Performance Insights dashboard \(p. 421\)](#)
- [Customizing the Performance Insights dashboard \(p. 444\)](#)
- [Retrieving data with the Performance Insights API \(p. 454\)](#)
- [Performance Insights metrics published to Amazon CloudWatch \(p. 467\)](#)
- [Logging Performance Insights calls by using AWS CloudTrail \(p. 468\)](#)

Overview of Performance Insights

By default, Performance Insights is enabled in the console create wizard for Amazon RDS engines. If you have more than one database on a DB instance, Performance Insights aggregates performance data.

Topics

- [DB load \(p. 412\)](#)
- [Maximum CPU \(p. 414\)](#)
- [DB engine support for Performance Insights \(p. 414\)](#)
- [AWS Region support for Performance Insights \(p. 415\)](#)

DB load

The central metric for Performance Insights is DB Load. The DB Load metric is collected every second.

Active Sessions

An *active session* is a connection that has submitted work to the DB engine and is waiting for a response. The DB load represents the *average active sessions* (AAS) for the DB engine. For example, if you submit a SQL query to the DB engine, the database session is active while the engine is processing the query.

To obtain the AAS, Performance Insights samples the number of sessions concurrently running a query. The AAS is the total number of sessions divided by the total number of samples. The following table shows 5 consecutive samples of a running query.

Sample	Number of sessions running query	AAS	Calculation
1	2	2	2 sessions / 1 sample
2	0	1	2 sessions / 2 samples
3	4	2	6 sessions / 3 samples
4	0	1.5	6 sessions / 4 samples

Sample	Number of sessions running query	AAS	Calculation
5	4	2	10 sessions / 5 samples

Related to AAS is the *average active executions (AAE)* per second. To calculate the AAE, Performance Insights divides the total execution time of a query by the time interval. The following table shows the AAE calculation for the same query in the preceding table.

Elapsed time (s)	Total execution time (s)	AAE	Calculation
60	120	2	120 execution seconds / 60 elapsed seconds
120	120	1	120 execution seconds / 120 elapsed seconds
180	380	2.11	360 execution seconds / 180 elapsed seconds
240	380	1.58	360 execution seconds / 240 elapsed seconds
300	600	2	600 execution seconds / 300 elapsed seconds

In most cases, the AAS and AAE for a query are approximately the same. However, because the inputs to the calculations are different data sources, the calculations often vary slightly.

Dimensions

The `DB_Load` metric has subcomponents called *dimensions*. You can think of dimensions as categories for the different characteristics of the `DB_Load` metric. When you are diagnosing performance issues, the most useful dimensions are wait events and top SQL.

Wait events

A *wait event* causes a SQL statement to wait for a specific event to happen before it can continue running. For example, a SQL statement might wait until a locked resource is unlocked. By combining `DB_Load` with wait events, you can get a complete picture of the session state. Wait events vary by DB engine:

- For information about all MariaDB and MySQL wait events, see [Wait Event Summary Tables](#) in the MySQL documentation.
- For information about all PostgreSQL wait events, see [PostgreSQL Wait Events](#) in the PostgreSQL documentation.
- For information about all Oracle wait events, see [Descriptions of Wait Events](#) in the Oracle documentation.
- For information about all SQL Server wait events, see [Types of Waits](#) in the SQL Server documentation.

Note

For Oracle, background processes sometimes do work without an associated SQL statement. In these cases, Performance Insights reports the type of background process concatenated with a

colon and the wait class associated with that background process. Types of background process include LGWR, ARC0, PMON, and so on.

For example, when the archiver is performing I/O, the Performance Insights report for it is similar to `ARC1 : System I/O`. Occasionally, the background process type is also missing, and Performance Insights only reports the wait class, for example `:System I/O`.

Top SQL

Whereas wait events show bottlenecks, top SQL shows which queries are contributing the most to DB load. For example, many queries might be currently running on the database, but a single query might consume 99% of the DB load. In this case, the high load might indicate a problem with the query.

By default, the Performance Insights console displays top SQL queries that are contributing to the database load. The console also shows relevant statistics for each statement. To diagnose performance problems for a specific statement, you can examine its execution plan.

Maximum CPU

In the dashboard, the **Database load** chart collects, aggregates, and displays session information. To see whether active sessions are exceeding the maximum CPU, look at their relationship to the **Max vCPU** line. The **Max vCPU** value is determined by the number of vCPU (virtual CPU) cores for your DB instance.

If the load is often above the **Max vCPU** line, and the primary wait state is CPU, the system CPU is overloaded. In these cases, you might want to throttle connections to the instance, tune any SQL queries with a high CPU load, or consider a larger instance class. High and consistent instances of any wait state indicate that there might be bottlenecks or resource contention issues to resolve. This can be true even if the load doesn't cross the **Max vCPU** line.

You can find an overview of Performance Insights in the following video.

[Using Performance Insights to Analyze Performance of Amazon Aurora PostgreSQL](#)

DB engine support for Performance Insights

Following, you can find the DB engines that support Performance Insights.

DB Engine	Supported DB Engine Versions
Amazon RDS for MariaDB	All 10.5 versions, all 10.4 versions, 10.3.13 and higher 10.3 versions, and 10.2.21 and higher 10.2 versions. Not supported for MariaDB version 10.0 or 10.1. Not supported for MariaDB version 10.3.13 DB instances in the Europe (Frankfurt) and Europe (Stockholm) AWS Regions. Not supported on the following DB instance classes: db.t2.micro, db.t2.small, db.t3.micro, and db.t3.small.
Amazon RDS for MySQL	8.0.17 and higher 8.0 versions, version 5.7.22 and higher 5.7 versions, and version 5.6.41 and higher 5.6 versions. Not supported for version 5.5. Not supported on the following DB instance classes: db.t2.micro, db.t2.small, db.t3.micro, and db.t3.small.
Amazon RDS for Microsoft SQL Server	All versions except SQL Server 2008.
Amazon RDS for PostgreSQL	Versions 10, 11, 12, and 13.

DB Engine	Supported DB Engine Versions
	is
Amazon RDS for Oracle	All versions.

AWS Region support for Performance Insights

Performance Insights for Amazon RDS isn't supported in the following AWS Regions:

- Middle East (Bahrain) Region
- Europe (Milan) Region
- Africa (Cape Town) Region
- Asia Pacific (Osaka)
- AWS GovCloud (US) Regions

Important

This guide describes using Amazon RDS Performance Insights with non-Aurora DB engines. For information about using Amazon RDS Performance Insights with Amazon Aurora, see the [Using Amazon RDS Performance Insights](#) in the *Amazon Aurora User Guide*.

Enabling and disabling Performance Insights

To use Performance Insights, enable it on your DB instance. If needed, you can disable it later. Enabling and disabling Performance Insights doesn't cause downtime, a reboot, or a failover.

The Performance Insights agent consumes limited CPU and memory on the DB host. When the DB load is high, the agent limits the performance impact by collecting data less frequently.

Console

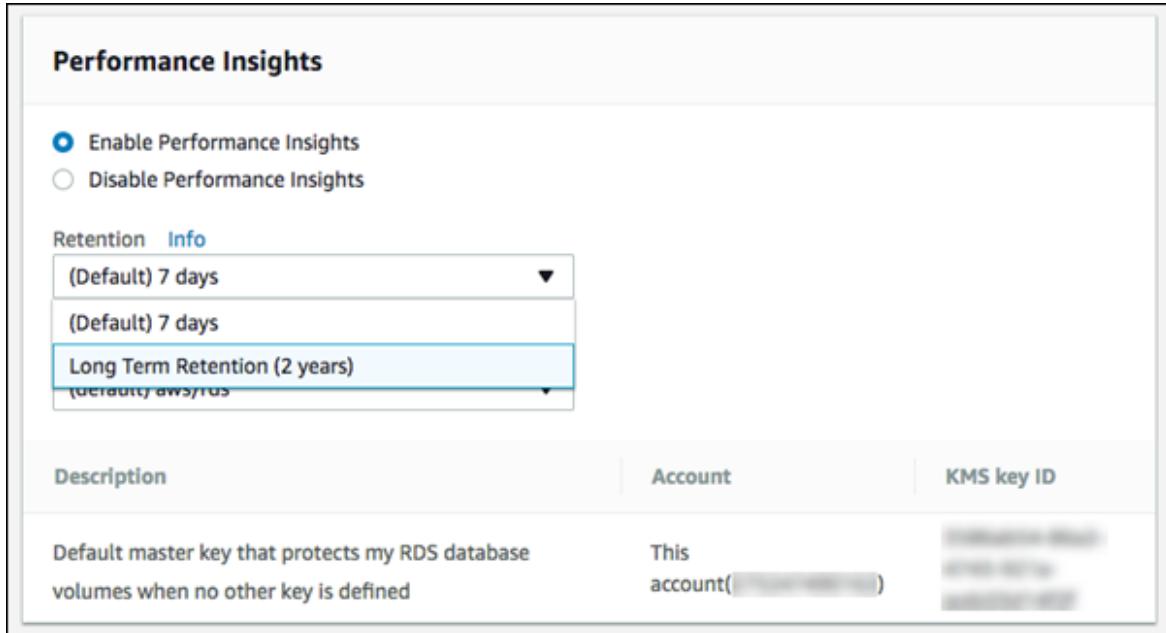

In the console, you can enable or disable Performance Insights when you create or modify a new DB instance.

[Enabling or disabling Performance Insights when creating an instance](#)

When you create a new DB instance, enable Performance Insights by choosing **Enable Performance Insights** in the **Performance Insights** section. Or choose **Disable Performance Insights**.

To create a DB instance, follow the instructions for your DB engine in [Creating an Amazon RDS DB instance \(p. 141\)](#).

The following screenshot shows the **Performance Insights** section.

If you choose **Enable Performance Insights**, you have the following options:

- **Retention** – The amount of time to retain Performance Insights data. Choose either 7 days (the default) or 2 years.
- **Master key** – Specify your AWS Key Management Service (AWS KMS) customer master key (CMK). Performance Insights encrypts all potentially sensitive data using your AWS KMS CMK. Data is encrypted in flight and at rest. For more information, see [Encrypting Amazon RDS resources \(p. 1630\)](#).

[Enabling or disabling Performance Insights when modifying an instance](#)

In the console, you can modify a DB instance to enable or disable Performance Insights using the console.

To enable or disable Performance Insights for a DB instance using the console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Databases**.
3. Choose a DB instance, and choose **Modify**.
4. In the **Performance Insights** section, choose either **Enable Performance Insights** or **Disable Performance Insights**.

If you choose **Enable Performance Insights**, you have the following options:

- **Retention** – The amount of time to retain Performance Insights data. Choose either 7 days (the default) or 2 years.
 - **Master key** – Specify your AWS Key Management Service (AWS KMS) customer master key (CMK). Performance Insights encrypts all potentially sensitive data using your AWS KMS CMK. Data is encrypted in flight and at rest. For more information, see [Encrypting Amazon RDS resources \(p. 1630\)](#).
5. Choose **Continue**.
 6. For **Scheduling of Modifications**, choose one of the following:

- **Apply during the next scheduled maintenance window** – Wait to apply the **Performance Insights** modification until the next maintenance window.
 - **Apply immediately** – Apply the **Performance Insights** modification as soon as possible.
7. Choose **Modify instance**.

AWS CLI

When you use the [create-db-instance](#) AWS CLI command, enable Performance Insights by specifying `--enable-performance-insights`. Or disable Performance Insights by specifying `--no-enable-performance-insights`.

You can also specify these values using the following AWS CLI commands:

- [create-db-instance-read-replica](#)
- [modify-db-instance](#)
- [restore-db-instance-from-s3](#)

The following procedure describes how to enable or disable Performance Insights for a DB instance using the AWS CLI.

To enable or disable Performance Insights for a DB instance using the AWS CLI

- Call the [modify-db-instance](#) AWS CLI command and supply the following values:
 - `--db-instance-identifier` – The name of the DB instance.
 - `--enable-performance-insights` to enable or `--no-enable-performance-insights` to disable

The following example enables Performance Insights for `sample-db-instance`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier sample-db-instance \
  --enable-performance-insights
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier sample-db-instance ^
  --enable-performance-insights
```

When you enable Performance Insights, you can optionally specify the amount of time, in days, to retain Performance Insights data with the `--performance-insights-retention-period` option. Valid values are 7 (the default) or 731 (2 years).

The following example enables Performance Insights for `sample-db-instance` and specifies that Performance Insights data is retained for two years.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier sample-db-instance \
```

```
--enable-performance-insights \
--performance-insights-retention-period 731
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier sample-db-instance ^
--enable-performance-insights ^
--performance-insights-retention-period 731
```

RDS API

When you create a new DB instance using the [CreateDBInstance](#) operation Amazon RDS API operation, enable Performance Insights by setting `EnablePerformanceInsights` to `True`. To disable Performance Insights, set `EnablePerformanceInsights` to `False`.

You can also specify the `EnablePerformanceInsights` value using the following API operations:

- [ModifyDBInstance](#)
- [CreateDBInstanceReadReplica](#)
- [RestoreDBInstanceFromS3](#)

When you enable Performance Insights, you can optionally specify the amount of time, in days, to retain Performance Insights data with the `PerformanceInsightsRetentionPeriod` parameter. Valid values are 7 (the default) or 731 (2 years).

Enabling the Performance Schema for Performance Insights on Amazon RDS for MariaDB or MySQL

When the Performance Schema is enabled for Amazon RDS for MariaDB or MySQL, Performance Insights provides more detailed information. For example, Performance Insights displays DB load categorized by detailed wait events. When Performance Schema isn't enabled, Performance Insights displays DB load categorized by the list state of the MySQL process.

You have the following options for enabling the Performance Schema:

- Allow Performance Insights to manage required parameters automatically.

When you create an Amazon RDS for MariaDB or MySQL DB instance with Performance Insights enabled, Performance Schema is enabled automatically. In this case, Performance Insights automatically manages your parameters.

Important

In this scenario, Performance Insights changes schema-related parameters on the DB instance. These changes aren't visible in the parameter group associated with the DB instance. However, these changes are visible in the output of the `SHOW GLOBAL VARIABLES` command.

- Set the required parameters yourself.

For Performance Insights to list wait events, you must set all parameters as shown in the following table.

Parameter Name	Parameter Value
<code>performance_schema</code>	1 (the <code>Source</code> column has the value <code>engine-default</code>)

Parameter Name	Parameter Value
performance-schema-consumer-events-waits-current	ON
performance-schema-instrument	wait/%=ON
performance-schema-consumer-global-instrumentation	ON
performance-schema-consumer-thread-instrumentation	ON

For more information, see [Performance Schema Command Options](#) and [Performance Schema Option and Variable Reference](#) in the MySQL documentation.

Enabling the Performance Schema manually

Performance Schema is *not* enabled when both the following conditions are true:

- The `performance_schema` parameter is set to 0 or 1.
- The **Source** column for the `performance_schema` parameter is set to `user`.

To enable the Performance Schema manually

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose **Parameter groups**.
3. Select the name of the parameter group for your DB instance.
4. Choose **Edit parameters**.
5. Enter `perf` in the search bar.
6. Select the `performance_schema` parameter.
A screenshot of the AWS RDS Parameter Group configuration screen. A blue rectangular box highlights the 'performance_schema' parameter. To its left is a checked checkbox icon. The parameter name 'performance_schema' is displayed to the right of the checkbox.
7. Choose **Reset**.
8. Choose **Reset parameters**.
9. Restart the DB instance.

For more information about modifying instance parameters, see [Modifying parameters in a DB parameter group \(p. 232\)](#). For more information about the dashboard, see [Monitoring with the Performance Insights dashboard \(p. 421\)](#). For more information about the MySQL performance schema, see [MySQL 8.0 Reference Manual](#).

Accessing Performance Insights

To access Performance Insights, you must have the appropriate permissions from AWS Identity and Access Management (IAM). There are two options available for granting access:

1. Attach the `AmazonRDSFullAccess` managed policy to an IAM user or role.
2. Create a custom IAM policy and attach it to an IAM user or role.

AmazonRDSFullAccess managed policy

AmazonRDSFullAccess is an AWS-managed policy that grants access to all of the Amazon RDS API operations. The policy also grants access to related services that are used by the Amazon RDS console—for example, event notifications using Amazon SNS.

In addition, AmazonRDSFullAccess contains all the permissions needed for using Performance Insights. If you attach this policy to an IAM user or role, the recipient can use Performance Insights, along with other console features.

Using a custom IAM policy

For users who don't have full access with the AmazonRDSFullAccess policy, you can grant access to Performance Insights by creating or modifying a user-managed IAM policy. When you attach the policy to an IAM user or role, the recipient can use Performance Insights.

To create a custom policy

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Policies**.
3. Choose **Create policy**.
4. On the **Create Policy** page, choose the JSON tab.
5. Copy and paste the following.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "pi:*",  
            "Resource": "arn:aws:pi:*:metrics/rds/*"  
        }  
    ]  
}
```

6. Choose **Review policy**.
7. Provide a name for the policy and optionally a description, and then choose **Create policy**.

You can now attach the policy to an IAM user or role. The following procedure assumes that you already have an IAM user available for this purpose.

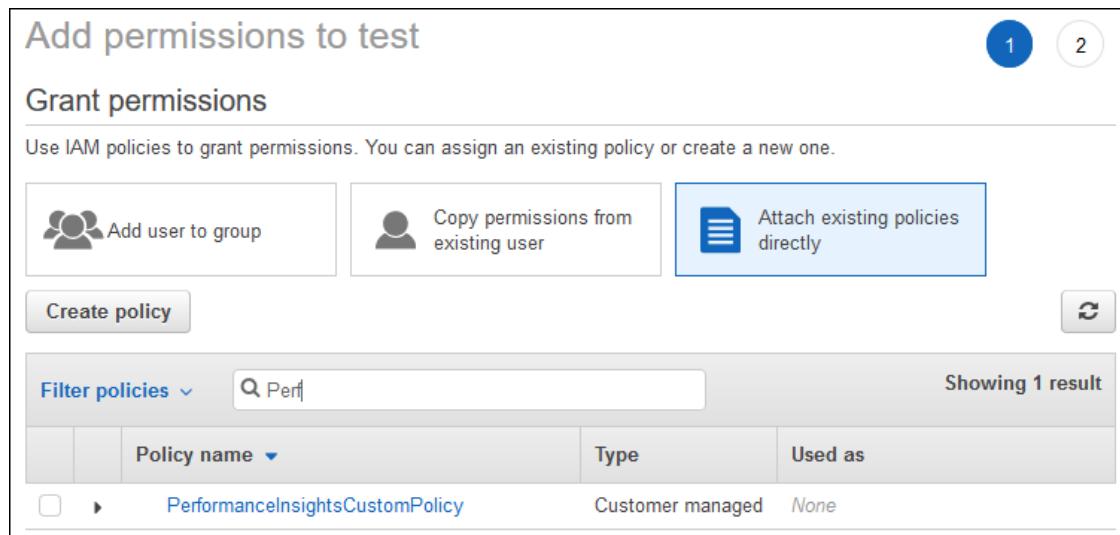

To attach the policy to an IAM user

1. Open the IAM console at <https://console.aws.amazon.com/iam/>.
2. In the navigation pane, choose **Users**.
3. Choose an existing user from the list.

Important

To use Performance Insights, make sure that you have access to Amazon RDS in addition to the custom policy. For example, the AmazonRDSReadOnlyAccess predefined policy provides read-only access to Amazon RDS. For more information, see [Managing access using policies \(p. 1646\)](#).

4. On the **Summary** page, choose **Add permissions**.
5. Choose **Attach existing policies directly**. For **Search**, type the first few characters of your policy name, as shown following.

6. Choose your policy, and then choose **Next: Review**.
7. Choose **Add permissions**.

Monitoring with the Performance Insights dashboard

The Performance Insights dashboard contains database performance information to help you analyze and troubleshoot performance issues. On the main dashboard page, you can view information about the database load. You can also drill into details for a particular wait state, SQL query, host, or user.

Opening the Performance Insights dashboard

To see the Performance Insights dashboard, use the following procedure.

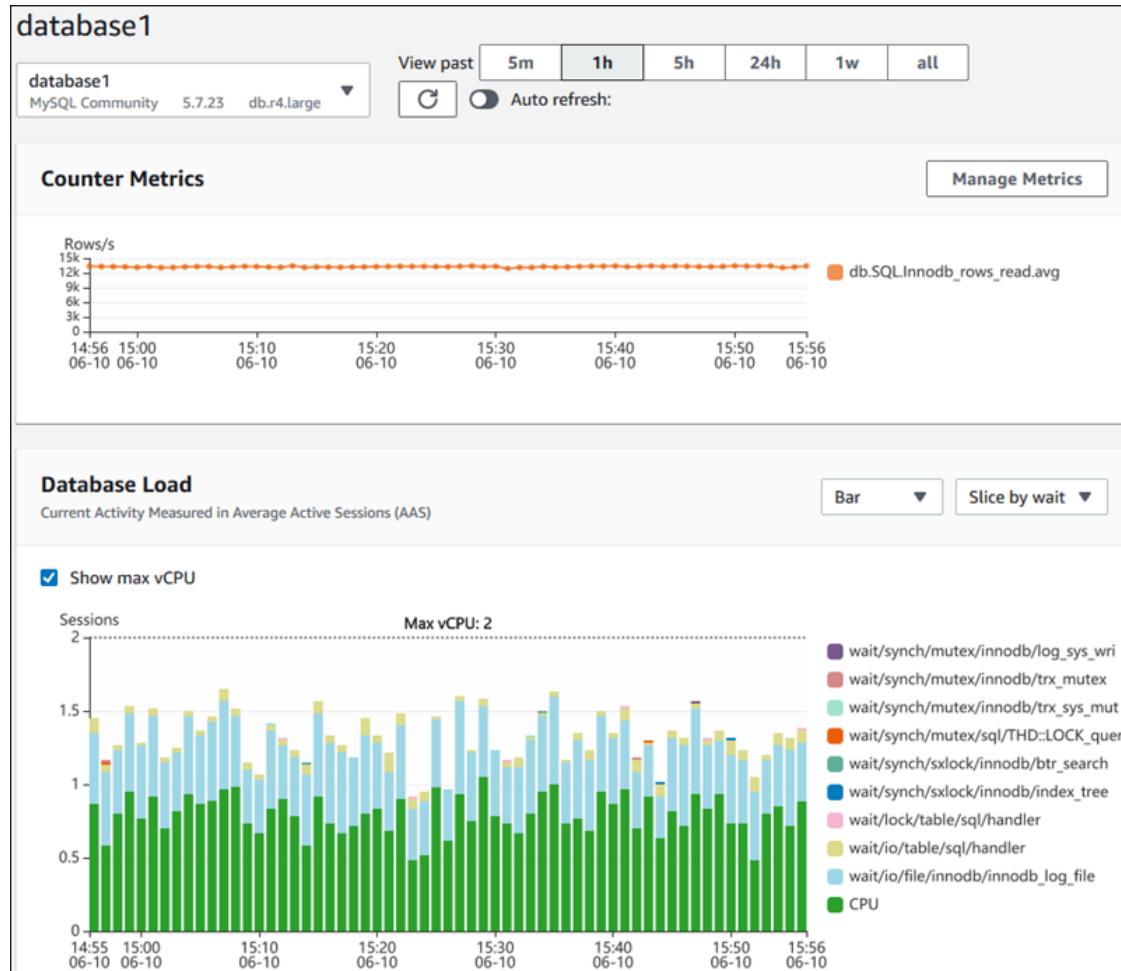

To view the Performance Insights dashboard in the AWS Management Console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is displayed for that DB instance.

For DB instances with Performance Insights enabled, you can also reach the dashboard by choosing the **Sessions** item in the list of DB instances. Under **Current activity**, the **Sessions** item shows the database load in average active sessions over the last five minutes. The bar graphically shows the load. When the bar is empty, the DB instance is idle. As the load increases, the bar fills with blue. When the load passes the number of virtual CPUs (vCPUs) on the DB instance class, the bar turns red, indicating a potential bottleneck.

Databases		<input checked="" type="radio"/> Group resources		Modify	Actions ▾	Restore from S3	Create database
<input type="text"/> Filter databases							
<input type="checkbox"/>	DB identifier		▲	Engine	▼	CPU	Current activity
<input type="checkbox"/>	database1			MySQL Community		<div style="width: 45.51%;">45.51%</div>	<div style="width: 1.34%;">1.34 Sessions</div>
<input type="checkbox"/>	database2			Oracle Enterprise Edition		<div style="width: 55.41%;">55.41%</div>	<div style="width: 3.48%;">3.48 Sessions</div>
<input type="checkbox"/>	database3			Oracle Enterprise Edition		<div style="width: 1.02%;">1.02%</div>	<div style="width: 0%;">0 Connections</div>

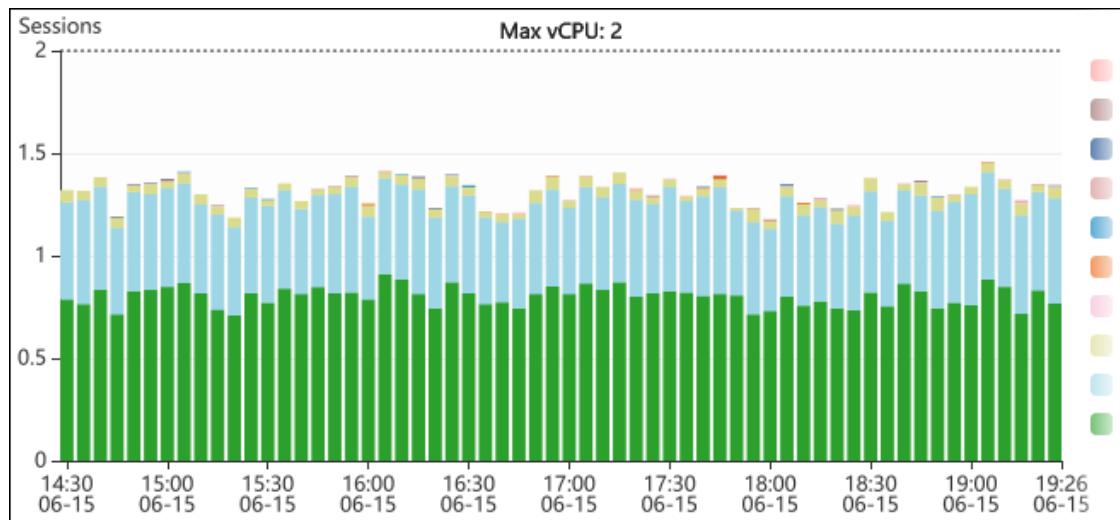

The following screenshot shows the dashboard for a DB instance. By default, the Performance Insights dashboard shows data for the last hour.

4. (Optional) Choose a different time interval by selecting a button in the upper right. For example, to change the interval to 5 hours, select **5h**.

In the following screenshot, the DB load interval is 5 hours.

5. (Optional) To refresh your data automatically, enable **Auto refresh**.

The Performance Insight dashboard automatically refreshes with new data. The refresh rate depends on the amount of data displayed:

- 5 minutes refreshes every 5 seconds.
- 1 hour refreshes every minute.
- 5 hours refreshes every minute.
- 24 hours refreshes every 5 minutes.
- 1 week refreshes every hour.

Performance Insights dashboard components

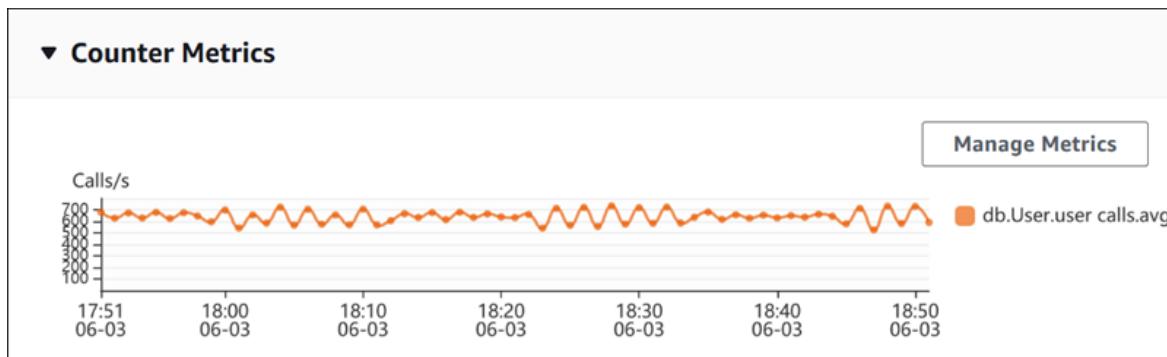

The dashboard is divided into three parts:

1. **Counter Metrics** – Shows data for specific performance counter metrics.
2. **DB Load Chart** – Shows how the DB load compares to DB instance capacity as represented by the **Max vCPU** line.
3. **Top items** – Shows the top waits, SQL, hosts, and users contributing to DB load.

Counter Metrics chart

The **Counter Metrics** chart displays data for performance counters. The default metrics depend on the DB engine.

- MySQL and MariaDB – db.SQL.Innodb_rows_read.avg
- Oracle – db.User.user_calls.avg
- Microsoft SQL Server – db.Databases.Active_Transactions(_Total).avg
- PostgreSQL – db.Transactions.xact_commit.avg

Change the performance counters by choosing **Manage Metrics**. You can select multiple **OS metrics** or **Database metrics**, as shown in the following screenshot. To see details for any metric, hover over the metric name.

This screenshot shows the 'Select metrics shown on the graph' dialog box. It includes a search bar labeled 'Find metrics', a tab for 'Database metrics (1)' which is selected, and a 'Clear all selections' button. The main area lists various metrics grouped by category:

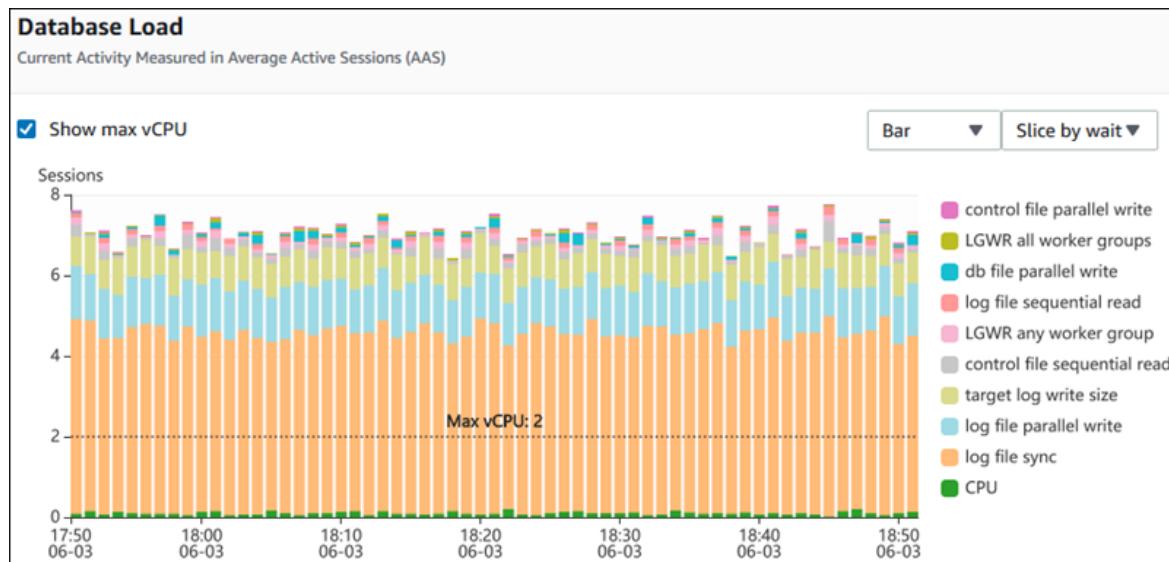

- User**:
 - CPU used by this session
 - user commits
 - bytes sent via SQL*Net to client
 - SQL*Net roundtrips to/from client
 - logons cumulative
 - user calls
 - bytes received via SQL*Net from client
 - user rollbacks
- Redo**:
 - redo size
- Cache**:
 - physical read bytes
 - physical reads
 - consistent gets
 - db block gets
 - consistent gets from cache
 - DBWR checkpoints
 - db block gets from cache
- SQL**:
 - parse count (total)
 - sorts (memory)
 - parse count (hard)
 - sorts (disk)
 - table scan rows gotten
 - sorts (rows)

At the bottom right are 'Cancel' and 'Update graph' buttons.

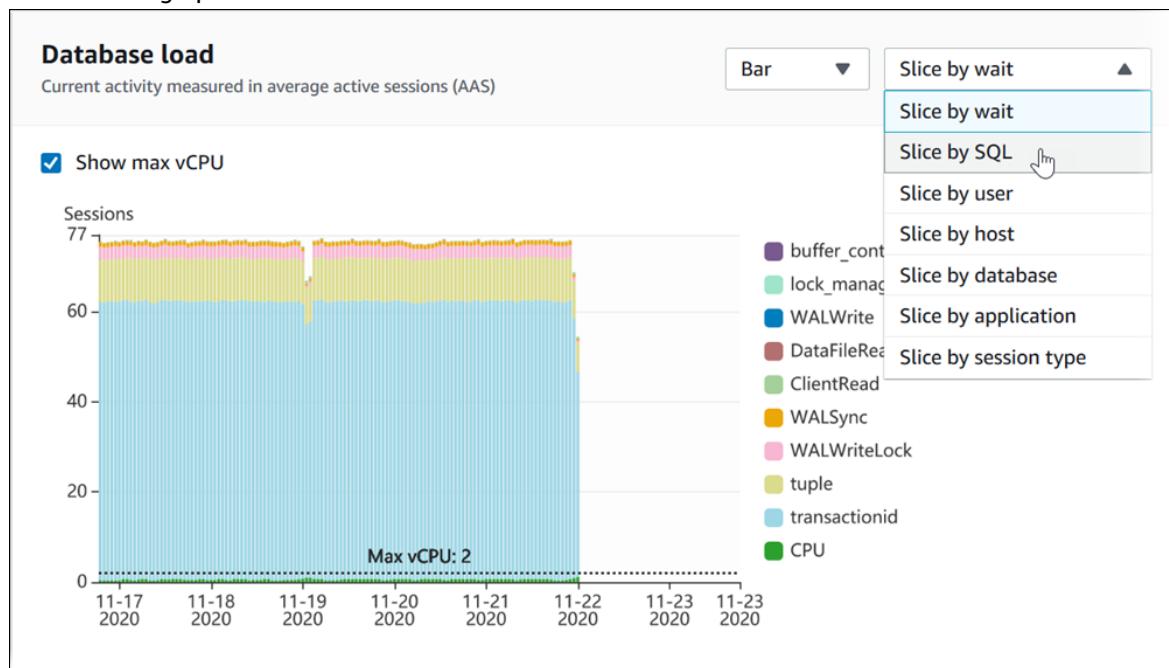

For more information, see [Customizing the Performance Insights dashboard \(p. 444\)](#).

Average Active Sessions chart

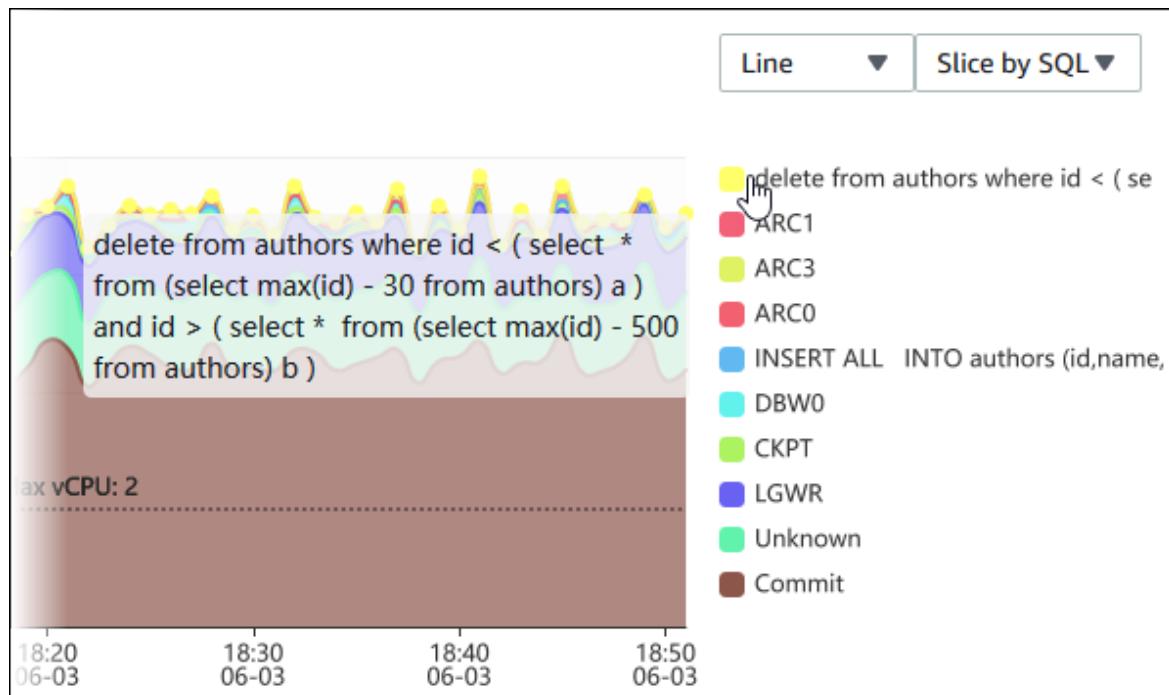

The **Database Load** chart shows how the database load compares to DB instance capacity as represented by the **Max vCPU** line. By default, load is shown as active sessions grouped by wait states in a bar graph.

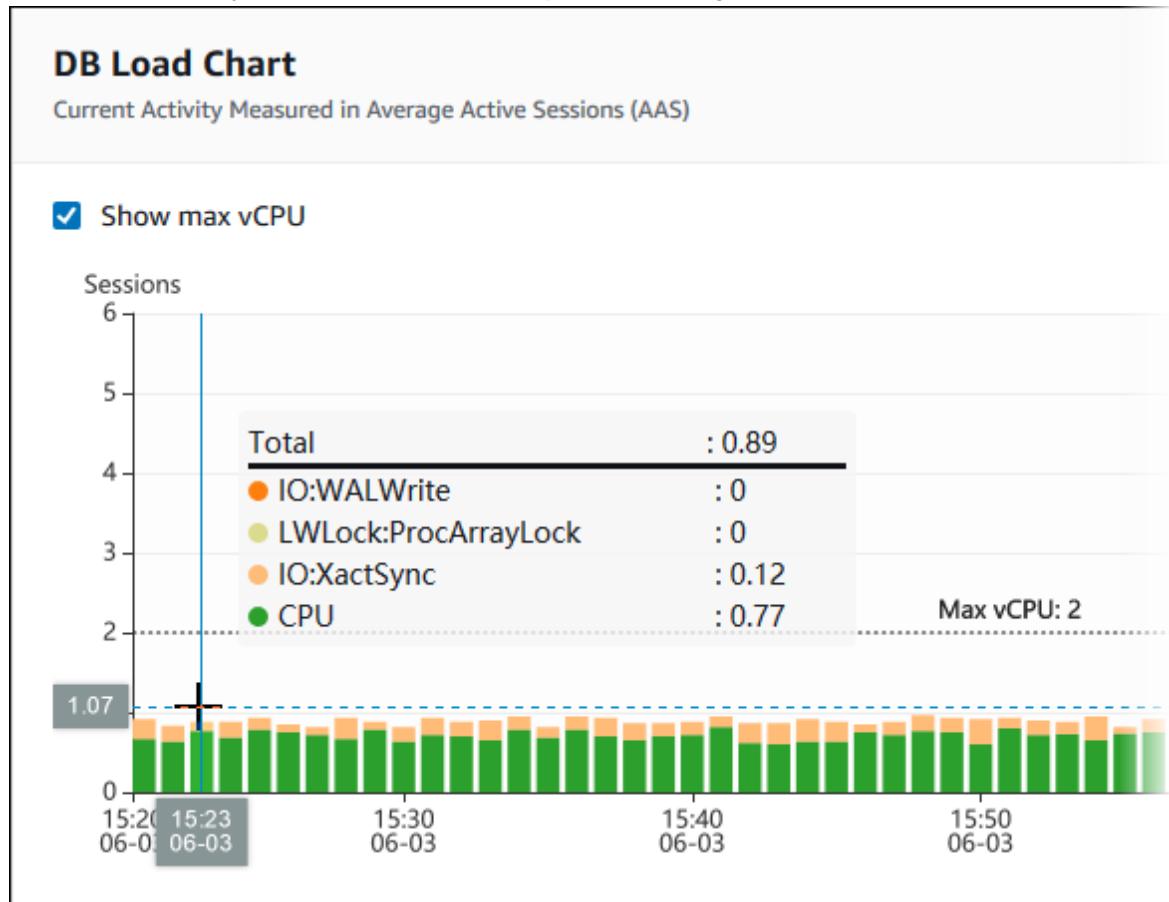

You can choose to display load as active sessions grouped by waits, SQL, users, or hosts. You can also choose a line graph.

To see details about a DB load item such as a SQL statement, hover over the item name.

To see details for any item for the selected time period in the legend, hover over that item.

Top load table

The Top load table shows the top items contributing to database load. You can choose any of the following dimension tabs:

- Top SQL – The SQL statements that are currently running
- Top waits – The event for which the database backend is waiting
- Top hosts – The host name of the connected client
- Top users – The user logged in to the database
- Top databases – The name of the database to which the client is connected (PostgreSQL, MySQL, and MariaDB only)
- Top applications (PostgreSQL only) – The name of the application that is connected to the database
- Top session types (PostgreSQL only) – The type of the current session

By default, the console displays top SQL queries that are contributing to the database load. Every line in the table shows relevant statistics for the SQL statement:

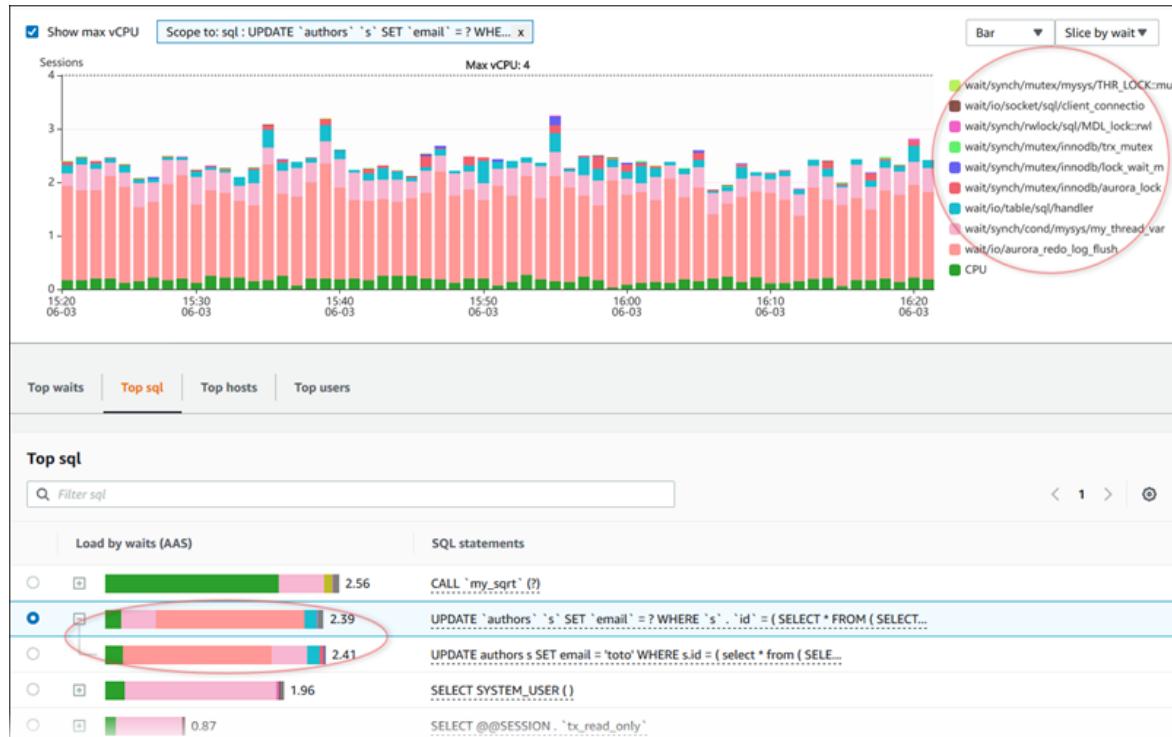

Top SQL			
<input type="text"/> Filter sql			
Load by waits (AAS)	SQL statements	calls/sec	rows/sec
0.88	select minute_rollups(?)	0.06	0.06
0.53	select count(*) from authors where id < (select max(id) - 31 from authors) and...	33.68	101.04
0.17	WITH cte AS (SELECT id FROM authors LIMIT ?) UPDATE ...	33.68	33.68
0.08	delete from authors where id < (select * from (select max(id) - ? from authors...)	33.68	303.13
0.07	INSERT INTO authors (id,name,email) VALUES (nextval(?) ,? , (nextval(?) ,?))	33.68	303.13
0.06	select count(*) from authors where id < (select max(id) - 31 from authors) and...	0.00	0.00

To see the components of a query, select the query, and then choose the +. A *SQL digest* is a composite of multiple actual queries that are structurally similar but that possibly have different literal values. In the following screenshot, the selected query is a digest. The digest replaces hardcoded values with a question mark.

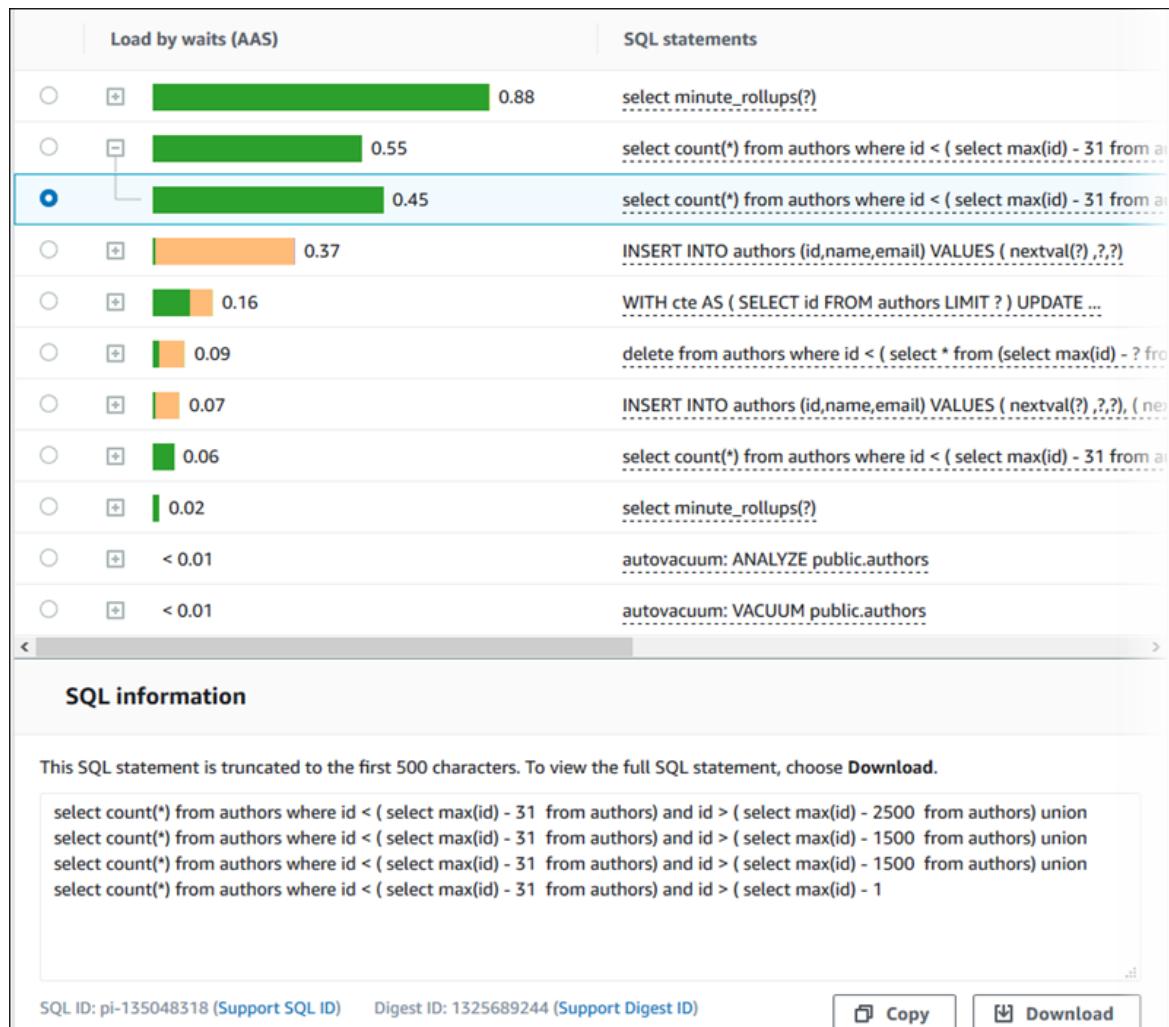

Note

A SQL digest groups similar SQL statements, but does not redact sensitive information.

In **Top sql**, the **Load by waits (AAS)** column illustrates the percentage of the database load associated with each top load item. This column reflects the load for that item by whatever grouping is currently selected in the **DB Load Chart**. For example, you might group the **DB Load Chart** chart by wait states. You examine SQL queries in the top load items table. In this case, the **DB Load by Waits** bar is sized, segmented, and color-coded to show how much of a given wait state that query is contributing to. It also shows which wait states are affecting the selected query.

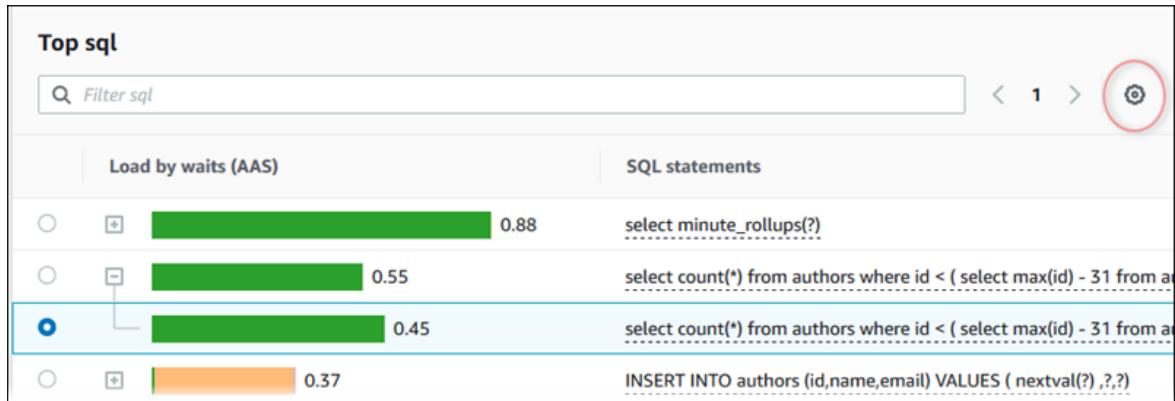

In the **Top sql** table, you can open a statement to view its information. The information appears in the bottom pane.

In the **Top sql** tab, you can view the following types of identifiers (IDs) that are associated with SQL statements:

- **Support SQL ID** – A hash value of the SQL ID. This value is only for referencing a SQL ID when you are working with AWS Support. AWS Support doesn't have access to your actual SQL IDs and SQL text.
- **Support Digest ID** – A hash value of the digest ID. This value is only for referencing a digest ID when you are working with AWS Support. AWS Support doesn't have access to your actual digest IDs and SQL text.

You can control the statistics displayed in the **Top sql** tab by choosing the **Preferences** icon.

When you choose the **Preferences** icon, the **Preferences** window opens.

The Preferences window allows you to set page size and column visibility. The 'All resources' option is selected under 'Page size'. Under 'Columns', most metrics are enabled (indicated by blue switches), except for 'local blk dirty/sec (local_blk_dirtied_per_sec)' which is disabled (gray switch).

Column	Status
Load by waits (AAS)	Enabled
SQL statements	Enabled
calls/sec (calls_per_sec)	Enabled
rows/sec (rows_per_sec)	Enabled
AAE (total_time_per_sec)	Enabled
blk hits/sec (shared_blk_hit_per_sec)	Enabled
blk reads/sec (shared_blk_read_per_sec)	Enabled
blk dirty/sec (shared_blk_dirtied_per_sec)	Enabled
blk writes/sec (shared_blk_written_per_sec)	Enabled
local blk hits/sec (local_blk_hit_per_sec)	Enabled
local blk reads/sec (local_blk_read_per_sec)	Enabled
local blk dirty/sec (local_blk_dirtied_per_sec)	Disabled

Enable the statistics that you want to have visible in the **Top sql** tab, use your mouse to scroll to the bottom of the window, and then choose **Continue**.

Analyzing DB load using the Performance Insights dashboard

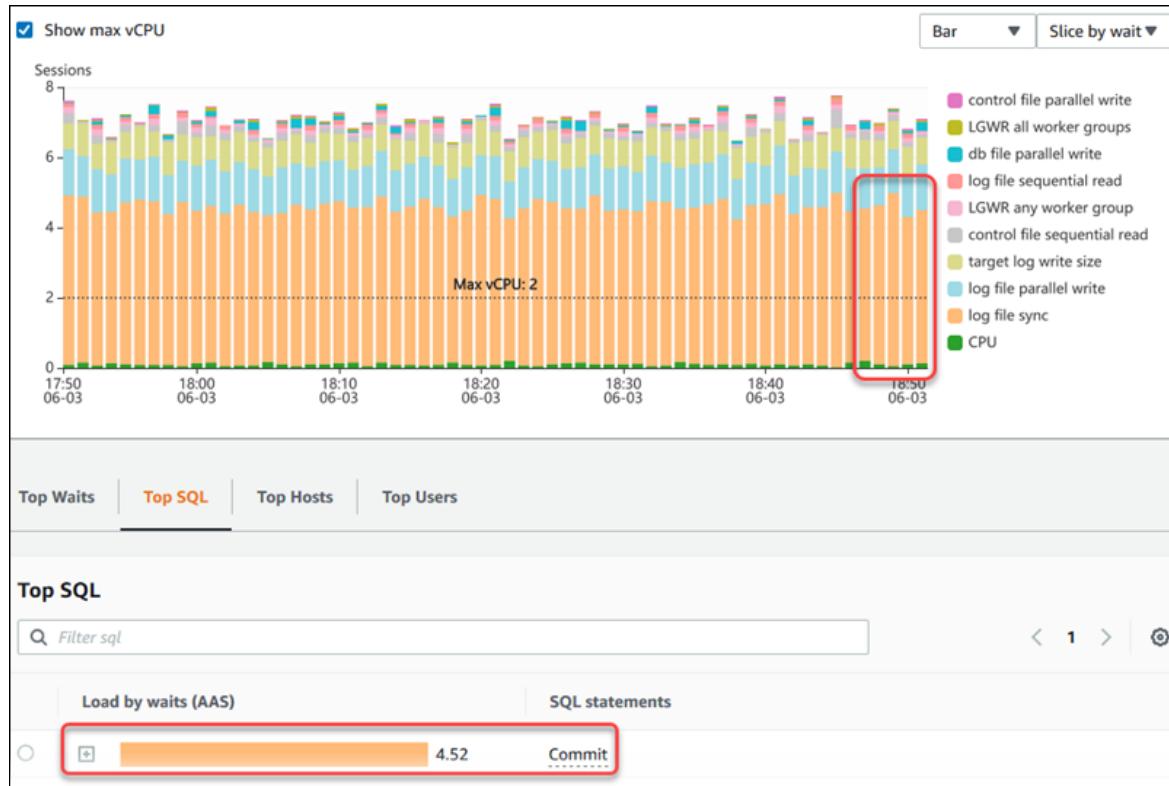

If the **Average Active Sessions** chart shows a bottleneck, you can find out where the load is coming from. To do so, look at the top load items table below the **Average Active Sessions** chart. Choose a particular item, like a SQL query or a user, to drill down into that item and see details about it.

DB load grouped by waits and top SQL queries is the default Performance Insights dashboard view. This combination typically provides the most insight into performance issues. DB load grouped by waits shows if there are any resource or concurrency bottlenecks in the database. In this case, the **SQL** tab of the top load items table shows which queries are driving that load.

Your typical workflow for diagnosing performance issues is as follows:

1. Review the **Average Active Sessions** chart and see if there are any incidents of database load exceeding the **Max CPU** line.
2. If there is, look at the **Average Active Sessions** chart and identify which wait state or states are primarily responsible.
3. Identify the digest queries causing the load by seeing which of the queries the **SQL** tab on the top load items table are contributing most to those wait states. You can identify these by the **DB Load by Wait** column.
4. Choose one of these digest queries in the **SQL** tab to expand it and see the child queries that it is composed of.

For example, in the dashboard following, **log file sync** waits account for most of the DB load. The **LGWR all worker groups** wait is also high. The **Top sql** chart shows what is causing the **log file sync** waits: frequent COMMIT statements. In this case, committing less frequently will reduce DB load.

Analyzing statistics for running queries

In Amazon RDS Performance Insights, you can find statistics on running queries in the **Top SQL** section. Performance Insights collects statistics only for the most common queries. Typically, these match the top queries by load shown in the Performance Insights dashboard.

Topics

- [Statistics for MariaDB and MySQL \(p. 432\)](#)
- [Statistics for Oracle \(p. 435\)](#)
- [Statistics for PostgreSQL \(p. 438\)](#)

Statistics for MariaDB and MySQL

Performance Insights collects SQL digest statistics from the `events_statements_summary_by_digest` table. This table is managed by the database and doesn't have an eviction policy. If the table becomes full, new SQL queries aren't tracked. To address this issue, Performance Insights automatically truncates the table when it's nearly full.

Performance Insights automatically truncates the table only if your parameter group doesn't have an explicitly set value for the `performance_schema` parameter. You can examine the `performance_schema` parameter, and if the value of source is `user`, then you set a value. If you want Performance Insights to truncate the table automatically, then reset the value for the `performance_schema` parameter. You can view the source of a parameter value by viewing the parameter in the AWS Management Console or by running the AWS CLI [describe-db-parameters](#) command. The following message is shown in the AWS Management Console when the table is full:

Performance Insights is unable to collect SQL Digest statistics on new queries because the table `events_statements_summary_by_digest` is full.
Please truncate `events_statements_summary_by_digest` table to clear the issue. Check the User Guide for more details.

The following SQL statistics are available for MariaDB and MySQL DB instances.

Metric	Unit
<code>db.sql_tokenized.stats.count_star_per_sec</code>	Calls per second
<code>db.sql_tokenized.stats.sum_timer_wait_per_sec</code>	Average active executions per second (AAE)
<code>db.sql_tokenized.stats.sum_select_full_join_per_sec</code>	Select full join per second
<code>db.sql_tokenized.stats.sum_select_range_check_per_sec</code>	Select range check per second
<code>db.sql_tokenized.stats.sum_select_scan_per_sec</code>	Select scan per second
<code>db.sql_tokenized.stats.sum_sort_merge_passes_per_sec</code>	Sort merge passes per second
<code>db.sql_tokenized.stats.sum_sort_scan_per_sec</code>	Sort scans per second
<code>db.sql_tokenized.stats.sum_sort_range_per_sec</code>	Sort ranges per second
<code>db.sql_tokenized.stats.sum_sort_rows_per_sec</code>	Sort rows per second
<code>db.sql_tokenized.stats.sum_rows_affected_per_sec</code>	Rows affected per second
<code>db.sql_tokenized.stats.sum_rows_examined_per_sec</code>	Rows examined per second

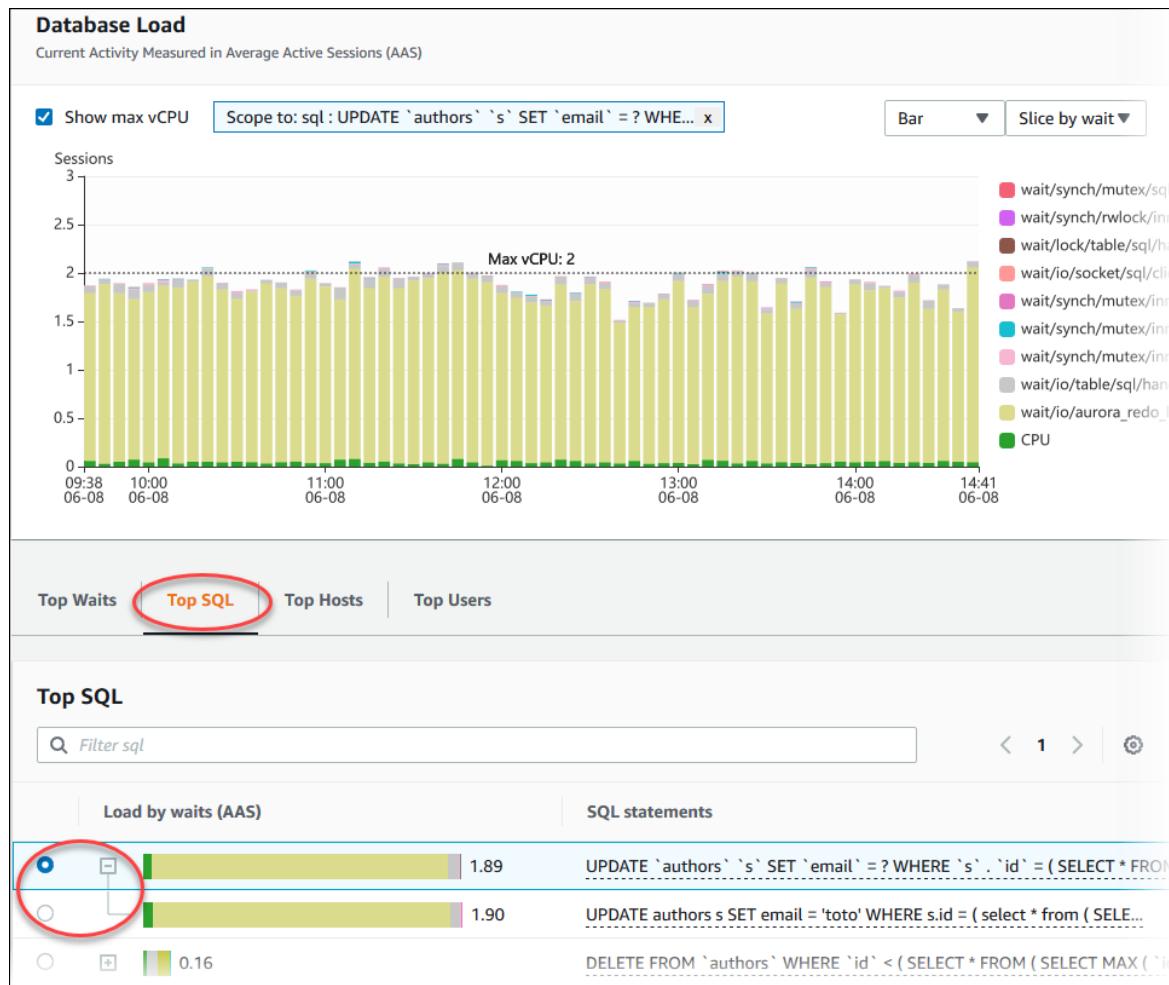

Metric	Unit
db.sql_tokenized.stats.sum_rows_sent_per_sec	Rows sent per second
db.sql_tokenized.stats.sum_created_tmp_disk_tables	Created temporary disk tables per second
db.sql_tokenized.stats.sum_created_tmp_tables_per_sec	Created temporary tables per second
db.sql_tokenized.stats.sum_lock_time_per_sec	Lock time per second (in ms)

The following metrics provide per call statistics for a SQL statement.

Metric	Unit
db.sql_tokenized.stats.sum_timer_wait_per_call	Average latency per call (in ms)
db.sql_tokenized.stats.sum_select_full_join_per_call	Select full joins per call
db.sql_tokenized.stats.sum_select_range_check_per_call	Select range check per call
db.sql_tokenized.stats.sum_select_scan_per_call	Select scans per call
db.sql_tokenized.stats.sum_sort_merge_passes_per_call	Sort merge passes per call
db.sql_tokenized.stats.sum_sort_scan_per_call	Sort scans per call
db.sql_tokenized.stats.sum_sort_range_per_call	Sort ranges per call
db.sql_tokenized.stats.sum_sort_rows_per_call	Sort rows per call
db.sql_tokenized.stats.sum_rows_affected_per_call	Rows affected per call
db.sql_tokenized.stats.sum_rows_examined_per_call	Rows examined per call
db.sql_tokenized.stats.sum_rows_sent_per_call	Rows sent per call
db.sql_tokenized.stats.sum_created_tmp_disk_tables	Created temporary disk tables per call
db.sql_tokenized.stats.sum_created_tmp_tables_per_call	Created temporary tables per call
db.sql_tokenized.stats.sum_lock_time_per_call	Lock time per call (in ms)

Analyzing MariaDB and MySQL Metrics for running SQL statements

Using the AWS Management Console, you can view the metrics for a running SQL query by choosing the **SQL** tab and expanding the query.

Choose which statistics to display by choosing the gear icon in the upper-right corner of the chart.

The following screenshot shows the preferences for MariaDB and MySQL DB instances.

Preferences

Statistics for PostgreSQL

To view SQL Digest statistics, the `pg_stat_statements` library must be loaded. For PostgreSQL DB instances that are compatible with PostgreSQL 11 or later, this library is loaded by default. For PostgreSQL DB instances that are compatible with PostgreSQL 10 or earlier, you enable this library manually. To enable it manually, add `pg_stat_statements` to `shared_preload_libraries` in the DB parameter group associated with the DB instance. Then reboot your DB instance. For more information, see [Working with DB parameter groups \(p. 228\)](#).

Note

Performance Insights can only collect statistics for queries in `pg_stat_activity` that aren't truncated. By default, PostgreSQL databases truncate queries longer than 1,024 bytes. To increase the query size, change the `track_activity_query_size` parameter in the DB parameter group associated with your DB instance. When you change this parameter, a DB instance reboot is required.

The following SQL Digest statistics are available for PostgreSQL DB instances.

Metric	Unit
<code>db.sql_tokenized.stats.calls_per_sec</code>	Calls per second
<code>db.sql_tokenized.stats.rows_per_sec</code>	Rows per second
<code>db.sql_tokenized.stats.total_time_per_sec</code>	Average active executions per second (AAE)
<code>db.sql_tokenized.stats.shared_blk_hit_per_sec</code>	Block hits per second
<code>db.sql_tokenized.stats.shared_blk_read_per_sec</code>	Block reads per second
<code>db.sql_tokenized.stats.shared_blk_dirtied_per_sec</code>	Blocks dirtied per second
<code>db.sql_tokenized.stats.shared_blk_written_per_sec</code>	Block writes per second
<code>db.sql_tokenized.stats.local_blk_hit_per_sec</code>	Local block hits per second
<code>db.sql_tokenized.stats.local_blk_read_per_sec</code>	Local block reads per second
<code>db.sql_tokenized.stats.local_blk_dirtied_per_sec</code>	Local block dirty per second
<code>db.sql_tokenized.stats.local_blk_written_per_sec</code>	Local block writes per second
<code>db.sql_tokenized.stats.temp_blk_written_per_sec</code>	Temporary writes per second
<code>db.sql_tokenized.stats.temp_blk_read_per_sec</code>	Temporary reads per second
<code>db.sql_tokenized.stats.blk_read_time_per_sec</code>	Average concurrent reads per second
<code>db.sql_tokenized.stats.blk_write_time_per_sec</code>	Average concurrent writes per second

The following metrics provide per call statistics for a SQL statement.

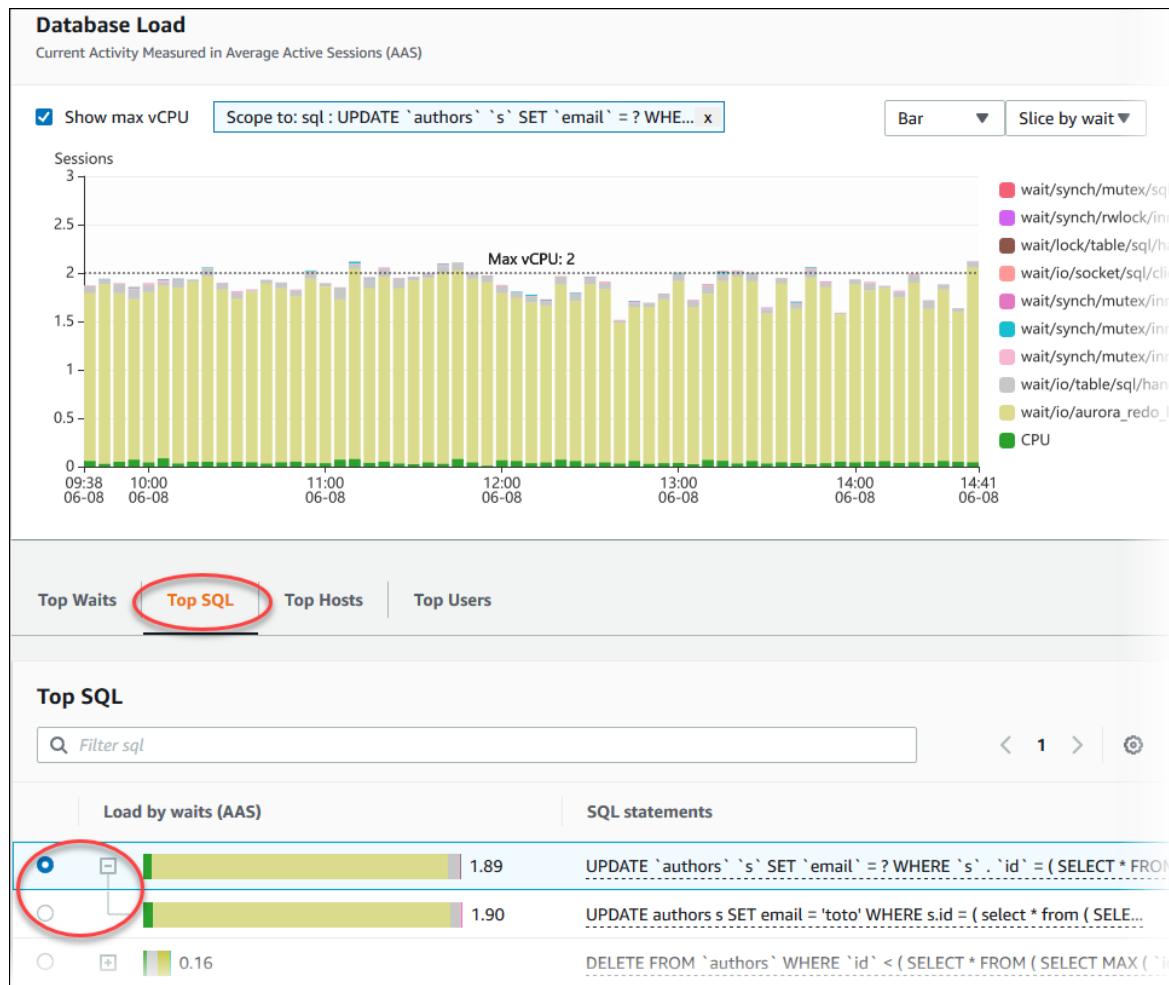

Metric	Unit
<code>db.sql_tokenized.stats.rows_per_call</code>	Rows per call
<code>db.sql_tokenized.stats.avg_latency_per_call</code>	Average latency per call (in ms)
<code>db.sql_tokenized.stats.shared_blk_hit_per_call</code>	Block hits per call

Metric	Unit
db.sql_tokenized.stats.shared_blk_reads_per_call	Block reads per call
db.sql_tokenized.stats.shared_blk_writes_per_call	Block writes per call
db.sql_tokenized.stats.shared_blk_dirtied_per_call	Blocks dirtied per call
db.sql_tokenized.stats.local_blk_hits_per_call	Local block hits per call
db.sql_tokenized.stats.local_blk_reads_per_call	Local block reads per call
db.sql_tokenized.stats.local_blk_dirtied_per_call	Local block dirty per call
db.sql_tokenized.stats.local_blk_writes_per_call	Local block writes per call
db.sql_tokenized.stats.temp_blk_writes_per_call	Temporary block writes per call
db.sql_tokenized.stats.temp_blk_reads_per_call	Temporary block reads per call
db.sql_tokenized.stats.blk_read_time_per_call	Read time per call (in ms)
db.sql_tokenized.stats.blk_write_time_per_call	Write time per call (in ms)

For more information about these metrics, see [pg_stat_statements](#) in the PostgreSQL documentation.

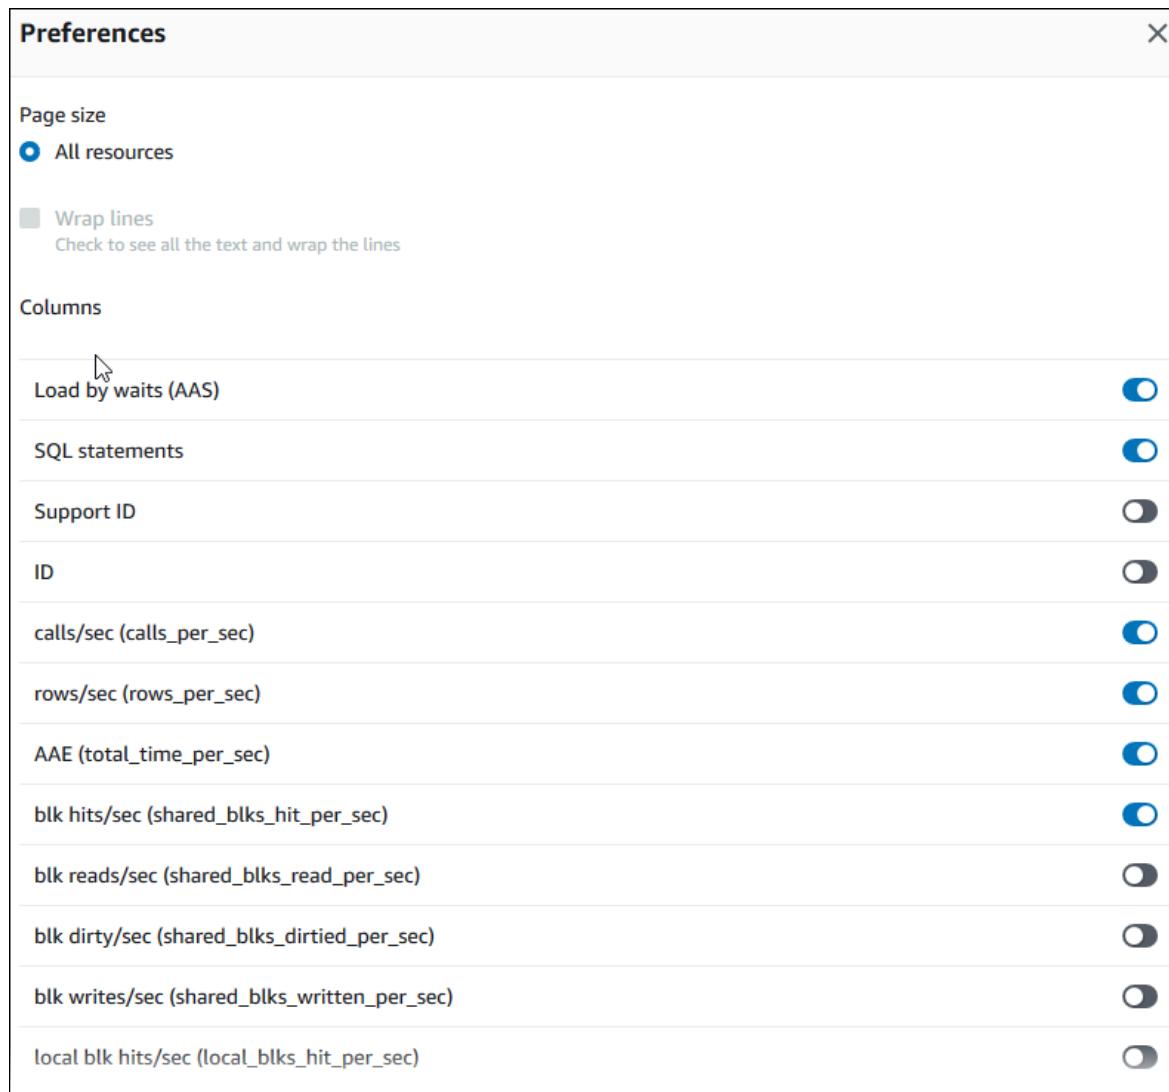

Analyzing PostgreSQL metrics for running SQL statements

Using the AWS Management Console, you can view the metrics for a running SQL query by choosing the **SQL** tab.

Choose which statistics to display by choosing the gear icon in the upper-right corner of the chart.

The following screenshot shows the preferences for PostgreSQL.

Viewing more SQL text in the Performance Insights dashboard

By default, each row in the **Top sql** table shows 500 bytes of SQL text for each SQL statement. When a SQL statement is larger than 500 bytes, you can view more of the SQL statement by opening the statement in the Performance Insights dashboard. The dashboard displays text up to the following per-engine limits:

- Amazon RDS for Microsoft SQL Server – 4,096 characters
- Amazon RDS for MySQL and MariaDB – 1,024 bytes
- Amazon RDS for Oracle – 1,000 bytes

You can copy the text that is displayed on the dashboard. If you view a child SQL statement, you can also choose **Download**.

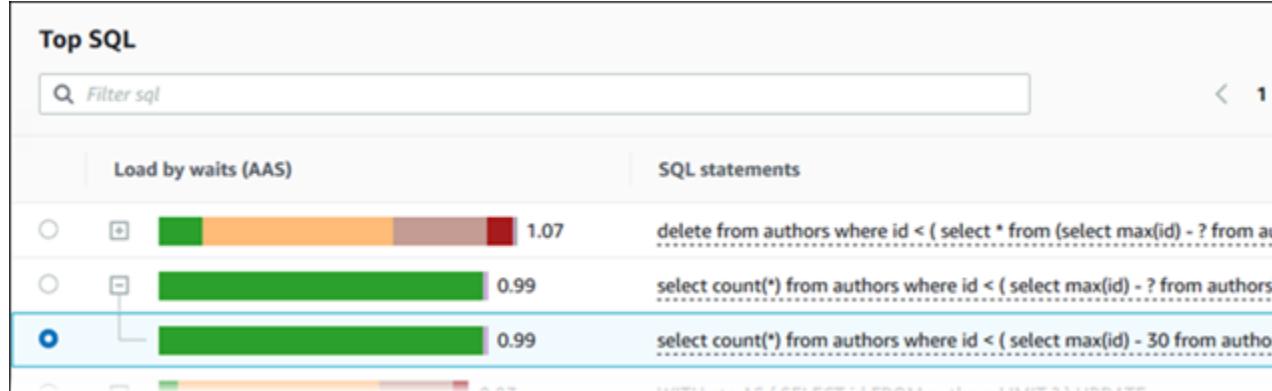

Amazon RDS for PostgreSQL handles text differently. Using the Performance Insights dashboard, you can view and download up to 500 bytes. To access more than 500 bytes, set the size limit with the DB instance parameter `track_activity_query_size`. The maximum value is 102,400 bytes. To view

or download text over 500 bytes, use the AWS Management Console, not the Performance Insights CLI or API. For more information, see [Setting the SQL text limit for Amazon RDS for PostgreSQL DB instances \(p. 442\)](#).

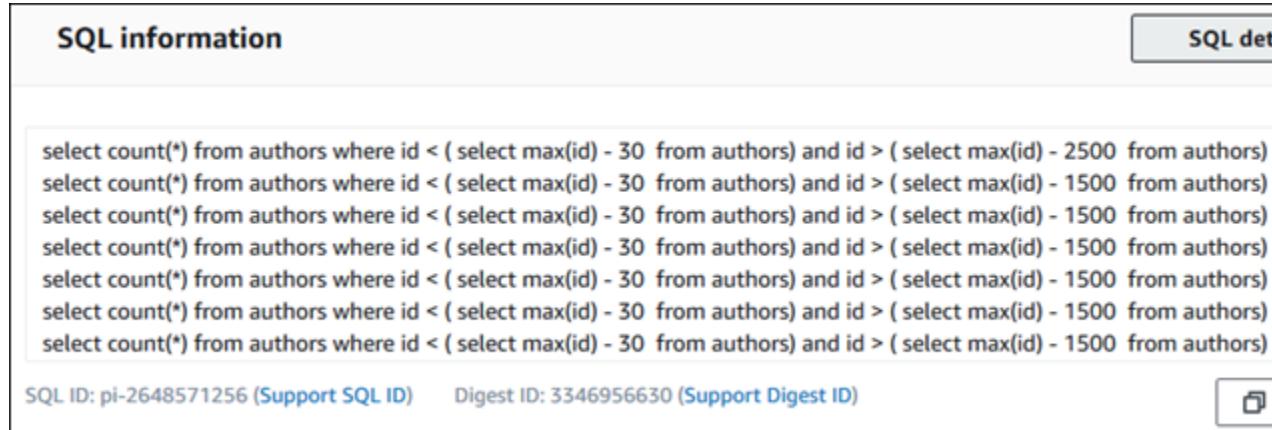

To view more SQL text in the Performance Insights dashboard

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Performance Insights**.
3. Choose a DB instance. The Performance Insights dashboard is displayed for that DB instance.

SQL statements with text larger than 500 bytes look similar to the following image.

4. Examine the SQL information section to view more of the SQL text.

The Performance Insights dashboard can display up to 4,096 bytes for each SQL statement.

5. (Optional) Choose **Copy** to copy the displayed SQL statement, or choose **Download** to download the SQL statement to view the SQL text up to the DB engine limit.

Note

To copy or download the SQL statement, disable pop-up blockers.

Setting the SQL text limit for Amazon RDS for PostgreSQL DB instances

For Amazon RDS for PostgreSQL DB instances, you can control the limit for the SQL text that can be shown on the Performance Insights dashboard.

To do so, modify the `track_activity_query_size` DB instance parameter. The default setting for the `track_activity_query_size` parameter is 1,024 bytes.

You can increase the number of bytes to increase the SQL text size visible in the Performance Insights dashboard. The limit for the parameter is 102,400 bytes. For more information about the `track_activity_query_size` DB instance parameter, see [Run-time Statistics](#) in the PostgreSQL documentation.

To modify the parameter, change the parameter setting in the parameter group that is associated with the Amazon RDS for PostgreSQL DB instance.

If the Amazon RDS for PostgreSQL DB instance is using the default parameter group, complete the following steps:

1. Create a new DB instance parameter group for the appropriate DB engine and DB engine version.
2. Set the parameter in the new parameter group.
3. Associate the new parameter group with the DB instance.

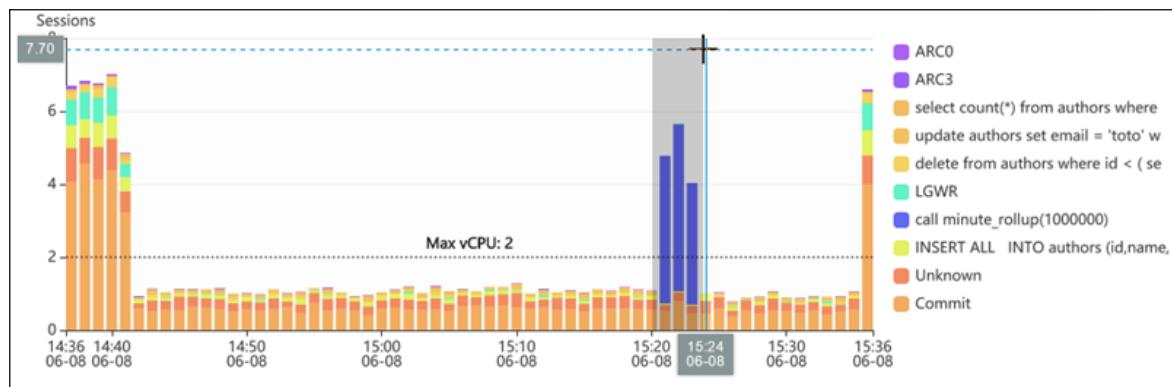

For information about setting a DB instance parameter, see [Modifying parameters in a DB parameter group \(p. 232\)](#).

Zooming In on the DB Load chart

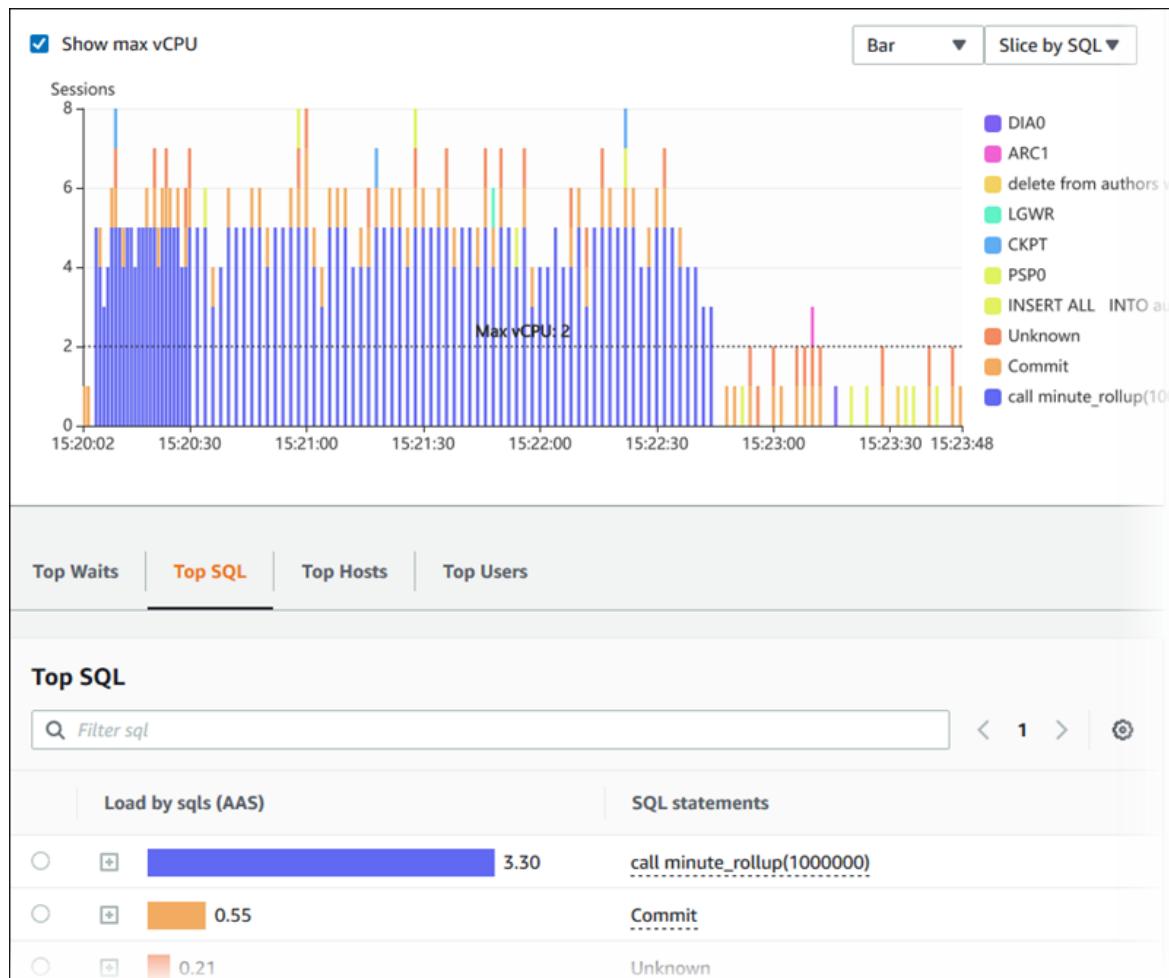

You can use other features of the Performance Insights user interface to help analyze performance data.

Click-and-Drag Zoom In

In the Performance Insights interface, you can choose a small portion of the load chart and zoom in on the detail.

To zoom in on a portion of the load chart, choose the start time and drag to the end of the time period you want. When you do this, the selected area is highlighted. When you release the mouse, the load chart zooms in on the selected AWS Region, and the **Top items** table is recalculated.

Customizing the Performance Insights dashboard

With counter metrics, you can customize the Performance Insights dashboard to include up to 10 additional graphs. These graphs that show a selection of dozens of operating system and database performance metrics. This information can be correlated with database load to help identify and analyze performance problems.

Performance Insights operating system counters

The following operating system counters are available with Performance Insights for Aurora PostgreSQL. You can find definitions for these metrics in [Viewing Enhanced Monitoring by using CloudWatch Logs \(p. 478\)](#).

Counter	Type	Metric
active	memory	os.memory.active
buffers	memory	os.memory.buffers
cached	memory	os.memory.cached
dirty	memory	os.memory.dirty
free	memory	os.memory.free
hugePagesFree	memory	os.memory.hugePagesFree
hugePagesRsvd	memory	os.memory.hugePagesRsvd
hugePagesSize	memory	os.memory.hugePagesSize
hugePagesSurp	memory	os.memory.hugePagesSurp
hugePagesTotal	memory	os.memory.hugePagesTotal
inactive	memory	os.memory.inactive
mapped	memory	os.memory.mapped
pageTables	memory	os.memory.pageTables
slab	memory	os.memory.slab
total	memory	os.memory.total
writeback	memory	os.memory.writeback
guest	cpuUtilization	os.cpuUtilization.guest
idle	cpuUtilization	os.cpuUtilization.idle
irq	cpuUtilization	os.cpuUtilization.irq
nice	cpuUtilization	os.cpuUtilization.nice
steal	cpuUtilization	os.cpuUtilization.steal
system	cpuUtilization	os.cpuUtilization.system
total	cpuUtilization	os.cpuUtilization.total
user	cpuUtilization	os.cpuUtilization.user
wait	cpuUtilization	os.cpuUtilization.wait
avgQueueLen	diskIO	os.diskIO.avgQueueLen
avgReqSz	diskIO	os.diskIO.avgReqSz
await	diskIO	os.diskIO.await
readIOsPS	diskIO	os.diskIO.readIOsPS
readKb	diskIO	os.diskIO.readKb
readKbPS	diskIO	os.diskIO.readKbPS

Counter	Type	Metric
rrqmPS	diskIO	os.diskIO.rrqmPS
tps	diskIO	os.diskIO.tps
util	diskIO	os.diskIO.util
writelOsPS	diskIO	os.diskIO.writelOsPS
writeKb	diskIO	os.diskIO.writeKb
writeKbPS	diskIO	os.diskIO.writeKbPS
wrqmPS	diskIO	os.diskIO.wrqmPS
blocked	tasks	os.tasks.blocked
running	tasks	os.tasks.running
sleeping	tasks	os.tasks.sleeping
stopped	tasks	os.tasks.stopped
total	tasks	os.tasks.total
zombie	tasks	os.tasks.zombie
one	loadAverageMinute	os.loadAverageMinute.one
fifteen	loadAverageMinute	os.loadAverageMinute.fifteen
five	loadAverageMinute	os.loadAverageMinute.five
cached	swap	os.swap.cached
free	swap	os.swap.free
in	swap	os.swap.in
out	swap	os.swap.out
total	swap	os.swap.total
maxFiles	fileSys	os.fileSys.maxFiles
usedFiles	fileSys	os.fileSys.usedFiles
usedFilePercent	fileSys	os.fileSys.usedFilePercent
usedPercent	fileSys	os.fileSys.usedPercent
used	fileSys	os.fileSys.used
total	fileSys	os.fileSys.total
rx	network	os.network.rx
tx	network	os.network.tx
numVCPU	general	os.general.numVCPU

Performance Insights counters for Amazon RDS for MariaDB and MySQL

The following database counters are available with Performance Insights for Amazon RDS for MariaDB and MySQL.

Topics

- [Native counters for RDS for MariaDB and RDS for MySQL \(p. 447\)](#)
- [Non-native counters for Amazon RDS for MariaDB and MySQL \(p. 448\)](#)

Native counters for RDS for MariaDB and RDS for MySQL

For definitions of these native metrics, see [Server Status Variables](#) in the MySQL documentation.

Counter	Type	Unit	Metric
Com_analyze	SQL	Queries per second	db.SQL.Com_analyze
Com_optimize	SQL	Queries per second	db.SQL.Com_optimize
Com_select	SQL	Queries per second	db.SQL.Com_select
Connections	SQL	The number of connection attempts per minute (successful or not) to the MySQL server	db.SQL.Connections
Innodb_rows_deleted	SQL	Rows per second	db.SQL.Innodb_rows_deleted
Innodb_rows_inserted	SQL	Rows per second	db.SQL.Innodb_rows_inserted
Innodb_rows_read	SQL	Rows per second	db.SQL.Innodb_rows_read
Innodb_rows_updated	SQL	Rows per second	db.SQL.Innodb_rows_updated
Select_full_join	SQL	Queries per second	db.SQL.Select_full_join
Select_full_range_join	SQL	Queries per second	db.SQL.Select_full_range_join
Select_range	SQL	Queries per second	db.SQL.Select_range
Select_range_check	SQL	Queries per second	db.SQL.Select_range_check
Select_scan	SQL	Queries per second	db.SQL.Select_scan
Slow_queries	SQL	Queries per second	db.SQL.Slow_queries
Sort_merge_passes	SQL	Queries per second	db.SQL.Sort_merge_passes
Sort_range	SQL	Queries per second	db.SQL.Sort_range
Sort_rows	SQL	Queries per second	db.SQL.Sort_rows
Sort_scan	SQL	Queries per second	db.SQL.Sort_scan
Questions	SQL	Queries per second	db.SQL.Questions
Innodb_row_lock_time	Locks	Milliseconds (average)	db.Locks.Innodb_row_lock_time

Counter	Type	Unit	Metric
Table_locks_immediate	Locks	Requests per second	db.Locks.Table_locks_immediate
Table_locks_waited	Locks	Requests per second	db.Locks.Table_locks_waited
Aborted_clients	Users	Connections	db.Users.Aborted_clients
Aborted_connects	Users	Connections	db.Users.Aborted_connects
Threads_created	Users	Connections	db.Users.Threads_created
Threads_running	Users	Connections	db.Users.Threads_running
Innodb_data_writes	I/O	Operations per second	db.IO.Innodb_data_writes
Innodb_dblwr_writes	I/O	Operations per second	db.IO.Innodb_dblwr_writes
Innodb_log_write_requests	I/O	Operations per second	db.IO.Innodb_log_write_requests
Innodb_log_writes	I/O	Operations per second	db.IO.Innodb_log_writes
Innodb_pages_written	I/O	Pages per second	db.IO.Innodb_pages_written
Created_tmp_disk_tables	Temp	Tables per second	db.Temp.Created_tmp_disk_tables
Created_tmp_tables	Temp	Tables per second	db.Temp.Created_tmp_tables
Innodb_buffer_pool_pages_cached	Cache	Pages	db.Cache.Innodb_buffer_pool_pages_cached
Innodb_buffer_pool_pages_total	Cache	Pages	db.Cache.Innodb_buffer_pool_pages_total
Innodb_buffer_pool_read_requests	Cache	Pages per second	db.Cache.Innodb_buffer_pool_read_requests
Innodb_buffer_pool_reads	Cache	Pages per second	db.Cache.Innodb_buffer_pool_reads
Opened_tables	Cache	Tables	db.Cache.Opened_tables
Opened_table_definitions	Cache	Tables	db.Cache.Opened_table_definitions
Qcache_hits	Cache	Queries	db.Cache.Qcache_hits

Non-native counters for Amazon RDS for MariaDB and MySQL

Non-native counter metrics are counters defined by Amazon RDS. A non-native metric can be a metric that you get with a specific query. A non-native metric also can be a derived metric, where two or more native counters are used in calculations for ratios, hit rates, or latencies.

Counter	Type	Metric	Description	Definition
innodb_buffer_pool_hits		db.Cache.innodb_buffer_pool_hits	The number of reads that InnoDB could satisfy from the buffer pool.	innodb_buffer_pool_read_requests - innodb_buffer_pool_reads
innodb_buffer_pool_hit_rate		db.Cache.innodb_buffer_pool_hit_rate	The percentage of reads that InnoDB could satisfy from the buffer pool.	100 * innodb_buffer_pool_read_requests / (innodb_buffer_pool_read_requests + innodb_buffer_pool_reads)

Counter	Type	Metric	Description	Definition
innodb_buffer_pool_usage	Code	db.Cache.innodb_buffer_pool_usage	The percentage of the InnoDB buffer pool that contains data (pages). Note When using compressed tables, this value can vary. For more information, see the information about Innodb_buffer_pool_pages_data and Innodb_buffer_pool_pages_total in Server Status Variables in the MySQL documentation.	Innodb_buffer_pool_pages_data / Innodb_buffer_pool_pages_total * 100.0
query_cache_hits	Code	db.Cache.query_cache_hits	MySQL result set cache (query cache) hit ratio.	Qcache_hits / (QCache_hits + Com_select) * 100
innodb_datafile_writes_to_disk	Code	db.IO.innodb_datafile_writes_to_disk	The number of InnoDB data file writes to disk, excluding double write and redo logging write operations.	Innodb_data_writes - Innodb_log_writes - Innodb_dblwr_writes
innodb_rows_change	Code	db.SQL.innodb_rows_change	The total number of InnoDB row operations.	db.SQL.Innodb_rows_inserted + db.SQL.Innodb_rows_deleted + db.SQL.Innodb_rows_updated
active_transactions	Transactions	db.Transaction.active_transactions	The total number of active transactions.	SELECT COUNT(1) AS active_transactions FROM INFORMATION_SCHEMA.INNODB_TRX
innodb_deadlocks	Locks	db.Locks.innodb_deadlocks	The total number of deadlocks.	SELECT COUNT AS innodb_deadlocks FROM INFORMATION_SCHEMA.INNODB_METRIC WHERE NAME='lock_deadlocks'
innodb_lock_timeouts	Locks	db.Locks.innodb_lock_timeouts	The total number of locks that timed out.	SELECT COUNT AS innodb_lock_timeouts FROM INFORMATION_SCHEMA.INNODB_METRIC WHERE NAME='lock_timeouts'

Counter	Type	Metric	Description	Definition
innodb_row_lock_waits	Locks	db.Locks.innodb	The total number of row locks that resulted in a wait.	SELECT COUNT AS innodb_row_lock_waits FROM INFORMATION_SCHEMA.INNODB_METRICS WHERE NAME='lock_row_lock_waits'

Performance Insights counters for Amazon RDS for Microsoft SQL Server

The following database counters are available with Performance Insights for RDS for Microsoft SQL Server.

Native counters for RDS for Microsoft SQL Server

You can find definitions for these native metrics in [Use SQL Server Objects](#) in the Microsoft SQL Server documentation.

Counter	Type	Unit	Metric
Forwarded Records	Access Methods	Records per second	db.Access Methods.Forwarded Records
Page Splits	Access Methods	Splits per second	db.Access Methods.Page Splits
Buffer cache hit ratio	Buffer Manager	Ratio	db.Buffer Manager.Buffer cache hit ratio
Page life expectancy	Buffer Manager	Expectancy in seconds	db.Buffer Manager.Page life expectancy
Page lookups	Buffer Manager	Lookups per second	db.Buffer Manager.Page lookups
Page reads	Buffer Manager	Reads per second	db.Buffer Manager.Page reads
Page writes	Buffer Manager	Writes per second	db.Buffer Manager.Page writes
Active Transactions	Databases	Transactions	db.Databases.Active Transactions (_Total)
Log Bytes Flushed	Databases	Bytes flushed per second	db.Databases.Log Bytes Flushed (_Total)
Log Flush Waits	Databases	Waits per second	db.Databases.Log Flush Waits (_Total)
Log Flushes	Databases	Flushes per second	db.Databases.Log Flushes (_Total)

Counter	Type	Unit	Metric
Write Transactions	Databases	Transactions per second	db.Databases.Write Transactions (_Total)
Processes blocked	General Statistics	Processes blocked	db.General Statistics.Processes blocked
User Connections	General Statistics	Connections	db.General Statistics.User Connections
Latch Waits	Latches	Waits per second	db.Latches.Latch Waits
Number of Deadlocks	Locks	Deadlocks per second	db.Locks.Number of Deadlocks (_Total)
Memory Grants Pending	Memory Manager	Memory grants	db.Memory Manager.Memory Grants Pending
Batch Requests	SQL Statistics	Requests per second	db.SQL Statistics.Batch Requests
SQL Compilations	SQL Statistics	Compilations per second	db.SQL Statistics.SQL Compilations
SQL Re-Compilations	SQL Statistics	Re-compilations per second	db.SQL Statistics.SQL Re-Compilations

Performance Insights counters for Amazon RDS for Oracle

The following database counters are available with Performance Insights for RDS for Oracle.

Native counters for RDS for Oracle

You can find definitions for these native metrics in [Statistics Descriptions](#) in the Oracle documentation.

Note

For the CPU used by this session counter metric, the unit has been transformed from the native centiseconds to active sessions to make the value easier to use. For example, CPU send in the DB Load chart represents the demand for CPU. The counter metric CPU used by this session represents the amount of CPU used by Oracle sessions. You can compare CPU send to the CPU used by this session counter metric. When demand for CPU is higher than CPU used, sessions are waiting for CPU time.

Counter	Type	Unit	Metric
CPU used by this session	User	Active sessions	db.User.CPU used by this session
SQL*Net roundtrips to/from client	User	Roundtrips per second	db.User.SQL*Net roundtrips to/from client
Bytes received via SQL*Net from client	User	Bytes per second	db.User.bytes received via SQL*Net from client

Counter	Type	Unit	Metric
User commits	User	Commits per second	db.User.user commits
Logons cumulative	User	Logons per second	db.User.logons cumulative
User calls	User	Calls per second	db.User.user calls
Bytes sent via SQL*Net to client	User	Bytes per second	db.User.bytes sent via SQL*Net to client
User rollbacks	User	Rollbacks per second	db.User.user rollbacks
Redo size	Redo	Bytes per second	db.Redo.redo size
Parse count (total)	SQL	Parses per second	db.SQL.parse count (total)
Parse count (hard)	SQL	Parses per second	db.SQL.parse count (hard)
Table scan rows gotten	SQL	Rows per second	db.SQL.table scan rows gotten
Sorts (memory)	SQL	Sorts per second	db.SQL.sorts (memory)
Sorts (disk)	SQL	Sorts per second	db.SQL.sorts (disk)
Sorts (rows)	SQL	Sorts per second	db.SQL.sorts (rows)
Physical read bytes	Cache	Bytes per second	db.Cache.physical read bytes
DB block gets	Cache	Blocks per second	db.Cache.db block gets
DBWR checkpoints	Cache	Checkpoints per minute	db.Cache.DBWR checkpoints
Physical reads	Cache	Reads per second	db.Cache.physical reads
Consistent gets from cache	Cache	Gets per second	db.Cache.consistent gets from cache
DB block gets from cache	Cache	Gets per second	db.Cache.db block gets from cache
Consistent gets	Cache	Gets per second	db.Cache.consistent gets

Performance Insights counters for Amazon RDS for PostgreSQL

The following database counters are available with Performance Insights for Amazon RDS for PostgreSQL.

Topics

- [Native counters for Amazon RDS for PostgreSQL \(p. 453\)](#)
- [Non-native counters for Amazon RDS for PostgreSQL \(p. 454\)](#)

Native counters for Amazon RDS for PostgreSQL

You can find definitions for these native metrics in [Viewing Statistics](#) in the PostgreSQL documentation.

Counter	Type	Unit	Metric
blks_hit	Cache	Blocks per second	db.Cache.blks_hit
buffers_alloc	Cache	Blocks per second	db.Cache.buffers_alloc
buffers_checkpoint	Checkpoint	Blocks per second	db.Checkpoint.buffers_checkpoint
checkpoint_sync_time	Checkpoint	Milliseconds per checkpoint	db.Checkpoint.checkpoint_sync_time
checkpoint_write_time	Checkpoint	Milliseconds per checkpoint	db.Checkpoint.checkpoint_write_time
checkpoints_req	Checkpoint	Checkpoints per minute	db.Checkpoint.checkpoints_req
checkpoints_timed	Checkpoint	Checkpoints per minute	db.Checkpoint.checkpoints_timed
maxwritten_clean	Checkpoint	Bgwriter clean stops per minute	db.Checkpoint.maxwritten_clean
deadlocks	Concurrency	Deadlocks per minute	db.Concurrency.deadlocks
blk_read_time	I/O	Milliseconds	db.IO.blk_read_time
blks_read	I/O	Blocks per second	db.IO.blks_read
buffers_backend	I/O	Blocks per second	db.IO.buffers_backend
buffers_backend_fsync	I/O	Blocks per second	db.IO.buffers_backend_fsync
buffers_clean	I/O	Blocks per second	db.IO.buffers_clean
tup_deleted	SQL	Tuples per second	db.SQL.tup_deleted
tup_fetched	SQL	Tuples per second	db.SQL.tup_fetched
tup_inserted	SQL	Tuples per second	db.SQL.tup_inserted
tup_returned	SQL	Tuples per second	db.SQL.tup_returned
tup_updated	SQL	Tuples per second	db.SQL.tup_updated
temp_bytes	Temp	Bytes per second	db.Temp.temp_bytes
temp_files	Temp	Files per minute	db.Temp.temp_files
active_transactions	Transactions	Transactions	db.Transactions.active_transactions
blocked_transactions	Transactions	Transactions	db.Transactions.blocked_transactions
max_used_xact_ids	Transactions	Transactions	db.Transactions.max_used_xact_ids
xact_commit	Transactions	Commits per second	db.Transactions.xact_commit
xact_rollback	Transactions	Rollbacks per second	db.Transactions.xact_rollback
numbackends	User	Connections	db.User.numbackends

Counter	Type	Unit	Metric
archived_count	Write-ahead log (WAL)	Files per minute	db.WAL.archived_count
archive_failed_count	WAL	Files per minute	db.WAL.archive_failed_count

Non-native counters for Amazon RDS for PostgreSQL

Non-native counter metrics are counters defined by Amazon RDS. A non-native metric can be a metric that you get with a specific query. A non-native metric also can be a derived metric, where two or more native counters are used in calculations for ratios, hit rates, or latencies.

Counter	Type	Metric	Description	Definition
checkpoint_sync_time	Checkpoint	db.Checkpoint.checkpoint_sync_time	The total time spent in milliseconds that has been spent in the portion of checkpoint processing where files are synchronized to disk.	checkpoint_sync_time / (checkpoints_timed + checkpoints_req)
checkpoint_write_time	Checkpoint	db.Checkpoint.checkpoint_write_time	The total time spent in milliseconds that has been spent in the portion of checkpoint processing where files are written to disk.	checkpoint_write_time / (checkpoints_timed + checkpoints_req)
read_latency	I/O	db.IO.read_latency	The time spent reading data file blocks by backends in this instance.	blk_read_time / blks_read

Retrieving data with the Performance Insights API

When Performance Insights is enabled for supported engine types, the API provides visibility into instance performance. Amazon CloudWatch Logs provides the authoritative source for vended monitoring metrics for AWS services.

Performance Insights offers a domain-specific view of database load measured as average active sessions (AAS). This metric appears to API consumers as a two-dimensional time-series dataset. The time dimension of the data provides DB load data for each time point in the queried time range. Each time point decomposes overall load in relation to the requested dimensions, such as `SQL`, `Wait-event`, `User`, or `Host`, measured at that time point.

Amazon RDS Performance Insights monitors your Amazon RDS DB instance so that you can analyze and troubleshoot database performance. One way to view Performance Insights data is in the AWS Management Console. Performance Insights also provides a public API so that you can query your own data. You can use the API to offload data into a database, add Performance Insights data to existing monitoring dashboards, or to build monitoring tools. To use the Performance Insights API, enable Performance Insights on one of your Amazon RDS DB instances. For information about enabling Performance Insights, see [Enabling and disabling Performance Insights \(p. 415\)](#).

The Performance Insights API provides the following operations.

Performance Insights Operation	AWS CLI Command	Description
DescribeDimensionKeys	<code>aws pi describe-dimension-keys</code>	Retrieves the top N dimension keys for a metric for a specific time period.
GetResourceMetrics	<code>aws pi get-resource-metrics</code>	Retrieves Performance Insights metrics for a set of data sources, over a time period. You can provide specific dimension groups and dimensions, and provide aggregation and filtering criteria for each group.

For more information about the Performance Insights API, see the [Amazon RDS Performance Insights API Reference](#).

AWS CLI for Performance Insights

You can view Performance Insights data using the AWS CLI. You can view help for the AWS CLI commands for Performance Insights by entering the following on the command line.

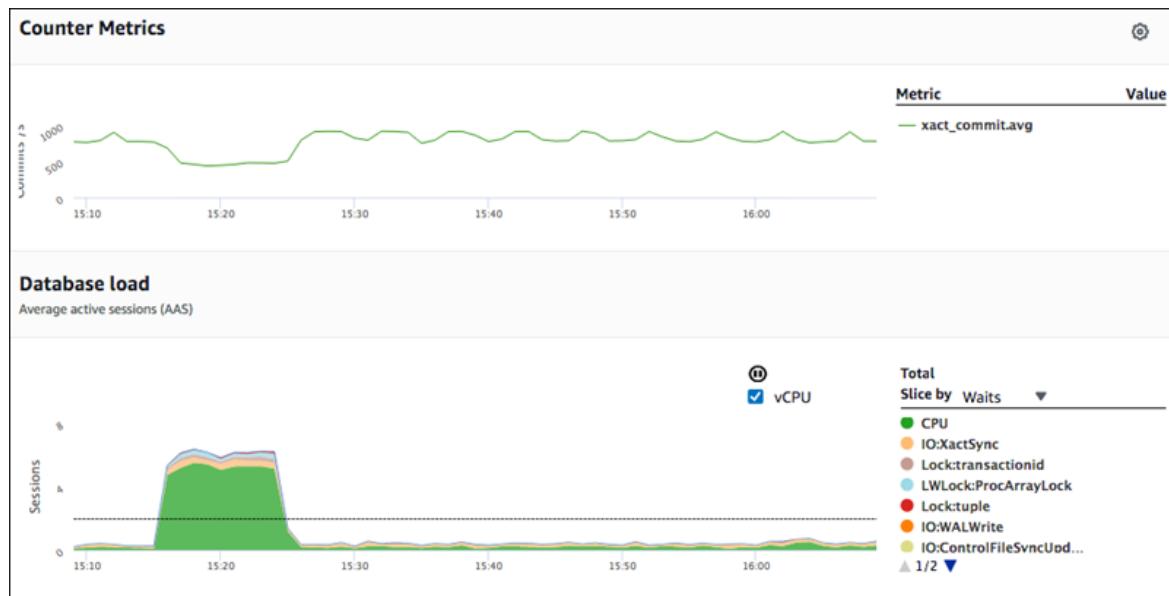

```
aws pi help
```

If you don't have the AWS CLI installed, see [Installing the AWS Command Line Interface](#) in the *AWS CLI User Guide* for information about installing it.

Retrieving time-series metrics

The GetResourceMetrics operation retrieves one or more time-series metrics from the Performance Insights data. GetResourceMetrics requires a metric and time period, and returns a response with a list of data points.

For example, the AWS Management Console uses GetResourceMetrics in two places in the Performance Insights dashboard. GetResourceMetrics is used to populate the **Counter Metrics** chart and in the **Database Load** chart, as seen in the following image.

All the metrics returned by `GetResourceMetrics` are standard time-series metrics with one exception. The exception is `db.load`, which is the core metric in Performance Insights. This metric is displayed in the **Database Load** chart. The `db.load` metric is different from the other time-series metrics because you can break it into subcomponents called dimensions. In the previous image, `db.load` is broken down and grouped by the waits states that make up the `db.load`.

Note

`GetResourceMetrics` can also return the `db.sampleload` metric, but the `db.load` metric is appropriate in most cases.

For information about the counter metrics returned by `GetResourceMetrics`, see [Customizing the Performance Insights dashboard \(p. 444\)](#).

The following calculations are supported for the metrics:

- Average – The average value for the metric over a period of time. Append `.avg` to the metric name.
- Minimum – The minimum value for the metric over a period of time. Append `.min` to the metric name.
- Maximum – The maximum value for the metric over a period of time. Append `.max` to the metric name.
- Sum – The sum of the metric values over a period of time. Append `.sum` to the metric name.
- Sample count – The number of times the metric was collected over a period of time. Append `.sample_count` to the metric name.

For example, assume that a metric is collected for 300 seconds (5 minutes), and that the metric is collected one time each minute. The values for each minute are 1, 2, 3, 4, and 5. In this case, the following calculations are returned:

- Average – 3
- Minimum – 1
- Maximum – 5
- Sum – 15
- Sample count – 5

For information about using the `get-resource-metrics` AWS CLI command, see [get-resource-metrics](#).

For the `--metric-queries` option, specify one or more queries that you want to get results for. Each query consists of a mandatory `Metric` and optional `GroupBy` and `Filter` parameters. The following is an example of a `--metric-queries` option specification.

```
{  
    "Metric": "string",  
    "GroupBy": {  
        "Group": "string",  
        "Dimensions": ["string", ...],  
        "Limit": integer  
    },  
    "Filter": {"string": "string"  
        ...}  
}
```

AWS CLI examples for Performance Insights

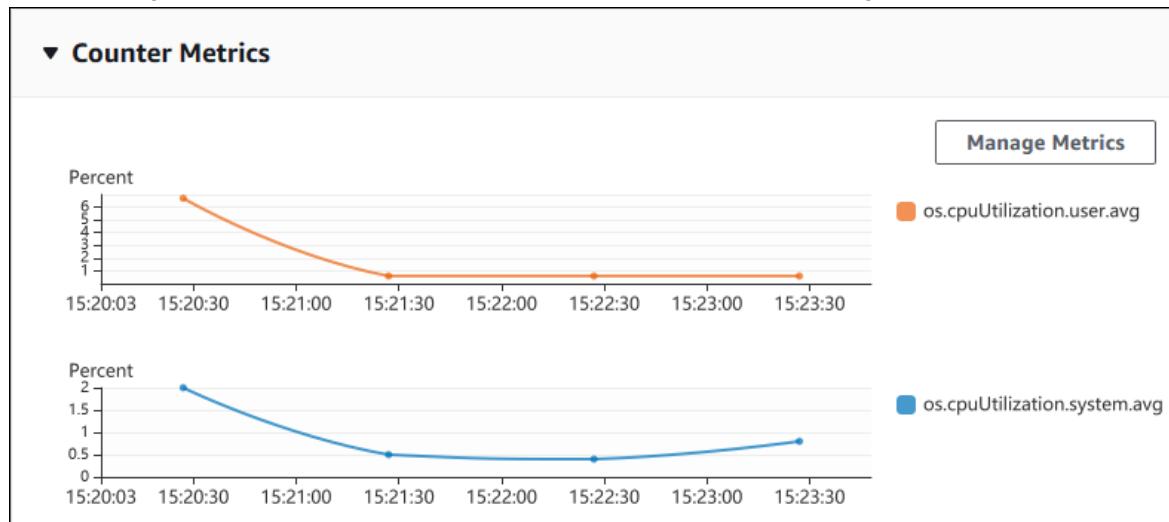

The following are several examples that use the AWS CLI for Performance Insights.

Topics

- [Retrieving counter metrics \(p. 457\)](#)
- [Retrieving the DB load average for top wait events \(p. 460\)](#)
- [Retrieving the DB load average for top SQL \(p. 462\)](#)
- [Retrieving the DB Load Average Filtered by SQL \(p. 464\)](#)

Retrieving counter metrics

The following screenshot shows two counter metrics charts in the AWS Management Console.

The following example shows how to gather the same data that the AWS Management Console uses to generate the two counter metric charts.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
--service-type RDS \
--identifier db-ID \
--start-time 2018-10-30T00:00:00Z \
--end-time 2018-10-30T01:00:00Z \
--period-in-seconds 60 \
--metric-queries '[{"Metric": "os.cpuUtilization.user.avg" },
 {"Metric": "os.cpuUtilization.idle.avg"}]'
```

For Windows:

```
aws pi get-resource-metrics ^
--service-type RDS ^
--identifier db-ID ^
--start-time 2018-10-30T00:00:00Z ^
--end-time 2018-10-30T01:00:00Z ^
--period-in-seconds 60 ^
--metric-queries '[{"Metric": "os.cpuUtilization.user.avg" },
 {"Metric": "os.cpuUtilization.idle.avg"}]'
```

You can also make a command easier to read by specifying a file for the --metrics-query option. The following example uses a file called query.json for the option. The file has the following contents.

```
[  
 {  
     "Metric": "os.cpuUtilization.user.avg"  
 },  
 {  
     "Metric": "os.cpuUtilization.idle.avg"  
 }]
```

Run the following command to use the file.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
--service-type RDS \
--identifier db-ID \
--start-time 2018-10-30T00:00:00Z \
--end-time 2018-10-30T01:00:00Z \
--period-in-seconds 60 \
--metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^
--service-type RDS ^
--identifier db-ID ^
--start-time 2018-10-30T00:00:00Z ^
--end-time 2018-10-30T01:00:00Z ^
```

```
--period-in-seconds 60 ^
--metric-queries file://query.json
```

The preceding example specifies the following values for the options:

- `--service-type` – RDS for Amazon RDS
- `--identifier` – The resource ID for the DB instance
- `--start-time` and `--end-time` – The ISO 8601 DateTime values for the period to query, with multiple supported formats

It queries for a one-hour time range:

- `--period-in-seconds` – 60 for a per-minute query
- `--metric-queries` – An array of two queries, each just for one metric.

The metric name uses dots to classify the metric in a useful category, with the final element being a function. In the example, the function is `avg` for each query. As with Amazon CloudWatch, the supported functions are `min`, `max`, `total`, and `avg`.

The response looks similar to the following.

```
{
    "Identifier": "db-XXX",
    "AlignedStartTime": 1540857600.0,
    "AlignedEndTime": 1540861200.0,
    "MetricList": [
        { //A list of key/datapoints
            "Key": {
                "Metric": "os.cpuUtilization.user.avg" //Metric1
            },
            "DataPoints": [
                //Each list of datapoints has the same timestamps and same number of items
                {
                    "Timestamp": 1540857660.0, //Minute1
                    "Value": 4.0
                },
                {
                    "Timestamp": 1540857720.0, //Minute2
                    "Value": 4.0
                },
                {
                    "Timestamp": 1540857780.0, //Minute 3
                    "Value": 10.0
                }
                //... 60 datapoints for the os.cpuUtilization.user.avg metric
            ]
        },
        {
            "Key": {
                "Metric": "os.cpuUtilization.idle.avg" //Metric2
            },
            "DataPoints": [
                {
                    "Timestamp": 1540857660.0, //Minute1
                    "Value": 12.0
                },
                {
                    "Timestamp": 1540857720.0, //Minute2
                    "Value": 10.0
                }
            ]
        }
    ]
}
```

```

        "Value": 13.5
    },
    //... 60 datapoints for the os.cpuUtilization.idle.avg metric
]
}
] //end of MetricList
} //end of response

```

The response has an `Identifier`, `AlignedStartTime`, and `AlignedEndTime`. Because the `--period-in-seconds` value was 60, the start and end times have been aligned to the minute. If the `--period-in-seconds` was 3600, the start and end times would have been aligned to the hour.

The `MetricList` in the response has a number of entries, each with a `Key` and a `DataPoints` entry. Each `DataPoint` has a `Timestamp` and a `Value`. Each `DataPoints` list has 60 data points because the queries are for per-minute data over an hour, with `Timestamp1/Minute1`, `Timestamp2/Minute2`, and so on, up to `Timestamp60/Minute60`.

Because the query is for two different counter metrics, there are two elements in the response `MetricList`.

Retrieving the DB load average for top wait events

The following example is the same query that the AWS Management Console uses to generate a stacked area line graph. This example retrieves the `db.load.avg` for the last hour with load divided according to the top seven wait events. The command is the same as the command in [Retrieving counter metrics \(p. 457\)](#). However, the `query.json` file has the following contents.

```
[
{
    "Metric": "db.load.avg",
    "GroupBy": { "Group": "db.wait_event", "Limit": 7 }
}
]
```

Run the following command.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \
--service-type RDS \
--identifier db-ID \
--start-time 2018-10-30T00:00:00Z \
--end-time 2018-10-30T01:00:00Z \
--period-in-seconds 60 \
--metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^
--service-type RDS ^
--identifier db-ID ^
--start-time 2018-10-30T00:00:00Z ^
--end-time 2018-10-30T01:00:00Z ^
--period-in-seconds 60 ^
--metric-queries file://query.json
```

The example specifies the metric of `db.load.avg` and a `GroupBy` of the top seven wait events. For details about valid values for this example, see [DimensionGroup](#) in the *Performance Insights API Reference*.

The response looks similar to the following.

```
{
    "Identifier": "db-XXX",
    "AlignedStartTime": 1540857600.0,
    "AlignedEndTime": 1540861200.0,
    "MetricList": [
        { //A list of key/datapoints
            "Key": {
                //A Metric with no dimensions. This is the total db.load.avg
                "Metric": "db.load.avg"
            },
            "DataPoints": [
                //Each list of datapoints has the same timestamps and same number of items
                {
                    "Timestamp": 1540857660.0, //Minute1
                    "Value": 0.5166666666666667
                },
                {
                    "Timestamp": 1540857720.0, //Minute2
                    "Value": 0.3833333333333336
                },
                {
                    "Timestamp": 1540857780.0, //Minute 3
                    "Value": 0.2666666666666666
                }
                //... 60 datapoints for the total db.load.avg key
            ]
        },
        {
            "Key": {
                //Another key. This is db.load.avg broken down by CPU
                "Metric": "db.load.avg",
                "Dimensions": {
                    "db.wait_event.name": "CPU",
                    "db.wait_event.type": "CPU"
                }
            },
            "DataPoints": [
                {
                    "Timestamp": 1540857660.0, //Minute1
                    "Value": 0.35
                },
                {
                    "Timestamp": 1540857720.0, //Minute2
                    "Value": 0.15
                }
                //... 60 datapoints for the CPU key
            ]
        },
        //... In total we have 8 key/datapoints entries, 1) total, 2-8) Top Wait Events
    ] //end of MetricList
} //end of response
}
```

In this response, there are eight entries in the `MetricList`. There is one entry for the total `db.load.avg`, and seven entries each for the `db.load.avg` divided according to one of the top seven wait events. Unlike in the first example, because there was a grouping dimension, there must be one key for each grouping of the metric. There can't be only one key for each metric, as in the basic counter metric use case.

Retrieving the DB load average for top SQL

The following example groups db.wait_events by the top 10 SQL statements. There are two different groups for SQL statements:

- db.sql – The full SQL statement, such as `select * from customers where customer_id = 123`
- db.sql_tokenized – The tokenized SQL statement, such as `select * from customers where customer_id = ?`

When analyzing database performance, it can be useful to consider SQL statements that only differ by their parameters as one logic item. So, you can use db.sql_tokenized when querying. However, especially when you are interested in explain plans, sometimes it's more useful to examine full SQL statements with parameters, and query grouping by db.sql. There is a parent-child relationship between tokenized and full SQL, with multiple full SQL (children) grouped under the same tokenized SQL (parent).

The command in this example is the similar to the command in [Retrieving the DB load average for top wait events \(p. 460\)](#). However, the query.json file has the following contents.

```
[  
  {  
    "Metric": "db.load.avg",  
    "GroupBy": { "Group": "db.sql_tokenized", "Limit": 10 }  
  }  
]
```

The following example uses db.sql_tokenized.

For Linux, macOS, or Unix:

```
aws pi get-resource-metrics \  
  --service-type RDS \  
  --identifier db-ID \  
  --start-time 2018-10-29T00:00:00Z \  
  --end-time 2018-10-30T00:00:00Z \  
  --period-in-seconds 3600 \  
  --metric-queries file://query.json
```

For Windows:

```
aws pi get-resource-metrics ^  
  --service-type RDS ^  
  --identifier db-ID ^  
  --start-time 2018-10-29T00:00:00Z ^  
  --end-time 2018-10-30T00:00:00Z ^  
  --period-in-seconds 3600 ^  
  --metric-queries file://query.json
```

This example queries over 24 hours, with a one hour period-in-seconds.

The example specifies the metric of db.load.avg and a GroupBy of the top seven wait events. For details about valid values for this example, see [DimensionGroup](#) in the *Performance Insights API Reference*.

The response looks similar to the following.

```
{
    "AlignedStartTime": 1540771200.0,
    "AlignedEndTime": 1540857600.0,
    "Identifier": "db-XXX",

    "MetricList": [ //11 entries in the MetricList
        {
            "Key": { //First key is total
                "Metric": "db.load.avg"
            }
            "DataPoints": [ //Each DataPoints list has 24 per-hour Timestamps and a value
                {
                    "Value": 1.6964980544747081,
                    "Timestamp": 1540774800.0
                },
                //... 24 datapoints
            ]
        },
        {
            "Key": { //Next key is the top tokenized SQL
                "Dimensions": {
                    "db.sql_tokenized.statement": "INSERT INTO authors (id,name,email)
VALUES\n( nextval('') ,?,?)",
                    "db.sql_tokenized.db_id": "pi-2372568224",
                    "db.sql_tokenized.id": "AKIAIOSFODNN7EXAMPLE"
                },
                "Metric": "db.load.avg"
            },
            "DataPoints": [ //... 24 datapoints
            ]
        },
        // In total 11 entries, 10 Keys of top tokenized SQL, 1 total key
    ] //End of MetricList
} //End of response
}
```

This response has 11 entries in the MetricList (1 total, 10 top tokenized SQL), with each entry having 24 per-hour DataPoints.

For tokenized SQL, there are three entries in each dimensions list:

- db.sql_tokenized.statement – The tokenized SQL statement.
- db.sql_tokenized.db_id – Either the native database ID used to refer to the SQL, or a synthetic ID that Performance Insights generates for you if the native database ID isn't available. This example returns the pi-2372568224 synthetic ID.
- db.sql_tokenized.id – The ID of the query inside Performance Insights.

In the AWS Management Console, this ID is called the Support ID. It's named this because the ID is data that AWS Support can examine to help you troubleshoot an issue with your database. AWS takes the security and privacy of your data extremely seriously, and almost all data is stored encrypted with your AWS KMS customer master key (CMK). Therefore, nobody inside AWS can look at this data. In the example preceding, both the tokenized.statement and the tokenized.db_id are stored encrypted. If you have an issue with your database, AWS Support can help you by referencing the Support ID.

When querying, it might be convenient to specify a Group in GroupBy. However, for finer-grained control over the data that's returned, specify the list of dimensions. For example, if all that is needed is the db.sql_tokenized.statement, then a Dimensions attribute can be added to the query.json file.

```
[
{
```

```

        "Metric": "db.load.avg",
        "GroupBy": {
            "Group": "db.sql_tokenized",
            "Dimensions": ["db.sql_tokenized.statement"],
            "Limit": 10
        }
    }
]

```

Retrieving the DB Load Average Filtered by SQL

The preceding image shows that a particular query is selected, and the top average active sessions stacked area line graph is scoped to that query. Although the query is still for the top seven overall wait events, the value of the response is filtered. The filter causes it to take into account only sessions that are a match for the particular filter.

The corresponding API query in this example is similar to the command in [Retrieving the DB load average for top SQL \(p. 462\)](#). However, the query.json file has the following contents.

```

[
{
    "Metric": "db.load.avg",
    "GroupBy": { "Group": "db.wait_event", "Limit": 5 },
    "Filter": { "db.sql_tokenized.id": "AKIAIOSFODNN7EXAMPLE" }
}
]

```

For Linux, macOS, or Unix:

```

aws pi get-resource-metrics \
--service-type RDS \
--identifier db-ID \
--start-time 2018-10-30T00:00:00Z \
--end-time 2018-10-30T01:00:00Z \
--period-in-seconds 60 \
--metric-queries file://query.json

```

For Windows:

```
aws pi get-resource-metrics ^
--service-type RDS ^
--identifier db-ID ^
--start-time 2018-10-30T00:00:00Z ^
--end-time 2018-10-30T01:00:00Z ^
--period-in-seconds 60 ^
--metric-queries file://query.json
```

The response looks similar to the following.

```
{
  "Identifier": "db-XXX",
  "AlignedStartTime": 1556215200.0,
  "MetricList": [
    {
      "Key": {
        "Metric": "db.load.avg"
      },
      "DataPoints": [
        {
          "Timestamp": 1556218800.0,
          "Value": 1.4878117913832196
        },
        {
          "Timestamp": 1556222400.0,
          "Value": 1.192823803967328
        }
      ]
    },
    {
      "Key": {
        "Metric": "db.load.avg",
        "Dimensions": {
          "db.wait_event.type": "io",
          "db.wait_event.name": "wait/io/aurora_redo_log_flush"
        }
      },
      "DataPoints": [
        {

        "Metric": "db.load.avg",
        "Dimensions": {
            "db.wait_event.type": "synch",
            "db.wait_event.name": "wait/synch/mutex/innodb/
aurora_lock_thread_slot_futex"
        }
    },
    "DataPoints": [
        {
            "Timestamp": 1556218800.0,
            "Value": 0.11479591836734694
        },
        {
            "Timestamp": 1556222400.0,
            "Value": 0.013127187864644107
        }
    ]
},
{
    "Key": {
        "Metric": "db.load.avg",
        "Dimensions": {
            "db.wait_event.type": "CPU",
            "db.wait_event.name": "CPU"
        }
    },
    "DataPoints": [
        {
            "Timestamp": 1556218800.0,
            "Value": 0.05215419501133787
        },
        {
            "Timestamp": 1556222400.0,
            "Value": 0.05805134189031505
        }
    ]
},
{
    "Key": {
        "Metric": "db.load.avg",
        "Dimensions": {
            "db.wait_event.type": "synch",
            "db.wait_event.name": "wait/synch/mutex/innodb/lock_wait_mutex"
        }
    },
    "DataPoints": [
        {
            "Timestamp": 1556218800.0,
            "Value": 0.017573696145124718
        },
        {
            "Timestamp": 1556222400.0,
            "Value": 0.002333722287047841
        }
    ]
},
],
"AlignedEndTime": 1556222400.0
} //end of response

```

In this response, all values are filtered according to the contribution of tokenized SQL AKIAIOSFODNN7EXAMPLE specified in the query.json file. The keys also might follow a different order than a query without a filter, because it's the top five wait events that affected the filtered SQL.

Performance Insights metrics published to Amazon CloudWatch

Performance Insights automatically publishes metrics to Amazon CloudWatch. The same data can be queried from Performance Insights, but having the metrics in CloudWatch makes it easy to add CloudWatch alarms. It also makes it easy to add the metrics to existing CloudWatch Dashboards.

Metric	Description
DBLoad	The number of active sessions for the DB engine. Typically, you want the data for the average number of active sessions. In Performance Insights, this data is queried as db.load.avg.
DBLoadCPU	The number of active sessions where the wait event type is CPU. In Performance Insights, this data is queried as db.load.avg, filtered by the wait event type CPU.
DBLoadNonCPU	The number of active sessions where the wait event type is not CPU.

Note

These metrics are published to CloudWatch only if there is load on the DB instance.

You can examine these metrics using the CloudWatch console, the AWS CLI, or the CloudWatch API.

For example, you can get the statistics for the DBLoad metric by running the [get-metric-statistics](#) command.

```
aws cloudwatch get-metric-statistics \
--region us-west-2 \
--namespace AWS/RDS \
--metric-name DBLoad \
--period 60 \
--statistics Average \
--start-time 1532035185 \
--end-time 1532036185 \
--dimensions Name=DBInstanceIdentifier,Value=db-loadtest-0
```

This example generates output similar to the following.

```
{
  "Datapoints": [
    {
      "Timestamp": "2018-07-19T21:30:00Z",
      "Unit": "None",
      "Average": 2.1
    },
    ...
  ]
}
```

```
{  
  "Timestamp": "2018-07-19T21:34:00Z",  
  "Unit": "None",

],  
"Label": "DBLoad"  
}
```

For more information about CloudWatch, see [What is Amazon CloudWatch?](#) in the *Amazon CloudWatch User Guide*.

Logging Performance Insights calls by using AWS CloudTrail

Performance Insights runs with AWS CloudTrail, a service that provides a record of actions taken by a user, role, or an AWS service in Performance Insights. CloudTrail captures all API calls for Performance Insights as events. This capture includes calls from the Amazon RDS console and from code calls to the Performance Insights API operations.

If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for Performance Insights. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the data collected by CloudTrail, you can determine certain information. This information includes the request that was made to Performance Insights, the IP address the request was made from, who made the request, and when it was made. It also includes additional details.

To learn more about CloudTrail, see the [AWS CloudTrail User Guide](#).

Working with Performance Insights information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in Performance Insights, that activity is recorded in a CloudTrail event along with other AWS service events in the CloudTrail console in **Event history**. You can view, search, and download recent events in your AWS

account. For more information, see [Viewing Events with CloudTrail Event History](#) in *AWS CloudTrail User Guide*.

For an ongoing record of events in your AWS account, including events for Performance Insights, create a trail. A *trail* enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all AWS Regions. The trail logs events from all AWS Regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see the following topics in *AWS CloudTrail User Guide*:

- [Overview for Creating a Trail](#)
- [CloudTrail Supported Services and Integrations](#)
- [Configuring Amazon SNS Notifications for CloudTrail](#)
- [Receiving CloudTrail Log Files from Multiple Regions](#) and [Receiving CloudTrail Log Files from Multiple Accounts](#)

All Performance Insights operations are logged by CloudTrail and are documented in the [Performance Insights API Reference](#). For example, calls to the `DescribeDimensionKeys` and `GetResourceMetrics` operations generate entries in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information, see the [CloudTrail userIdentity Element](#).

Performance Insights log file entries

A *trail* is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An *event* represents a single request from any source. Each event includes information about the requested operation, the date and time of the operation, request parameters, and so on. CloudTrail log files aren't an ordered stack trace of the public API calls, so they don't appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `GetResourceMetrics` operation.

```
{  
    "eventVersion": "1.05",  
    "userIdentity": {  
        "type": "IAMUser",  
        "principalId": "AKIAIOSFODNN7EXAMPLE",  
        "arn": "arn:aws:iam::123456789012:user/johndoe",  
        "accountId": "123456789012",  
        "accessKeyId": "AKIAI44QH8DHBEEXAMPLE",  
        "userName": "johndoe"  
    },  
    "eventTime": "2019-12-18T19:28:46Z",  
    "eventSource": "pi.amazonaws.com",  
    "eventName": "GetResourceMetrics",  
    "awsRegion": "us-east-1",  
    "sourceIPAddress": "72.21.198.67",  
    "userAgent": "aws-cli/1.16.240 Python/3.7.4 Darwin/18.7.0 botocore/1.12.230",  
    "requestParameters": {
```

```
"identifier": "db-YTDU5J5V66X7CXSCVDFD2V3SZM",
"metricQueries": [
    {

"eventType": "AwsApiCall",
"recipientAccountId": "123456789012"
}
```

Using Enhanced Monitoring

Amazon RDS provides metrics in real time for the operating system (OS) that your DB instance runs on. You can view the metrics for your DB instance using the console. Also, you can consume the Enhanced Monitoring JSON output from Amazon CloudWatch Logs in a monitoring system of your choice.

By default, Enhanced Monitoring metrics are stored for 30 days in the CloudWatch Logs, which are different from typical CloudWatch metrics. To modify the amount of time the metrics are stored in the CloudWatch Logs, change the retention for the `RDSOSMetrics` log group in the CloudWatch console. For more information, see [Change log data retention in CloudWatch logs](#) in the *Amazon CloudWatch Logs User Guide*.

Because Enhanced Monitoring metrics are stored in the CloudWatch logs instead of in Cloudwatch metrics, the cost of Enhanced Monitoring depends on several factors:

- You are only charged for Enhanced Monitoring that exceeds the free tier provided by Amazon CloudWatch Logs.

For more information about pricing, see [Amazon CloudWatch pricing](#).
- A smaller monitoring interval results in more frequent reporting of OS metrics and increases your monitoring cost.
- Usage costs for Enhanced Monitoring are applied for each DB instance that Enhanced Monitoring is enabled for. Monitoring a large number of DB instances is more expensive than monitoring only a few.
- DB instances that support a more compute-intensive workload have more OS process activity to report and higher costs for Enhanced Monitoring.

Enhanced Monitoring availability

Enhanced Monitoring is available for the following database engines:

- MariaDB
- Microsoft SQL Server
- MySQL version 5.5 or later
- Oracle
- PostgreSQL

Enhanced Monitoring is available for all DB instance classes except for the db.m1.small instance class.

Differences between CloudWatch and Enhanced Monitoring metrics

CloudWatch gathers metrics about CPU utilization from the hypervisor for a DB instance, and Enhanced Monitoring gathers its metrics from an agent on the instance. As a result, you might find differences between the measurements, because the hypervisor layer performs a small amount of work. The differences can be greater if your DB instances use smaller instance classes, because then there are likely more virtual machines (VMs) that are managed by the hypervisor layer on a single physical instance. Enhanced Monitoring metrics are useful when you want to see how different processes or threads on a DB instance use the CPU.

Setting up and enabling Enhanced Monitoring

To use Enhanced Monitoring, you must create an IAM role, and then enable Enhanced Monitoring.

Creating an IAM role for Enhanced Monitoring

Enhanced Monitoring requires permission to act on your behalf to send OS metric information to CloudWatch Logs. You grant Enhanced Monitoring permissions using an AWS Identity and Access Management (IAM) role.

Creating the IAM role when you enable Enhanced Monitoring

When you enable Enhanced Monitoring in the RDS console, Amazon RDS can create the required IAM role for you. The role is named `rds-monitoring-role`. RDS uses this role for the specified DB instance or read replica.

To create the IAM role when enabling Enhanced Monitoring

1. Follow the steps in [Enabling and disabling Enhanced Monitoring \(p. 472\)](#).
2. Set **Monitoring Role** to **Default** in the step where you choose a role.

Creating the IAM role before you enable Enhanced Monitoring

You can create the required role before you enable Enhanced Monitoring. When you enable Enhanced Monitoring, specify your new role's name. You must create this required role if you enable Enhanced Monitoring using the AWS CLI or the RDS API.

The user that enables Enhanced Monitoring must be granted the `PassRole` permission. For more information, see Example 2 in [Granting a user permissions to pass a role to an AWS service](#) in the *IAM User Guide*.

To create an IAM role for Amazon RDS enhanced monitoring

1. Open the [IAM console](#) at <https://console.aws.amazon.com>.
2. In the navigation pane, choose **Roles**.
3. Choose **Create role**.
4. Choose the **AWS service** tab, and then choose **RDS** from the list of services.
5. Choose **RDS - Enhanced Monitoring**, and then choose **Next: Permissions**.
6. Ensure that the **Attached permissions policy** page shows `AmazonRDSEnhancedMonitoringRole`, and then choose **Next: Tags**.
7. On the **Add tags** page, choose **Next: Review**.
8. For **Role Name**, enter a name for your role. For example, enter `emaccess`.

The trusted entity for your role is the AWS service `monitoring.rds.amazonaws.com`.

9. Choose **Create role**.

Enabling and disabling Enhanced Monitoring

You can enable and disable Enhanced Monitoring using the AWS Management Console, AWS CLI, or RDS API.

Console

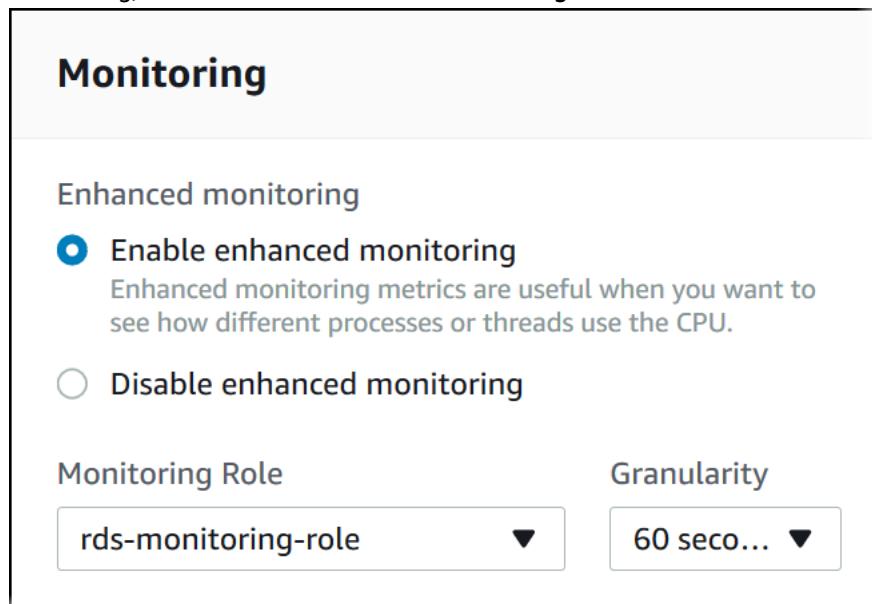

You can enable Enhanced Monitoring when you create a DB instance or read replica, or when you modify a DB instance. If you modify a DB instance to enable Enhanced Monitoring, you don't need to reboot your DB instance for the change to take effect.

You can enable Enhanced Monitoring in the RDS console when you do one of the following actions:

- **Create a DB instance** – You can enable Enhanced Monitoring in the **Monitoring** section under **Additional configuration**.
- **Create a read replica** – You can enable Enhanced Monitoring in the **Monitoring** section.
- **Modify a DB instance** – You can enable Enhanced Monitoring in the **Monitoring** section.

To enable Enhanced Monitoring by using the RDS console

1. Scroll to the **Monitoring** section.
2. Choose **Enable enhanced monitoring** for your DB instance or read replica. To disable Enhanced Monitoring, choose **Disable enhanced monitoring**.

3. Set the **Monitoring Role** property to the IAM role that you created to permit Amazon RDS to communicate with Amazon CloudWatch Logs for you, or choose **Default** to have RDS create a role for you named `rds-monitoring-role`.
4. Set the **Granularity** property to the interval, in seconds, between points when metrics are collected for your DB instance or read replica. The **Granularity** property can be set to one of the following values: 1, 5, 10, 15, 30, or 60.

Note

The fastest that the RDS console refreshes is every 5 seconds. If you set the granularity to 1 second in the RDS console, you still see updated metrics only every 5 seconds. You can retrieve 1-second metric updates by using CloudWatch Logs.

AWS CLI

To enable Enhanced Monitoring using the AWS CLI, in the following commands, set the `--monitoring-interval` option to a value other than 0 and set the `--monitoring-role-arn` option to the role you created in [Creating an IAM role for Enhanced Monitoring \(p. 472\)](#).

- `create-db-instance`
- `create-db-instance-read-replica`
- `modify-db-instance`

The `--monitoring-interval` option specifies the interval, in seconds, between points when Enhanced Monitoring metrics are collected. Valid values for the option are 0, 1, 5, 10, 15, 30, and 60.

To disable Enhanced Monitoring using the AWS CLI, set the `--monitoring-interval` option to 0 in the these commands.

Example

The following example enables Enhanced Monitoring for a DB instance:

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --monitoring-interval 30 \
    --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --monitoring-interval 30 ^
    --monitoring-role-arn arn:aws:iam::123456789012:role/emaccess
```

RDS API

To enable Enhanced Monitoring using the RDS API, set the `MonitoringInterval` parameter to a value other than 0 and set the `MonitoringRoleArn` parameter to the role you created in [Creating an IAM role for Enhanced Monitoring \(p. 472\)](#). Set these parameters in the following actions:

- [CreateDBInstance](#)
- [CreateDBInstanceReadReplica](#)
- [ModifyDBInstance](#)

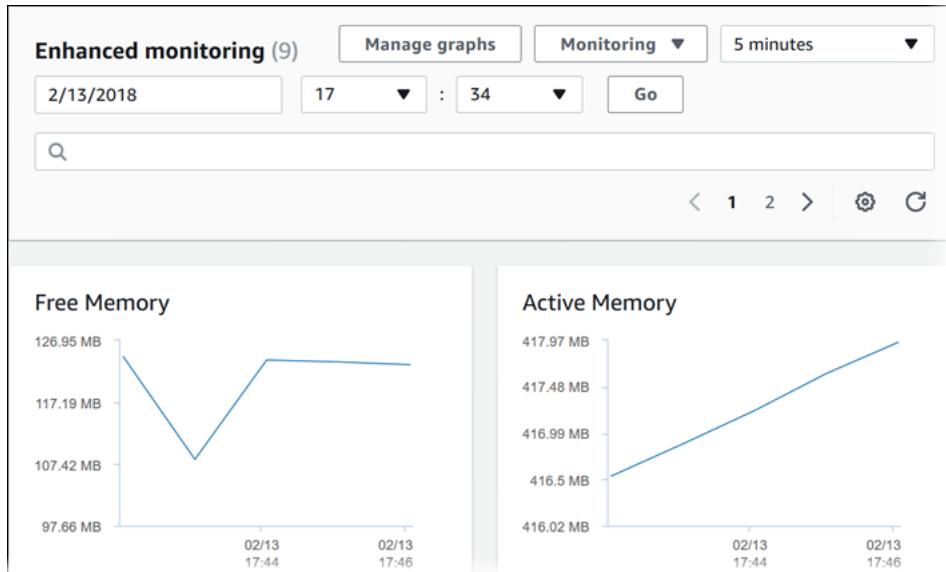

The `MonitoringInterval` parameter specifies the interval, in seconds, between points when Enhanced Monitoring metrics are collected. Valid values are 0, 1, 5, 10, 15, 30, and 60.

To disable Enhanced Monitoring using the RDS API, set `MonitoringInterval` to 0.

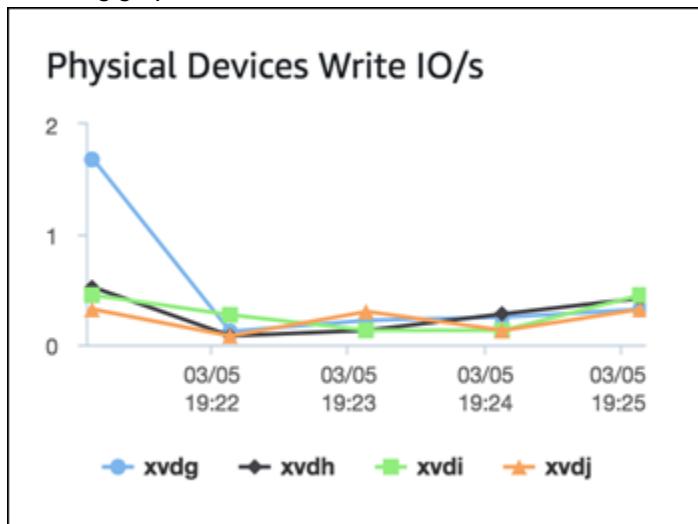

Viewing Enhanced Monitoring

You can view OS metrics reported by Enhanced Monitoring in the RDS console by choosing **Enhanced monitoring for Monitoring**.

The Enhanced Monitoring page is shown following.

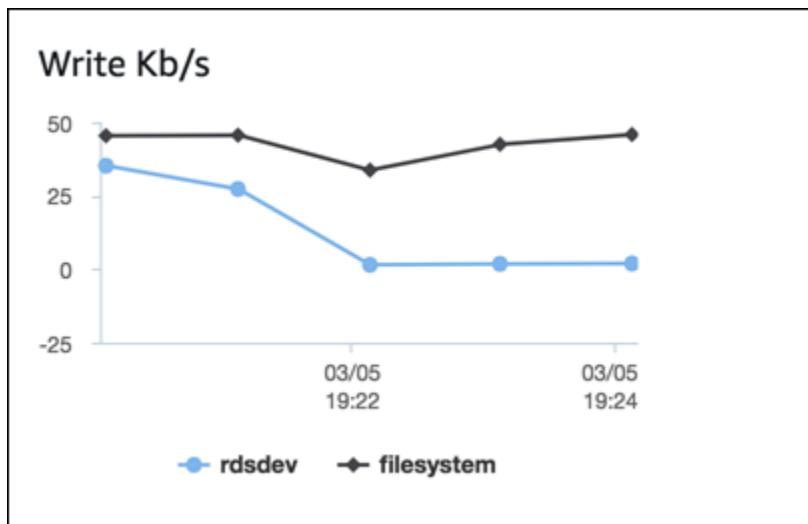

Some DB instances use more than one disk for the DB instance's data storage volume. On those DB instances, the **Physical Devices** graphs show metrics for each one of the disks. For example, the following graph shows metrics for four disks.

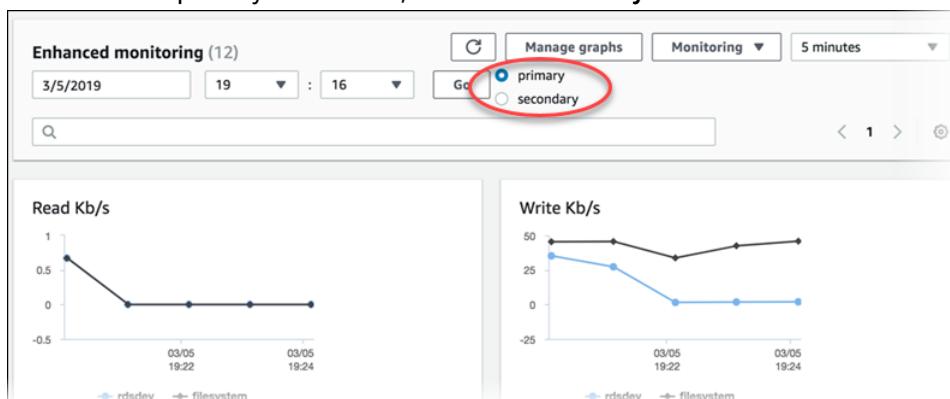

Note

Currently, **Physical Devices** graphs are not available for Microsoft SQL Server DB instances.

When you are viewing aggregated **Disk I/O** and **File system** graphs, the **rdsdev** device relates to the **/rdsdbdata** file system, where all database files and logs are stored. The **filesystem** device relates to the **/** file system (also known as root), where files related to the operating system are stored.

If the DB instance is a Multi-AZ deployment, you can view the OS metrics for the primary DB instance and its Multi-AZ standby replica. In the **Enhanced monitoring** view, choose **primary** to view the OS metrics for the primary DB instance, or choose **secondary** to view the OS metrics for the standby replica.

For more information about Multi-AZ deployments, see [High availability \(Multi-AZ\) for Amazon RDS \(p. 53\)](#).

Note

Currently, viewing OS metrics for a Multi-AZ standby replica is not supported for MariaDB or Microsoft SQL Server DB instances.

If you want to see details for the processes running on your DB instance, choose **OS process list** for **Monitoring**.

The **Process List** view is shown following.

Process List					
<input type="text"/> Filter process list					
NAME	VIRT	RES	CPU%	MEM%	VMLIMIT
postgres [3181] ^t	283.55 MB	17.11 MB	0.02	1.72	
postgres:					
rdsadmin	384.7 MB	9.51 MB	0.02	0.95	
rdsadmin					
localhost(40156)					
idle [2953] ^t					

The Enhanced Monitoring metrics shown in the **Process list** view are organized as follows:

- **RDS child processes** – Shows a summary of the RDS processes that support the DB instance, for example `mysqld` for MySQL DB instances. Process threads appear nested beneath the parent process. Process threads show CPU utilization only as other metrics are the same for all threads for the process. The console displays a maximum of 100 processes and threads. The results are a combination of the top CPU consuming and memory consuming processes and threads. If there are more than 50 processes and more than 50 threads, the console displays the top 50 consumers in each category. This display helps you identify which processes are having the greatest impact on performance.
- **RDS processes** – Shows a summary of the resources used by the RDS management agent, diagnostics monitoring processes, and other AWS processes that are required to support RDS DB instances.
- **OS processes** – Shows a summary of the kernel and system processes, which generally have minimal impact on performance.

Note

The **Process list** view might sometimes contain internal, undocumented processes.

The items listed for each process are:

- **VIRT** – Displays the virtual size of the process.
- **RES** – Displays the actual physical memory being used by the process.
- **CPU%** – Displays the percentage of the total CPU bandwidth being used by the process.
- **MEM%** – Displays the percentage of the total memory being used by the process.

The monitoring data that is shown in the RDS console is retrieved from Amazon CloudWatch Logs. You can also retrieve the metrics for a DB instance as a log stream from CloudWatch Logs. For more information, see [Viewing Enhanced Monitoring by using CloudWatch Logs \(p. 478\)](#).

Enhanced Monitoring metrics are not returned during the following:

- A failover of the DB instance.
- Changing the instance class of the DB instance (scale compute).

Enhanced Monitoring metrics are returned during a reboot of a DB instance because only the database engine is rebooted. Metrics for the operating system are still reported.

Viewing Enhanced Monitoring by using CloudWatch Logs

After you have enabled Enhanced Monitoring for your DB instance, you can view the metrics for your DB instance using CloudWatch Logs, with each log stream representing a single DB instance being monitored. The log stream identifier is the resource identifier (`DbiResourceId`) for the DB instance.

To view Enhanced Monitoring log data

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. If necessary, choose the region that your DB instance is in. For more information, see [Regions and endpoints](#) in the *Amazon Web Services General Reference*.
3. Choose **Logs** in the navigation pane.
4. Choose **RDSOSMetrics** from the list of log groups.

In a Multi-AZ deployment, log files with `-secondary` appended to the name are for the Multi-AZ standby replica.

The screenshot shows the CloudWatch Log Groups interface. The top navigation bar includes 'CloudWatch' and 'Log Groups'. Below it, there are three buttons: 'Search Log Group', 'Create Log Stream', and 'Delete Log Stream'. A 'Filter' input field is set to 'Log Stream Name Prefix'. The main area displays a table of log streams. The first row has a checkbox and the text 'Log Streams'. The second row contains a checkbox, the log stream name 'db-SORJBHOPBSMWGRI5EJW3KMYOTU-secondary', and the 'Last Event Time' '2019-03-05 12:12 UTC-8'. The third row contains a checkbox, the log stream name 'db-SORJBHOPBSMWGRI5EJW3KMYOTU', and the 'Last Event Time' '2019-03-05 12:07 UTC-8'. A red box highlights the log stream name in the second row.

5. Choose the log stream that you want to view from the list of log streams.

Available OS metrics

The following tables list the OS metrics available using Amazon CloudWatch Logs.

Metrics for MariaDB, MySQL, Oracle, and PostgreSQL DB instances

Group	Metric	Console name	Description
General	engine	Not applicable	The database engine for the DB instance.
	instanceID	Not applicable	The DB instance identifier.
	instanceResouceID	Not applicable	An immutable identifier for the DB instance that is unique to an AWS Region, also used as the log stream identifier.
	numVCPU	Not applicable	The number of virtual CPUs for the DB instance.

Group	Metric	Console name	Description
	timestamp	Not applicable	The time at which the metrics were taken.
	uptime	Not applicable	The amount of time that the DB instance has been active.
	version	Not applicable	The version of the OS metrics' stream JSON format.
cpuUtilization	guest	CPU Guest	The percentage of CPU in use by guest programs.
	idle	CPU Idle	The percentage of CPU that is idle.
	irq	CPU IRQ	The percentage of CPU in use by software interrupts.
	nice	CPU Nice	The percentage of CPU in use by programs running at lowest priority.
	steal	CPU Steal	The percentage of CPU in use by other virtual machines.
	system	CPU System	The percentage of CPU in use by the kernel.
	total	CPU Total	The total percentage of the CPU in use. This value includes the nice value.
	user	CPU User	The percentage of CPU in use by user programs.
	wait	CPU Wait	The percentage of CPU unused while waiting for I/O access.
diskIO	avgQueueLen	Avg Queue Size	The number of requests waiting in the I/O device's queue.
	avgReqSz	Ave Request Size	The average request size, in kilobytes.
	await	Disk I/O Await	The number of milliseconds required to respond to requests, including queue time and service time.
	device	Not applicable	The identifier of the disk device in use.
	readIOsPS	Read IO/s	The number of read operations per second.
	readKb	Read Total	The total number of kilobytes read.
	readKbPS	Read Kb/s	The number of kilobytes read per second.
	readLatency	Read Latency	The elapsed time between the submission of a read I/O request and its completion, in milliseconds. This metric is only available for Amazon Aurora.
	readThroughput	Read Throughput	The amount of network throughput used by requests to the DB cluster, in bytes per second. This metric is only available for Amazon Aurora.
	rrqmPS	Rrqms	The number of merged read requests queued per second.

Group	Metric	Console name	Description
physicalDeviceIOPs	tps	TPS	The number of I/O transactions per second.
	util	Disk I/O Util	The percentage of CPU time during which requests were issued.
	writeIOsPS	Write IO/s	The number of write operations per second.
	writeKb	Write Total	The total number of kilobytes written.
	writeKbPS	Write Kb/s	The number of kilobytes written per second.
	writeLatency	Write Latency	The average elapsed time between the submission of a write I/O request and its completion, in milliseconds. This metric is only available for Amazon Aurora.
	writeThroughput	Write Throughput	The amount of network throughput used by responses from the DB cluster, in bytes per second. This metric is only available for Amazon Aurora.
	wrqmPS	Wrqms	The number of merged write requests queued per second.
	physicalDeviceReqQueueLen	Physical Devices Avg Queue Size	The number of requests waiting in the I/O device's queue.
	avgReqSz	Physical Devices Ave Request Size	The average request size, in kilobytes.
	await	Physical Devices Disk I/O Await	The number of milliseconds required to respond to requests, including queue time and service time.
	device	Not applicable	The identifier of the disk device in use.
	readIOsPS	Physical Devices Read IO/s	The number of read operations per second.
	readKb	Physical Devices Read Total	The total number of kilobytes read.
	readKbPS	Physical Devices Read Kb/s	The number of kilobytes read per second.
	rrqmPS	Physical Devices Rrqms	The number of merged read requests queued per second.
	tps	Physical Devices TPS	The number of I/O transactions per second.

Group	Metric	Console name	Description
	util	Physical Devices Disk I/O Util	The percentage of CPU time during which requests were issued.
	writeIOPSPS	Physical Devices Write IO/s	The number of write operations per second.
	writeKb	Physical Devices Write Total	The total number of kilobytes written.
	writeKbPS	Physical Devices Write Kb/s	The number of kilobytes written per second.
	wrqmPS	Physical Devices Wrqms	The number of merged write requests queued per second.
fileSys	maxFiles	Max Inodes	The maximum number of files that can be created for the file system.
	mountPoint	Not applicable	The path to the file system.
	name	Not applicable	The name of the file system.
	total	Total Filesystem	The total number of disk space available for the file system, in kilobytes.
	used	Used Filesystem	The amount of disk space used by files in the file system, in kilobytes.
	usedFilePercent	Used %	The percentage of available files in use.
	usedFiles	Used Inodes	The number of files in the file system.
	usedPercent	Used Inodes %	The percentage of the file-system disk space in use.
loadAverage	fifteen	Load Avg 15 min	The number of processes requesting CPU time over the last 15 minutes.
	five	Load Avg 5 min	The number of processes requesting CPU time over the last 5 minutes.
	one	Load Avg 1 min	The number of processes requesting CPU time over the last minute.
memory	active	Active Memory	The amount of assigned memory, in kilobytes.
	buffers	Buffered Memory	The amount of memory used for buffering I/O requests prior to writing to the storage device, in kilobytes.

Group	Metric	Console name	Description
memory	cached	Cached Memory	The amount of memory used for caching file system-based I/O.
	dirty	Dirty Memory	The amount of memory pages in RAM that have been modified but not written to their related data block in storage, in kilobytes.
	free	Free Memory	The amount of unassigned memory, in kilobytes.
	hugePagesFree	Huge Pages Free	The number of free huge pages. Huge pages are a feature of the Linux kernel.
	hugePagesRsvd	Huge Pages Rsvd	The number of committed huge pages.
	hugePagesSize	Huge Pages Size	The size for each huge pages unit, in kilobytes.
	hugePagesSurp	Huge Pages Surp	The number of available surplus huge pages over the total.
	hugePagesTotal	Huge Pages Total	The total number of huge pages.
	inactive	Inactive Memory	The amount of least-frequently used memory pages, in kilobytes.
	mapped	Mapped Memory	The total amount of file-system contents that is memory mapped inside a process address space, in kilobytes.
	pageTables	Page Tables	The amount of memory used by page tables, in kilobytes.
	slab	Slab Memory	The amount of reusable kernel data structures, in kilobytes.
	total	Total Memory	The total amount of memory, in kilobytes.
	writeback	Writeback Memory	The amount of dirty pages in RAM that are still being written to the backing storage, in kilobytes.
network	interface	Not applicable	The identifier for the network interface being used for the DB instance.
	rx	RX	The number of bytes received per second.
	tx	TX	The number of bytes uploaded per second.
processList	cpuUsedPc	CPU %	The percentage of CPU used by the process.
	id	Not applicable	The identifier of the process.
	memoryUsedPc	MEM%	The percentage of memory used by the process.
	name	Not applicable	The name of the process.

Group	Metric	Console name	Description
	parentID	Not applicable	The process identifier for the parent process of the process.
	rss	RES	The amount of RAM allocated to the process, in kilobytes.
	tgid	Not applicable	The thread group identifier, which is a number representing the process ID to which a thread belongs. This identifier is used to group threads from the same process.
	vss	VIRT	The amount of virtual memory allocated to the process, in kilobytes.
swap	swap	Swap	The amount of swap memory available, in kilobytes.
	swap_in	Swaps in	The amount of memory, in kilobytes, swapped in from disk.
	swap_out	Swaps out	The amount of memory, in kilobytes, swapped out to disk.
	free	Free Swap	The amount of swap memory free, in kilobytes.
	committed	Committed Swap	The amount of swap memory, in kilobytes, used as cache memory.
tasks	blocked	Tasks Blocked	The number of tasks that are blocked.
	running	Tasks Running	The number of tasks that are running.
	sleeping	Tasks Sleeping	The number of tasks that are sleeping.
	stopped	Tasks Stopped	The number of tasks that are stopped.
	total	Tasks Total	The total number of tasks.
	zombie	Tasks Zombie	The number of child tasks that are inactive with an active parent task.

Metrics for Microsoft SQL Server DB instances

Group	Metric	Console name	Description
General	engine	Not applicable	The database engine for the DB instance.
	instanceID	Not applicable	The DB instance identifier.
	instanceResourceIdentifier	Not applicable	An immutable identifier for the DB instance that is unique to an AWS Region, also used as the log stream identifier.
	numVCpus	Not applicable	The number of virtual CPUs for the DB instance.

Group	Metric	Console name	Description
	timestamp	Not applicable	The time at which the metrics were taken.
	uptime	Not applicable	The amount of time that the DB instance has been active.
	version	Not applicable	The version of the OS metrics' stream JSON format.
cpuUtilization	idle	CPU Idle	The percentage of CPU that is idle.
	kern	CPU Kernel	The percentage of CPU in use by the kernel.
	user	CPU User	The percentage of CPU in use by user programs.
disks	name	Not applicable	The identifier for the disk.
	totalKb	Total Disk Space	The total space of the disk, in kilobytes.
	usedKb	Used Disk Space	The amount of space used on the disk, in kilobytes.
	usedPc	Used Disk Space %	The percentage of space used on the disk.
	availKb	Available Disk Space	The space available on the disk, in kilobytes.
	availPc	Available Disk Space %	The percentage of space available on the disk.
	rdCountPS	Reads/s	The number of read operations per second
	rdBytesPS	Read Kb/s	The number of bytes read per second.
	wrCountPS	Write IO/s	The number of write operations per second.
	wrBytesPS	Write Kb/s	The amount of bytes written per second.
memory	commitTotKb	Commit Total	The amount of pagefile-backed virtual address space in use, that is, the current commit charge. This value is composed of main memory (RAM) and disk (pagefiles).
	commitLimitKb	Maximum Commit	The maximum possible value for the commitTotKb metric. This value is the sum of the current pagefile size plus the physical memory available for pageable contents, excluding RAM that is assigned to nonpageable areas.
	commitPeakKb	Commit Peak	The largest value of the commitTotKb metric since the operating system was last started.
	kernTotKb	Total Kernel Memory	The sum of the memory in the paged and nonpaged kernel pools, in kilobytes.
	kernPagedKb	Paged Kernel Memory	The amount of memory in the paged kernel pool, in kilobytes.

Group	Metric	Console name	Description
	kernNonpagedKb	Nonpaged Kernel Memory	The amount of memory in the nonpaged kernel pool, in kilobytes.
	pageSize	Page Size	The size of a page, in bytes.
	physTotKb	Total Memory	The amount of physical memory, in kilobytes.
	physAvailKb	Available Memory	The amount of available physical memory, in kilobytes.
	sqlServerTotKb	SQL Server Total Memory	The amount of memory committed to SQL Server, in kilobytes.
	sysCacheKb	System Cache	The amount of system cache memory, in kilobytes.
network	interface	Not applicable	The identifier for the network interface being used for the DB instance.
	rdBytesPS	Network Read Kb/s	The number of bytes received per second.
	wrBytesPS	Network Write Kb/s	The number of bytes sent per second.
processList	cpuUsedPc	Used %	The percentage of CPU used by the process.
	memUsedPc	MEM%	The percentage of total memory used by the process.
	name	Not applicable	The name of the process.
	pid	Not applicable	The identifier of the process. This value is not present for processes that are owned by Amazon RDS.
	ppid	Not applicable	The process identifier for the parent of this process. This value is only present for child processes.
	tid	Not applicable	The thread identifier. This value is only present for threads. The owning process can be identified by using the pid value.
	workingSetKb	Not applicable	The amount of memory in the private working set plus the amount of memory that is in use by the process and can be shared with other processes, in kilobytes.
	workingSetPrivKb	Not applicable	The amount of memory that is in use by a process, but can't be shared with other processes, in kilobytes.
	workingSetShareableKb	Not applicable	The amount of memory that is in use by a process and can be shared with other processes, in kilobytes.

Group	Metric	Console name	Description
	virtKb	Not applicable	The amount of virtual address space the process is using, in kilobytes. Use of virtual address space doesn't necessarily imply corresponding use of either disk or main memory pages.
system	handles	Handles	The number of handles that the system is using.
	processes	Processes	The number of processes running on the system.
	threads	Threads	The number of threads running on the system.

Using Amazon RDS event notification

Amazon RDS uses the Amazon Simple Notification Service (Amazon SNS) to provide notification when an Amazon RDS event occurs. These notifications can be in any notification form supported by Amazon SNS for an AWS Region, such as an email, a text message, or a call to an HTTP endpoint.

Amazon RDS groups these events into categories that you can subscribe to so that you can be notified when an event in that category occurs. You can subscribe to an event category for a DB instance, DB snapshot, DB parameter group, or DB security group. For example, if you subscribe to the Backup category for a given DB instance, you are notified whenever a backup-related event occurs that affects the DB instance. If you subscribe to a configuration change category for a DB security group, you are notified when the DB security group is changed. You also receive notification when an event notification subscription changes.

Event notifications are sent to the addresses that you provide when you create the subscription. You might want to create several different subscriptions, such as one subscription receiving all event notifications and another subscription that includes only critical events for your production DB instances. You can easily turn off notification without deleting a subscription by choosing **No** for **Enabled** in the Amazon RDS console or by setting the `Enabled` parameter to `false` using the AWS CLI or Amazon RDS API.

Important

Amazon RDS doesn't guarantee the order of events sent in an event stream. The event order is subject to change.

Note

For more information on using text messages with SNS, see [Mobile text messaging \(SMS\)](#) in the [Amazon Simple Notification Service Developer Guide](#).

Amazon RDS uses the ARN of an Amazon SNS topic to identify each subscription. The Amazon RDS console creates the ARN for you when you create the subscription. If you use the CLI or API, you create the ARN by using the Amazon SNS console or the Amazon SNS API when you create a subscription.

Billing for Amazon RDS event notification is through the Amazon Simple Notification Service (Amazon SNS). Amazon SNS fees apply when using event notification. For more information on Amazon SNS billing, see [Amazon Simple Notification Service pricing](#).

The process for subscribing to Amazon RDS event notification is as follows:

1. Create an Amazon RDS event notification subscription by using the Amazon RDS console, AWS CLI, or API.
2. Amazon RDS sends an approval email or SMS message to the addresses you submitted with your subscription. To confirm your subscription, choose the link in the notification you were sent.
3. When you have confirmed the subscription, the status of your subscription is updated in the Amazon RDS console's **My Event Subscriptions** section.
4. You then begin to receive event notifications.

Note

When Amazon SNS sends a notification to a subscribed HTTP or HTTPS endpoint, the POST message sent to the endpoint has a message body that contains a JSON document. For more information, see [Amazon SNS message and JSON formats](#) in the *Amazon Simple Notification Service Developer Guide*.

You can use AWS Lambda to process event notifications from a DB instance. For more information, see [Using AWS Lambda with Amazon RDS](#) in the *AWS Lambda Developer Guide*.

The following section lists all categories and events that you can be notified of. It also provides information about subscribing to and working with Amazon RDS event subscriptions.

Amazon RDS event categories and event messages

Amazon RDS generates a significant number of events in categories that you can subscribe to using the Amazon RDS Console, AWS CLI, or the API. Each category applies to a source type, which can be one of the following:

- DB instance
- DB security group
- DB parameter group

The following table shows the event category and a list of events when a DB instance is the source type.

Category	Amazon RDS event ID	Description
availability	RDS-EVENT-0006	The DB instance restarted.
availability	RDS-EVENT-0004	DB instance shutdown.
availability	RDS-EVENT-0022	An error has occurred while restarting MySQL or MariaDB.
backup	RDS-EVENT-0001	Backing up DB instance.
backup	RDS-EVENT-0002	Finished DB Instance backup.
configuration change	RDS-EVENT-0009	The DB instance has been added to a security group.
configuration change	RDS-EVENT-0024	The DB instance is being converted to a Multi-AZ DB instance.
configuration change	RDS-EVENT-0030	The DB instance is being converted to a Single-AZ DB instance.
configuration change	RDS-EVENT-0012	Applying modification to database instance class.
configuration change	RDS-EVENT-0018	The current storage settings for this DB instance are being changed.
configuration change	RDS-EVENT-0011	A parameter group for this DB instance has changed.
configuration change	RDS-EVENT-0092	A parameter group for this DB instance has finished updating.

Category	Amazon RDS event ID	Description
configuration change	RDS-EVENT-0028	Automatic backups for this DB instance have been disabled.
configuration change	RDS-EVENT-0032	Automatic backups for this DB instance have been enabled.
configuration change	RDS-EVENT-0033	There are [count] users that match the master user name. Users not tied to a specific host have been reset.
configuration change	RDS-EVENT-0025	The DB instance has been converted to a Multi-AZ DB instance.
configuration change	RDS-EVENT-0029	The DB instance has been converted to a Single-AZ DB instance.
configuration change	RDS-EVENT-0014	The DB instance class for this DB instance has changed.
configuration change	RDS-EVENT-0017	The storage settings for this DB instance have changed.
configuration change	RDS-EVENT-0010	The DB instance has been removed from a security group.
configuration change	RDS-EVENT-0016	The master password for the DB instance has been reset.
configuration change	RDS-EVENT-0067	An attempt to reset the master password for the DB instance has failed.
configuration change	RDS-EVENT-0078	The Enhanced Monitoring configuration has been changed.
creation	RDS-EVENT-0005	DB instance created.
deletion	RDS-EVENT-0003	The DB instance has been deleted.
failover	RDS-EVENT-0034	Amazon RDS is not attempting a requested failover because a failover recently occurred on the DB instance.
failover	RDS-EVENT-0013	A Multi-AZ failover that resulted in the promotion of a standby instance has started.
failover	RDS-EVENT-0015	A Multi-AZ failover that resulted in the promotion of a standby instance is complete. It may take several minutes for the DNS to transfer to the new primary DB instance.
failover	RDS-EVENT-0065	The instance has recovered from a partial failover.
failover	RDS-EVENT-0049	A Multi-AZ failover has completed.
failover	RDS-EVENT-0050	A Multi-AZ activation has started after a successful instance recovery.
failover	RDS-EVENT-0051	A Multi-AZ activation is complete. Your database should be accessible now.

Category	Amazon RDS event ID	Description
failure	RDS-EVENT-0031	The DB instance has failed due to an incompatible configuration or an underlying storage issue. Begin a point-in-time-restore for the DB instance.
failure	RDS-EVENT-0036	The DB instance is in an incompatible network. Some of the specified subnet IDs are invalid or do not exist.
failure	RDS-EVENT-0035	The DB instance has invalid parameters. For example, if the DB instance could not start because a memory-related parameter is set too high for this instance class, the customer action would be to modify the memory parameter and reboot the DB instance.
failure	RDS-EVENT-0058	Error while creating Statspack user account PERFSTAT. Please drop the account before adding the Statspack option.
failure	RDS-EVENT-0079	Enhanced Monitoring cannot be enabled without the enhanced monitoring IAM role. For information on creating the enhanced monitoring IAM role, see To create an IAM role for Amazon RDS enhanced monitoring (p. 472) .
failure	RDS-EVENT-0080	Enhanced Monitoring was disabled due to an error making the configuration change. It is likely that the enhanced monitoring IAM role is configured incorrectly. For information on creating the enhanced monitoring IAM role, see To create an IAM role for Amazon RDS enhanced monitoring (p. 472) .
failure	RDS-EVENT-0081	The IAM role that you use to access your Amazon S3 bucket for SQL Server native backup and restore is configured incorrectly. For more information, see Setting up for native backup and restore (p. 672) .
failure	RDS-EVENT-0188	Amazon RDS was unable to upgrade a MySQL DB instance from version 5.7 to version 8.0 because of incompatibilities related to the data dictionary. The DB instance was rolled back to MySQL version 5.7. For more information, see Rollback after failure to upgrade from MySQL 5.7 to 8.0 (p. 857) .
low storage	RDS-EVENT-0089	The DB instance has consumed more than 90% of its allocated storage. You can monitor the storage space for a DB instance using the Free Storage Space metric. For more information, see Viewing DB instance metrics (p. 548) .
low storage	RDS-EVENT-0007	The allocated storage for the DB instance has been consumed. To resolve this issue, allocate additional storage for the DB instance. For more information, see the RDS FAQ . You can monitor the storage space for a DB instance using the Free Storage Space metric. For more information, see Viewing DB instance metrics (p. 548) .

Category	Amazon RDS event ID	Description
maintenance	RDS-EVENT-0026	Offline maintenance of the DB instance is taking place. The DB instance is currently unavailable.
maintenance	RDS-EVENT-0027	Offline maintenance of the DB instance is complete. The DB instance is now available.
maintenance	RDS-EVENT-0047	Patching of the DB instance has completed.
maintenance	RDS-EVENT-0155	The DB instance has a DB engine minor version upgrade available.
notification	RDS-EVENT-0044	Operator-issued notification. For more information, see the event message.
notification	RDS-EVENT-0048	Patching of the DB instance has been delayed.
notification	RDS-EVENT-0054	The MySQL storage engine you are using is not InnoDB, which is the recommended MySQL storage engine for Amazon RDS. For information about MySQL storage engines, see Supported storage engines for MySQL on Amazon RDS .
notification	RDS-EVENT-0055	<p>The number of tables you have for your DB instance exceeds the recommended best practices for Amazon RDS. Please reduce the number of tables on your DB instance.</p> <p>For information about recommended best practices, see Amazon RDS basic operational guidelines (p. 128).</p>
notification	RDS-EVENT-0056	<p>The number of databases you have for your DB instance exceeds the recommended best practices for Amazon RDS. Please reduce the number of databases on your DB instance.</p> <p>For information about recommended best practices, see Amazon RDS basic operational guidelines (p. 128).</p>
notification	RDS-EVENT-0064	The TDE key has been rotated. For information about recommended best practices, see Amazon RDS basic operational guidelines (p. 128) .
notification	RDS-EVENT-0084	You attempted to convert a DB instance to Multi-AZ, but it contains in-memory file groups that are not supported for Multi-AZ. For more information, see Multi-AZ deployments for Microsoft SQL Server (p. 698) .
notification	RDS-EVENT-0087	The DB instance has been stopped.
notification	RDS-EVENT-0088	The DB instance has been started.
notification	RDS-EVENT-0154	The DB instance is being started due to it exceeding the maximum allowed time being stopped.

Category	Amazon RDS event ID	Description
notification	RDS-EVENT-0157	<p>RDS can't modify the DB instance class because the target instance class can't support the number of databases that exist on the source DB instance. The error message appears as: "The instance has N databases, but after conversion it would only support N".</p> <p>For more information, see Limits for Microsoft SQL Server DB instances (p. 632).</p>
notification	RDS-EVENT-0158	DB instance is in a state that can't be upgraded.
read replica	RDS-EVENT-0045	<p>An error has occurred in the read replication process. For more information, see the event message.</p> <p>In addition, see the troubleshooting section for read replicas for your DB engine.</p> <ul style="list-style-type: none"> • Troubleshooting a MariaDB read replica problem (p. 612) • Troubleshooting a SQL Server read replica problem (p. 697) • Troubleshooting a MySQL read replica problem (p. 908) • Troubleshooting Oracle replicas (p. 1124) • Troubleshooting a PostgreSQL read replica problem (p. 1546)
read replica	RDS-EVENT-0046	The read replica has resumed replication. This message appears when you first create a read replica, or as a monitoring message confirming that replication is functioning properly. If this message follows an RDS-EVENT-0045 notification, then replication has resumed following an error or after replication was stopped.
read replica	RDS-EVENT-0057	Replication on the read replica was terminated.
read replica	RDS-EVENT-0062	Replication on the read replica was manually stopped.
read replica	RDS-EVENT-0063	Replication on the read replica was reset.
recovery	RDS-EVENT-0020	Recovery of the DB instance has started. Recovery time will vary with the amount of data to be recovered.
recovery	RDS-EVENT-0021	Recovery of the DB instance is complete.
recovery	RDS-EVENT-0023	A manual backup has been requested but Amazon RDS is currently in the process of creating a DB snapshot. Submit the request again after Amazon RDS has completed the DB snapshot.
recovery	RDS-EVENT-0052	Recovery of the Multi-AZ instance has started. Recovery time will vary with the amount of data to be recovered.

Category	Amazon RDS event ID	Description
recovery	RDS-EVENT-0053	Recovery of the Multi-AZ instance is complete.
recovery	RDS-EVENT-0066	The SQL Server DB instance is re-establishing its mirror. Performance will be degraded until the mirror is reestablished. A database was found with non-FULL recovery model. The recovery model was changed back to FULL and mirroring recovery was started. (<dbname>: <recovery model found>[,...])"
restoration	RDS-EVENT-0008	The DB instance has been restored from a DB snapshot.
restoration	RDS-EVENT-0019	The DB instance has been restored from a point-in-time backup.

The following table shows the event category and a list of events when a DB parameter group is the source type.

Category	RDS event ID	Description
configuration change	RDS-EVENT-0037	The parameter group was modified.

The following table shows the event category and a list of events when a DB security group is the source type.

Category	RDS event ID	Description
configuration change	RDS-EVENT-0038	The security group has been modified.
failure	RDS-EVENT-0039	The security group owned by [user] does not exist; authorization for the security group has been revoked.

The following table shows the event category and a list of events when a DB snapshot is the source type.

Category	RDS event ID	Description
creation	RDS-EVENT-0040	A manual DB snapshot is being created.
creation	RDS-EVENT-0042	A manual DB snapshot has been created.
creation	RDS-EVENT-0090	An automated DB snapshot is being created.
creation	RDS-EVENT-0091	An automated DB snapshot has been created.
deletion	RDS-EVENT-0041	A DB snapshot has been deleted.
notification	RDS-EVENT-0059	Started copy of snapshot [DB snapshot name] from region [region name].

Category	RDS event ID	Description
notification	RDS-EVENT-0060	Finished copy of snapshot [DB snapshot name] from region [region name] in [time] minutes.
notification	RDS-EVENT-0061	Canceled snapshot copy request of [DB snapshot name] from region %[region name].
notification	RDS-EVENT-0159	DB snapshot export task failed.
notification	RDS-EVENT-0160	DB snapshot export task canceled.
notification	RDS-EVENT-0161	DB snapshot export task completed.
restoration	RDS-EVENT-0043	A DB instance is being restored from a DB snapshot.

Subscribing to Amazon RDS event notification

You can create an Amazon RDS event notification subscription so you can be notified when an event occurs for a given DB instance, DB snapshot, DB security group, or DB parameter group. The simplest way to create a subscription is with the RDS console. If you choose to create event notification subscriptions using the CLI or API, you must create an Amazon Simple Notification Service topic and subscribe to that topic with the Amazon SNS console or Amazon SNS API. You will also need to retain the Amazon Resource Name (ARN) of the topic because it is used when submitting CLI commands or API operations. For information on creating an SNS topic and subscribing to it, see [Getting started with Amazon SNS](#) in the *Amazon Simple Notification Service Developer Guide*.

You can specify the type of source you want to be notified of and the Amazon RDS source that triggers the event. These are defined by the **SourceType** (type of source) and the **SourceIdentifier** (the Amazon RDS source generating the event). If you specify both the **SourceType** and **SourceIdentifier**, such as `SourceType = db-instance` and `SourceIdentifier = myDBInstance1`, you receive all the DB instance events for the specified source. If you specify a **SourceType** but don't specify a **SourceIdentifier**, you receive notice of the events for that source type for all your Amazon RDS sources. If you don't specify either the **SourceType** or the **SourceIdentifier**, you are notified of events generated from all Amazon RDS sources belonging to your customer account.

Note

Event notifications might take up to five minutes to be delivered.

Amazon RDS event notification is only available for unencrypted SNS topics. If you specify an encrypted SNS topic, event notifications aren't sent for the topic.

Console

To subscribe to RDS event notification

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In navigation pane, choose **Event subscriptions**.
3. In the **Event subscriptions** pane, choose **Create event subscription**.
4. In the **Create event subscription** dialog box, do the following:
 - a. For **Name**, enter a name for the event notification subscription.
 - b. For **Send notifications to**, choose an existing Amazon SNS ARN for an Amazon SNS topic, or choose **create topic** to enter the name of a topic and a list of recipients.
 - c. For **Source type**, choose a source type.

- d. Choose **Yes** to enable the subscription. If you want to create the subscription but to not have notifications sent yet, choose **No**.
- e. Depending on the source type you selected, choose the event categories and sources that you want to receive event notifications for.
- f. Choose **Create**.

The Amazon RDS console indicates that the subscription is being created.

Event subscriptions (2)				
		Edit	Delete	Create event subscription
<input type="text"/> Filter event subscriptions		< 1 >	<input type="radio"/>	<input type="radio"/>
Name	Status	Source Type	Enabled	
Configchangerdpgres	active	Instances	Yes	
Test	creating	Instances	Yes	

AWS CLI

To subscribe to RDS event notification, use the AWS CLI [create-event-subscription](#) command. Include the following required parameters:

- `--subscription-name`
- `--sns-topic-arn`

Example

For Linux, macOS, or Unix:

```
aws rds create-event-subscription \
--subscription-name myeventsubscription \
--sns-topic-arn arn:aws:sns:us-east-1:802#####:myawsuser-RDS \
--enabled
```

For Windows:

```
aws rds create-event-subscription ^
--subscription-name myeventsubscription ^
--sns-topic-arn arn:aws:sns:us-east-1:802#####:myawsuser-RDS ^
--enabled
```

API

To subscribe to Amazon RDS event notification, call the Amazon RDS API function [CreateEventSubscription](#). Include the following required parameters:

- `SubscriptionName`
- `SnsTopicArn`

Listing Amazon RDS event notification subscriptions

You can list your current Amazon RDS event notification subscriptions.

Console

To list your current Amazon RDS event notification subscriptions

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Event subscriptions**. The **Event subscriptions** pane shows all your event notification subscriptions.

Event subscriptions (2)		
	Name	Status
<input type="checkbox"/>	Configchangerdpgres	active
<input type="checkbox"/>	Postgresnotification	active

AWS CLI

To list your current Amazon RDS event notification subscriptions, use the AWS CLI [describe-event-subscriptions](#) command.

Example

The following example describes all event subscriptions.

```
aws rds describe-event-subscriptions
```

The following example describes the `myfirsteventsubscription`.

```
aws rds describe-event-subscriptions --subscription-name myfirsteventsubscription
```

API

To list your current Amazon RDS event notification subscriptions, call the Amazon RDS API [DescribeEventSubscriptions](#) action.

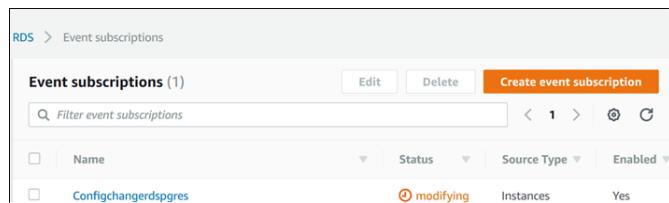

Modifying an Amazon RDS event notification subscription

After you have created a subscription, you can change the subscription name, source identifier, categories, or topic ARN.

Console

To modify an Amazon RDS event notification subscription

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Event subscriptions**.
3. In the **Event subscriptions** pane, choose the subscription that you want to modify and choose **Edit**.
4. Make your changes to the subscription in either the **Target** or **Source** section.
5. Choose **Edit**. The Amazon RDS console indicates that the subscription is being modified.

AWS CLI

To modify an Amazon RDS event notification subscription, use the AWS CLI [modify-event-subscription](#) command. Include the following required parameter:

- `--subscription-name`

Example

The following code enables `myeventsSubscription`.

For Linux, macOS, or Unix:

```
aws rds modify-event-subscription \
--subscription-name myeventsSubscription \
--enabled
```

For Windows:

```
aws rds modify-event-subscription ^
--subscription-name myeventsSubscription ^
--enabled
```

API

To modify an Amazon RDS event, call the Amazon RDS API operation [ModifyEventSubscription](#). Include the following required parameter:

- SubscriptionName

Adding a source identifier to an Amazon RDS event notification subscription

You can add a source identifier (the Amazon RDS source generating the event) to an existing subscription.

Console

You can easily add or remove source identifiers using the Amazon RDS console by selecting or deselecting them when modifying a subscription. For more information, see [Modifying an Amazon RDS event notification subscription \(p. 497\)](#).

AWS CLI

To add a source identifier to an Amazon RDS event notification subscription, use the AWS CLI [add-source-identifier-to-subscription](#) command. Include the following required parameters:

- `--subscription-name`
- `--source-identifier`

Example

The following example adds the source identifier `mysqldb` to the `myrdseventsSubscription` subscription.

For Linux, macOS, or Unix:

```
aws rds add-source-identifier-to-subscription \
  --subscription-name myrdseventsSubscription \
  --source-identifier mysqldb
```

For Windows:

```
aws rds add-source-identifier-to-subscription ^
  --subscription-name myrdseventsSubscription ^
  --source-identifier mysqldb
```

API

To add a source identifier to an Amazon RDS event notification subscription, call the Amazon RDS API [AddSourceIdentifierToSubscription](#). Include the following required parameters:

- `SubscriptionName`
- `SourceIdentifier`

Removing a source identifier from an Amazon RDS event notification subscription

You can remove a source identifier (the Amazon RDS source generating the event) from a subscription if you no longer want to be notified of events for that source.

Console

You can easily add or remove source identifiers using the Amazon RDS console by selecting or deselecting them when modifying a subscription. For more information, see [Modifying an Amazon RDS event notification subscription \(p. 497\)](#).

AWS CLI

To remove a source identifier from an Amazon RDS event notification subscription, use the AWS CLI `remove-source-identifier-from-subscription` command. Include the following required parameters:

- `--subscription-name`
- `--source-identifier`

Example

The following example removes the source identifier `mysqldb` from the `myrdseventsSubscription` subscription.

For Linux, macOS, or Unix:

```
aws rds remove-source-identifier-from-subscription \
--subscription-name myrdseventsSubscription \
--source-identifier mysqldb
```

For Windows:

```
aws rds remove-source-identifier-from-subscription ^
--subscription-name myrdseventsSubscription ^
--source-identifier mysqldb
```

API

To remove a source identifier from an Amazon RDS event notification subscription, use the Amazon RDS API `RemoveSourceIdentifierFromSubscription` command. Include the following required parameters:

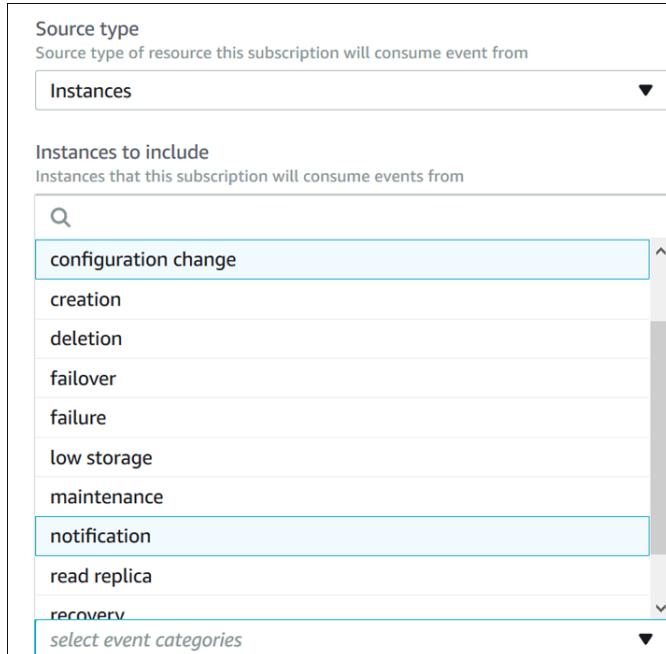

- `SubscriptionName`
- `SourceIdentifier`

List the Amazon RDS event notification categories

All events for a resource type are grouped into categories. To view the list of categories available, use the following procedures.

Console

When you create or modify an event notification subscription, the event categories are displayed in the Amazon RDS console. For more information, see [Modifying an Amazon RDS event notification subscription \(p. 497\)](#).

AWS CLI

To list the Amazon RDS event notification categories, use the AWS CLI `describe-event-categories` command. This command has no required parameters.

Example

```
aws rds describe-event-categories
```

API

To list the Amazon RDS event notification categories, use the Amazon RDS API `DescribeEventCategories` command. This command has no required parameters.

Deleting an Amazon RDS event notification subscription

You can delete a subscription when you no longer need it. All subscribers to the topic will no longer receive event notifications specified by the subscription.

Console

To delete an Amazon RDS event notification subscription

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **DB Event Subscriptions**.
3. In the **My DB Event Subscriptions** pane, choose the subscription that you want to delete.
4. Choose **Delete**.
5. The Amazon RDS console indicates that the subscription is being deleted.

The screenshot shows the 'Event subscriptions' section of the AWS RDS console. It displays two entries:

Name	Status
Configchangerdpgres	active
Postgresnotification	active

AWS CLI

To delete an Amazon RDS event notification subscription, use the AWS CLI `delete-event-subscription` command. Include the following required parameter:

- `--subscription-name`

Example

The following example deletes the subscription `myrdssubscription`.

```
aws rds delete-event-subscription --subscription-name myrdssubscription
```

API

To delete an Amazon RDS event notification subscription, use the RDS API `DeleteEventSubscription` command. Include the following required parameter:

- `SubscriptionName`

Viewing Amazon RDS events

Amazon RDS keeps a record of events that relate to your DB instances, DB snapshots, DB security groups, and DB parameter groups. This information includes the date and time of the event, the source name and source type of the event, and a message associated with the event.

You can retrieve events for your RDS resources through the AWS Management Console, which shows events from the past 24 hours. You can also retrieve events for your RDS resources by using the [describe-events](#) AWS CLI command, or the [DescribeEvents](#) RDS API operation. If you use the AWS CLI or the RDS API to view events, you can retrieve events for up to the past 14 days.

Note

If you need to store events for longer periods of time, you can send Amazon RDS events to CloudWatch Events. For more information, see [Getting CloudWatch Events and Amazon EventBridge events for Amazon RDS \(p. 551\)](#)

Console

To view all Amazon RDS instance events for the past 24 hours

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Events**. The available events appear in a list.
3. Use the **Filter** list to filter the events by type, and use the text box to the right of the **Filter** list to further filter your results. For example, the following screenshot shows a list of events filtered by the characters **stopped**.

The screenshot shows the AWS Management Console interface for viewing RDS events. The top navigation bar has 'RDS' and 'Events'. Below it, a search bar contains the text 'stopped'. A table displays one event row:

Source	Type	Time	Message
orclb	Instances	March 19, 2021, 7:34:09 PM UTC	DB instance stopped

AWS CLI

You can view all Amazon RDS instance events for the past 7 days by calling the [describe-events](#) AWS CLI command and setting the `--duration` parameter to 10080.

```
aws rds describe-events --duration 10080
```

API

You can view all Amazon RDS instance events for the past 14 days by calling the [DescribeEvents](#) RDS API operation and setting the `Duration` parameter to 20160.

Accessing Amazon RDS database log files

You can view, download, and watch database logs using the AWS Management Console, the AWS Command Line Interface (AWS CLI), or the Amazon RDS API. Viewing, downloading, or watching transaction logs isn't supported.

For engine-specific information, see the following:

- [MariaDB database log files \(p. 508\)](#)
- [Microsoft SQL Server database log files \(p. 516\)](#)
- [Accessing MySQL database log files \(p. 519\)](#)
- [Oracle database log files \(p. 527\)](#)
- [PostgreSQL database log files \(p. 534\)](#)

Viewing and listing database log files

You can view database log files for your DB engine by using the AWS Management Console. You can list what log files are available for download or monitoring by using the AWS CLI or Amazon RDS API.

Note

If you can't view the list of log files for an existing Oracle DB instance, reboot the instance to view the list.

Console

To view a database log file

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. In the **Logs** section, choose the log that you want to view, and then choose **View**.

AWS CLI

To list the available database log files for a DB instance, use the AWS CLI `describe-db-log-files` command.

The following example returns a list of log files for a DB instance named `my-db-instance`.

Example

```
aws rds describe-db-log-files --db-instance-identifier my-db-instance
```

RDS API

To list the available database log files for a DB instance, use the Amazon RDS API `DescribeDBLogFiles` action.

Downloading a database log file

You can use the AWS Management Console, AWS CLI or API to download a database log file.

Console

To download a database log file

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. Scroll down to the **Logs** section.
6. In the **Logs** section, choose the button next to the log that you want to download, and then choose **Download**.
7. Open the context (right-click) menu for the link provided, and then choose **Save Link As**. Enter the location where you want the log file to be saved, and then choose **Save**.

AWS CLI

To download a database log file, use the AWS CLI command `download-db-log-file-portion`. By default, this command downloads only the latest portion of a log file. However, you can download an entire file by specifying the parameter `--starting-token 0`.

The following example shows how to download the entire contents of a log file called `log/ERROR.4` and store it in a local file called `errorlog.txt`.

Example

For Linux, macOS, or Unix:

```
aws rds download-db-log-file-portion \
    --db-instance-identifier myexampledb \
    --starting-token 0 --output text \
    --log-file-name log/ERROR.4 > errorlog.txt
```

For Windows:

```
aws rds download-db-log-file-portion ^
    --db-instance-identifier myexampledb ^
    --starting-token 0 --output text ^
    --log-file-name log/ERROR.4 > errorlog.txt
```

RDS API

To download a database log file, use the Amazon RDS API `DownloadDBLogFilePortion` action.

Watching a database log file

You can monitor the contents of a log file by using the AWS Management Console.

Console

To watch a database log file

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that has the log file that you want to view.
4. Choose the **Logs & events** tab.
5. In the **Logs** section, choose a log file, and then choose **Watch**.

Publishing database logs to Amazon CloudWatch Logs

In addition to viewing and downloading DB instance logs, you can publish logs to Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, store the data in highly durable storage, and manage the data with the CloudWatch Logs Agent. AWS retains log data published to CloudWatch Logs for an indefinite time period unless you specify a retention period. For more information, see [Change log data retention in CloudWatch Logs](#).

For engine-specific information, see the following:

- the section called “Publishing MariaDB logs to Amazon CloudWatch Logs” (p. 509)
- the section called “Publishing MySQL logs to Amazon CloudWatch Logs” (p. 521)
- the section called “Publishing Oracle logs to Amazon CloudWatch Logs” (p. 529)
- the section called “Publishing PostgreSQL logs to Amazon CloudWatch Logs” (p. 537)
- the section called “Publishing SQL Server logs to Amazon CloudWatch Logs” (p. 516)

Reading log file contents using REST

Amazon RDS provides a REST endpoint that allows access to DB instance log files. This is useful if you need to write an application to stream Amazon RDS log file contents.

The syntax is:

```
GET /v13/downloadCompleteLogFile/DBInstanceIdentifier/LogFileName HTTP/1.1
Content-type: application/json
host: rds.region.amazonaws.com
```

The following parameters are required:

- *DBInstanceIdentifier*—the name of the DB instance that contains the log file you want to download.
- *LogFileName*—the name of the log file to be downloaded.

The response contains the contents of the requested log file, as a stream.

The following example downloads the log file named *log/ERROR.6* for the DB instance named *sample-sql* in the *us-west-2* region.

```
GET /v13/downloadCompleteLogFile/sample-sql/log/ERROR.6 HTTP/1.1
host: rds.us-west-2.amazonaws.com
X-Amz-Security-Token: AQoDYXdzEIH//////////wEa0AIXLhngC5zp9CyB1R6abwKrXHVR5efnAVN3XvR7IwqKYalFSn6UyJuEFTft9nObglx4QJ+GXV9cpACkETq=
X-Amz-Date: 20140903T233749Z
X-Amz-Algorithm: AWS4-HMAC-SHA256
X-Amz-Credential: AKIADQKE4SARGYLE/20140903/us-west-2/rds/aws4_request
X-Amz-SignedHeaders: host
X-Amz-Content-SHA256: e3b0c44298fc1c229afbf4c8996fb92427ae41e4649b934de495991b7852b855
X-Amz-Expires: 86400
X-Amz-Signature: 353a4f14b3f250142d9afc34f9f9948154d46ce7d4ec091d0cdabbcf8b40c558
```

If you specify a nonexistent DB instance, the response consists of the following error:

- **DBInstanceNotFound**—*DB Instance Identifier* does not refer to an existing DB instance. (HTTP status code: 404)

MariaDB database log files

You can monitor the MariaDB error log, slow query log, and the general log. The MariaDB error log is generated by default; you can generate the slow query and general logs by setting parameters in your DB parameter group. Amazon RDS rotates all of the MariaDB log files; the intervals for each type are given following.

You can monitor the MariaDB logs directly through the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs. You can also access MariaDB logs by directing the logs to a database table in the main database and querying that table. You can use the `mysqlbinlog` utility to download a binary log.

For more information about viewing, downloading, and watching file-based database logs, see [Accessing Amazon RDS database log files \(p. 504\)](#).

Accessing MariaDB error logs

The MariaDB error log is written to the `<host-name>.err` file. You can view this file by using the Amazon RDS console or by retrieving the log using the Amazon RDS API, Amazon RDS CLI, or AWS SDKs. The `<host-name>.err` file is flushed every 5 minutes, and its contents are appended to `mysql-error-running.log`. The `mysql-error-running.log` file is then rotated every hour and the hourly files generated during the last 24 hours are retained. Each log file has the hour it was generated (in UTC) appended to its name. The log files also have a timestamp that helps you determine when the log entries were written.

MariaDB writes to the error log only on startup, shutdown, and when it encounters errors. A DB instance can go hours or days without new entries being written to the error log. If you see no recent entries, it's because the server did not encounter an error that resulted in a log entry.

Accessing the MariaDB slow query and general logs

The MariaDB slow query log and the general log can be written to a file or a database table by setting parameters in your DB parameter group. For information about creating and modifying a DB parameter group, see [Working with DB parameter groups \(p. 228\)](#). You must set these parameters before you can view the slow query log or general log in the Amazon RDS console or by using the Amazon RDS API, AWS CLI, or AWS SDKs.

You can control MariaDB logging by using the parameters in this list:

- `slow_query_log`: To create the slow query log, set to 1. The default is 0.
- `general_log`: To create the general log, set to 1. The default is 0.
- `long_query_time`: To prevent fast-running queries from being logged in the slow query log, specify a value for the shortest query run time to be logged, in seconds. The default is 10 seconds; the minimum is 0. If `log_output = FILE`, you can specify a floating point value that goes to microsecond resolution. If `log_output = TABLE`, you must specify an integer value with second resolution. Only queries whose run time exceeds the `long_query_time` value are logged. For example, setting `long_query_time` to 0.1 prevents any query that runs for less than 100 milliseconds from being logged.
- `log_queries_not_using_indexes`: To log all queries that do not use an index to the slow query log, set this parameter to 1. The default is 0. Queries that do not use an index are logged even if their run time is less than the value of the `long_query_time` parameter.
- `log_output option`: You can specify one of the following options for the `log_output` parameter:
 - **TABLE** (default)– Write general queries to the `mysql.general_log` table, and slow queries to the `mysql.slow_log` table.
 - **FILE**– Write both general and slow query logs to the file system. Log files are rotated hourly.

- **NONE**—Disable logging.

When logging is enabled, Amazon RDS rotates table logs or deletes log files at regular intervals. This measure is a precaution to reduce the possibility of a large log file either blocking database use or affecting performance. **FILE** and **TABLE** logging approach rotation and deletion as follows:

- When **FILE** logging is enabled, log files are examined every hour and log files older than 24 hours are deleted. In some cases, the remaining combined log file size after the deletion might exceed the threshold of 2 percent of a DB instance's allocated space. In these cases, the largest log files are deleted until the log file size no longer exceeds the threshold.
- When **TABLE** logging is enabled, in some cases log tables are rotated every 24 hours. This rotation occurs if the space used by the table logs is more than 20 percent of the allocated storage space or the size of all logs combined is greater than 10 GB. If the amount of space used for a DB instance is greater than 90 percent of the DB instance's allocated storage space, then the thresholds for log rotation are reduced. Log tables are then rotated if the space used by the table logs is more than 10 percent of the allocated storage space or the size of all logs combined is greater than 5 GB.

When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If the backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the `mysql.general_log` table is named `mysql.general_log_backup`. The backup log table for the `mysql.slow_log` table is named `mysql.slow_log_backup`.

You can rotate the `mysql.general_log` table by calling the `mysql.rds_rotate_general_log` procedure. You can rotate the `mysql.slow_log` table by calling the `mysql.rds_rotate_slow_log` procedure.

Table logs are rotated during a database version upgrade.

Amazon RDS records both **TABLE** and **FILE** log rotation in an Amazon RDS event and sends you a notification.

To work with the logs from the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs, set the `log_output` parameter to **FILE**. Like the MariaDB error log, these log files are rotated hourly. The log files that were generated during the previous 24 hours are retained.

For more information about the slow query and general logs, go to the following topics in the MariaDB documentation:

- [Slow query log](#)
- [General query log](#)

Publishing MariaDB logs to Amazon CloudWatch Logs

You can configure your MariaDB DB instance to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

Amazon RDS publishes each MariaDB database log as a separate database stream in the log group. For example, if you configure the export function to include the slow query log, slow query data is stored in a slow query log stream in the `/aws/rds/instance/my_instance/slowquery` log group.

The error log is enabled by default. The following table summarizes the requirements for the other MariaDB logs.

Log	Requirement
Audit log	The DB instance must use a custom option group with the MARIADB_AUDIT_PLUGIN option.
General log	The DB instance must use a custom parameter group with the parameter setting general_log = 1 to enable the general log.
Slow query log	The DB instance must use a custom parameter group with the parameter setting slow_query_log = 1 to enable the slow query log.
Log output	The DB instance must use a custom parameter group with the parameter setting log_output = FILE to write logs to the file system and publish them to CloudWatch Logs.

Console

To publish MariaDB logs to CloudWatch Logs from the console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

You can publish a MariaDB logs with the AWS CLI. You can call the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

Note

A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish MariaDB logs by calling the following AWS CLI commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-from-s3`
- `restore-db-instance-to-point-in-time`

Run one of these AWS CLI commands with the following options:

- `--db-instance-identifier`

- --enable-cloudwatch-logs-exports
- --db-instance-class
- --engine

Other options might be required depending on the AWS CLI command you run.

Example

The following example modifies an existing MariaDB DB instance to publish log files to CloudWatch Logs. The --cloudwatch-logs-export-configuration value is a JSON object. The key for this object is EnableLogTypes, and its value is an array of strings with any combination of audit, error, general, and slowquery.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
  --db-instance-identifier mydbinstance \
  --cloudwatch-logs-export-configuration '{"EnableLogTypes": \
  ["audit", "error", "general", "slowquery"]}'
```

For Windows:

```
aws rds modify-db-instance ^
  --db-instance-identifier mydbinstance ^
  --cloudwatch-logs-export-configuration '{"EnableLogTypes": \
  ["audit", "error", "general", "slowquery"]}'
```

Example

The following command creates a MariaDB DB instance and publishes log files to CloudWatch Logs. The --enable-cloudwatch-logs-exports value is a JSON array of strings. The strings can be any combination of audit, error, general, and slowquery.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
  --db-instance-identifier mydbinstance \
  --enable-cloudwatch-logs-exports '[{"audit", "error", "general", "slowquery"}]' \
  --db-instance-class db.m4.large \
  --engine mariadb
```

For Windows:

```
aws rds create-db-instance ^
  --db-instance-identifier mydbinstance ^
  --enable-cloudwatch-logs-exports '[{"audit", "error", "general", "slowquery"}]' ^
  --db-instance-class db.m4.large ^
  --engine mariadb
```

RDS API

You can publish MariaDB logs with the RDS API. You can call the [ModifyDBInstance](#) operation with the following parameters:

- [DBInstanceIdentifier](#)
- [CloudwatchLogsExportConfiguration](#)

Note

A change to the [CloudwatchLogsExportConfiguration](#) parameter is always applied to the DB instance immediately. Therefore, the [ApplyImmediately](#) parameter has no effect.

You can also publish MariaDB logs by calling the following RDS API operations:

- [CreateDBInstance](#)
- [RestoreDBInstanceFromDBSnapshot](#)
- [RestoreDBInstanceFromS3](#)
- [RestoreDBInstanceToPointInTime](#)

Run one of these RDS API operations with the following parameters:

- [DBInstanceIdentifier](#)
- [EnableCloudwatchLogsExports](#)
- [Engine](#)
- [DBInstanceClass](#)

Other parameters might be required depending on the AWS CLI command you run.

Log file size

The MariaDB slow query log, error log, and the general log file sizes are constrained to no more than 2 percent of the allocated storage space for a DB instance. To maintain this threshold, logs are automatically rotated every hour and log files older than 24 hours are removed. If the combined log file size exceeds the threshold after removing old log files, then the largest log files are deleted until the log file size no longer exceeds the threshold.

Managing table-based MariaDB logs

You can direct the general and slow query logs to tables on the DB instance by creating a DB parameter group and setting the `log_output` server parameter to `TABLE`. General queries are then logged to the `mysql.general_log` table, and slow queries are logged to the `mysql.slow_log` table. You can query the tables to access the log information. Enabling this logging increases the amount of data written to the database, which can degrade performance.

Both the general log and the slow query logs are disabled by default. In order to enable logging to tables, you must also set the `general_log` and `slow_query_log` server parameters to 1.

Log tables keep growing until the respective logging activities are turned off by resetting the appropriate parameter to 0. A large amount of data often accumulates over time, which can use up a considerable percentage of your allocated storage space. Amazon RDS does not allow you to truncate the log tables, but you can move their contents. Rotating a table saves its contents to a backup table and then creates a new empty log table. You can manually rotate the log tables with the following command line procedures, where the command prompt is indicated by `PROMPT>`:

```
PROMPT> CALL mysql.rds_rotate_slow_log;
PROMPT> CALL mysql.rds_rotate_general_log;
```

To completely remove the old data and reclaim the disk space, call the appropriate procedure twice in succession.

Binary logging format

MariaDB on Amazon RDS supports the *row-based*, *statement-based*, and *mixed* binary logging formats. The default binary logging format is *mixed*. For details on the different MariaDB binary log formats, see [Binary log formats](#) in the MariaDB documentation.

If you plan to use replication, the binary logging format is important because it determines the record of data changes that is recorded in the source and sent to the replication targets. For information about the advantages and disadvantages of different binary logging formats for replication, see [Advantages and disadvantages of statement-based and row-based replication](#) in the MySQL documentation.

Important

Setting the binary logging format to row-based can result in very large binary log files. Large binary log files reduce the amount of storage available for a DB instance and can increase the amount of time to perform a restore operation of a DB instance.

Statement-based replication can cause inconsistencies between the source DB instance and a read replica. For more information, see [Unsafe statements for statement-based replication](#) in the MariaDB documentation.

To set the MariaDB binary logging format

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group that is used by the DB instance that you want to modify.

You can't modify a default parameter group. If the DB instance is using a default parameter group, create a new parameter group and associate it with the DB instance.

For more information on DB parameter groups, see [Working with DB parameter groups \(p. 228\)](#).

4. For **Parameter group actions**, choose **Edit**.
5. Set the `binlog_format` parameter to the binary logging format of your choice (**ROW**, **STATEMENT**, or **MIXED**).
6. Choose **Save changes** to save the updates to the DB parameter group.

Accessing MariaDB binary logs

You can use the `mysqlbinlog` utility to download binary logs in text format from MariaDB DB instances. The binary log is downloaded to your local computer. For more information about using the `mysqlbinlog` utility, go to [Using mysqlbinlog](#) in the MariaDB documentation.

To run the `mysqlbinlog` utility against an Amazon RDS instance, use the following options:

- Specify the `--read-from-remote-server` option.
- `--host`: Specify the DNS name from the endpoint of the instance.
- `--port`: Specify the port used by the instance.
- `--user`: Specify a MariaDB user that has been granted the replication slave permission.
- `--password`: Specify the password for the user, or omit a password value so the utility prompts you for a password.
- `--result-file`: Specify the local file that receives the output.
- Specify the names of one or more binary log files. To get a list of the available logs, use the SQL command `SHOW BINARY LOGS`.

For more information about mysqlbinlog options, go to [mysqlbinlog options](#) in the MariaDB documentation.

The following is an example:

For Linux, macOS, or Unix:

```
mysqlbinlog \
--read-from-remote-server \
--host=mariadbinstance1.1234abcd.region.rds.amazonaws.com \
--port=3306 \
--user ReplUser \
--password <password> \
--result-file=/tmp/binlog.txt
```

For Windows:

```
mysqlbinlog ^
--read-from-remote-server ^
--host=mariadbinstance1.1234abcd.region.rds.amazonaws.com ^
--port=3306 ^
--user ReplUser ^
--password <password> ^
--result-file=/tmp/binlog.txt
```

Amazon RDS normally purges a binary log as soon as possible, but the binary log must still be available on the instance to be accessed by mysqlbinlog. To specify the number of hours for RDS to retain binary logs, use the `mysql.rds_set_configuration` stored procedure and specify a period with enough time for you to download the logs. After you set the retention period, monitor storage usage for the DB instance to ensure that the retained binary logs do not take up too much storage.

The following example sets the retention period to 1 day:

```
call mysql.rds_set_configuration('binlog retention hours', 24);
```

To display the current setting, use the `mysql.rds_show_configuration` stored procedure:

```
call mysql.rds_show_configuration;
```

Binary log annotation

In a MariaDB DB instance, you can use the `Annotate_rows` event to annotate a row event with a copy of the SQL query that caused the row event. This approach provides similar functionality to enabling the `binlog_rows_query_log_events` parameter on a DB instance on MySQL version 5.6 or later.

You can enable binary log annotations globally by creating a custom parameter group and setting the `binlog_annotation_row_events` parameter to 1. You can also enable annotations at the session level, by calling `SET SESSION binlog_annotation_row_events = 1`. Use the `replicate_annotation_row_events` to replicate binary log annotations to the slave instance if binary logging is enabled on it. No special privileges are required to use these settings.

The following is an example of a row-based transaction in MariaDB. The use of row-based logging is triggered by setting the transaction isolation level to `read-committed`.

```
CREATE DATABASE IF NOT EXISTS test;
USE test;
CREATE TABLE square(x INT PRIMARY KEY, y INT NOT NULL) ENGINE = InnoDB;
```

```
SET SESSION TRANSACTION ISOLATION LEVEL READ COMMITTED;
BEGIN
INSERT INTO square(x, y) VALUES(5, 5 * 5);
COMMIT;
```

Without annotations, the binary log entries for the transaction look like the following:

```
BEGIN
/*!*/
# at 1163
# at 1209
#150922 7:55:57 server id 1855786460 end_log_pos 1209      Table_map: `test`.`square`
mapped to number 76
#150922 7:55:57 server id 1855786460 end_log_pos 1247      Write_rows: table id 76
flags: STMT_END_F
### INSERT INTO `test`.`square`
### SET
### @1=5
### @2=25
# at 1247
#150922 7:56:01 server id 1855786460 end_log_pos 1274      Xid = 62
COMMIT/*!*/;
```

The following statement enables session-level annotations for this same transaction, and disables them after committing the transaction:

```
CREATE DATABASE IF NOT EXISTS test;
USE test;
CREATE TABLE square(x INT PRIMARY KEY, y INT NOT NULL) ENGINE = InnoDB;
SET SESSION TRANSACTION ISOLATION LEVEL READ COMMITTED;
SET SESSION binlog_annotation_row_events = 1;
BEGIN;
INSERT INTO square(x, y) VALUES(5, 5 * 5);
COMMIT;
SET SESSION binlog_annotation_row_events = 0;
```

With annotations, the binary log entries for the transaction look like the following:

```
BEGIN
/*!*/
# at 423
# at 483
# at 529
#150922 8:04:24 server id 1855786460 end_log_pos 483 Annotate_rows:
#Q> INSERT INTO square(x, y) VALUES(5, 5 * 5)
#150922 8:04:24 server id 1855786460 end_log_pos 529 Table_map: `test`.`square` mapped
to number 76
#150922 8:04:24 server id 1855786460 end_log_pos 567 Write_rows: table id 76 flags:
STMT_END_F
### INSERT INTO `test`.`square`
### SET
### @1=5
### @2=25
# at 567
#150922 8:04:26 server id 1855786460 end_log_pos 594 Xid = 88
COMMIT/*!*/;
```

Microsoft SQL Server database log files

You can access Microsoft SQL Server error logs, agent logs, trace files, and dump files by using the Amazon RDS console, AWS CLI, or RDS API. For more information about viewing, downloading, and watching file-based database logs, see [Accessing Amazon RDS database log files \(p. 504\)](#).

Retention schedule

Log files are rotated each day and whenever your DB instance is restarted. The following is the retention schedule for Microsoft SQL Server logs on Amazon RDS.

Log type	Retention schedule
Error logs	A maximum of 30 error logs are retained. Amazon RDS might delete error logs older than 7 days.
Agent logs	A maximum of 10 agent logs are retained. Amazon RDS might delete agent logs older than 7 days.
Trace files	Trace files are retained according to the trace file retention period of your DB instance. The default trace file retention period is 7 days. To modify the trace file retention period for your DB instance, see Setting the retention period for trace and dump files (p. 824) .
Dump files	Dump files are retained according to the dump file retention period of your DB instance. The default dump file retention period is 7 days. To modify the dump file retention period for your DB instance, see Setting the retention period for trace and dump files (p. 824) .

Viewing the SQL Server error log by using the rds_read_error_log procedure

You can use the Amazon RDS stored procedure `rds_read_error_log` to view error logs and agent logs. For more information, see [Viewing error and agent logs \(p. 824\)](#).

Publishing SQL Server logs to Amazon CloudWatch Logs

With Amazon RDS for SQL Server, you can publish error and agent log events directly to Amazon CloudWatch Logs. Analyze the log data with CloudWatch Logs, then use CloudWatch to create alarms and view metrics.

With CloudWatch Logs, you can do the following:

- Store logs in highly durable storage space with a retention period that you define.
- Search and filter log data.
- Share log data between accounts.
- Export logs to Amazon S3.
- Stream data to Amazon Elasticsearch Service.
- Process log data in real time with Amazon Kinesis Data Streams.

Amazon RDS publishes each SQL Server database log as a separate database stream in the log group. For example, if you publish error logs, error data is stored in an error log stream in the `/aws/rds/instance/my_instance/error` log group.

Note

Publishing SQL Server logs to CloudWatch Logs isn't enabled by default. Publishing trace and dump files isn't supported. Publishing SQL Server logs to CloudWatch Logs is supported in all regions, except for Asia Pacific (Hong Kong).

Console

To publish SQL Server DB logs to CloudWatch Logs from the AWS Management Console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
You can choose **Agent log**, **Error log**, or both.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

To publish SQL Server logs, you can use the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

Note

A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish SQL Server logs using the following commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-to-point-in-time`

Example

The following example creates an SQL Server DB instance with CloudWatch Logs publishing enabled. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings that can include `error`, `agent`, or both.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--db-instance-identifier mydbinstance \
--enable-cloudwatch-logs-exports '[{"error", "agent"}]' \
--db-instance-class db.m4.large \
--engine sqlserver-se
```

For Windows:

```
aws rds create-db-instance ^
```

```
--db-instance-identifier mydbinstance ^
--enable-cloudwatch-logs-exports "[\"error\", \"agent\"]" ^
--db-instance-class db.m4.large ^
--engine sqlserver-se
```

Note

When using the Windows command prompt, you must escape double quotes ("") in JSON code by prefixing them with a backslash (\).

Example

The following example modifies an existing SQL Server DB instance to publish log files to CloudWatch Logs. The --cloudwatch-logs-export-configuration value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings that can include `error`, `agent`, or both.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--cloudwatch-logs-export-configuration '{"EnableLogTypes": ["error", "agent"]}'
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--cloudwatch-logs-export-configuration "{\"EnableLogTypes\": [\"error\", \"agent\"]}"
```

Note

When using the Windows command prompt, you must escape double quotes ("") in JSON code by prefixing them with a backslash (\).

Example

The following example modifies an existing SQL Server DB instance to disable publishing agent log files to CloudWatch Logs. The --cloudwatch-logs-export-configuration value is a JSON object. The key for this object is `DisableLogTypes`, and its value is an array of strings that can include `error`, `agent`, or both.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--cloudwatch-logs-export-configuration '{"DisableLogTypes": ["agent"]}'
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--cloudwatch-logs-export-configuration "{\"DisableLogTypes\": [\"agent\"]}"
```

Note

When using the Windows command prompt, you must escape double quotes ("") in JSON code by prefixing them with a backslash (\).

Accessing MySQL database log files

You can monitor the MySQL logs directly through the Amazon RDS console, Amazon RDS API, AWS CLI, or AWS SDKs. You can also access MySQL logs by directing the logs to a database table in the main database and querying that table. You can use the `mysqlbinlog` utility to download a binary log.

For more information about viewing, downloading, and watching file-based database logs, see [Accessing Amazon RDS database log files \(p. 504\)](#).

Topics

- [Overview of MySQL database logs \(p. 519\)](#)

- [Setting the binary logging format \(p. 524\)](#)
- [Accessing MySQL binary logs \(p. 525\)](#)

Overview of MySQL database logs

You can monitor the following types of MySQL log files:

- Error log
- Slow query log
- General log

The MySQL error log is generated by default. You can generate the slow query and general logs by setting parameters in your DB parameter group.

Log rotation and retention

The MySQL slow query log, error log, and the general log file sizes are constrained to no more than 2 percent of the allocated storage space for a DB instance. To maintain this threshold, logs are automatically rotated every hour. MySQL removes log files more than two weeks old. If the combined log file size exceeds the threshold after removing old log files, then the oldest log files are deleted until the log file size no longer exceeds the threshold.

Size limits on BLOBs

For MySQL, there is a size limit on BLOBs written to the redo log. To account for this limit, ensure that the `innodb_log_file_size` parameter for your MySQL DB instance is 10 times larger than the largest BLOB data size found in your tables, plus the length of other variable length fields (`VARCHAR`, `VARBINARY`, `TEXT`) in the same tables. For information on how to set parameter values, see [Working with DB parameter groups \(p. 228\)](#). For information on the redo log BLOB size limit, go to [Changes in MySQL 5.6.20](#).

Accessing MySQL error logs

MySQL writes errors in the `mysql-error.log` file. Each log file has the hour it was generated (in UTC) appended to its name. The log files also have a timestamp that helps you determine when the log entries were written.

MySQL writes to the error log only on startup, shutdown, and when it encounters errors. A DB instance can go hours or days without new entries being written to the error log. If you see no recent entries, it's because the server did not encounter an error that would result in a log entry.

MySQL writes `mysql-error.log` to disk every 5 minutes. MySQL appends the contents of the log to `mysql-error-running.log`.

MySQL rotates the `mysql-error-running.log` file every hour. RDS for MySQL retains the logs generated during the last two weeks.

Note

The log retention period is different between Amazon RDS and Aurora.

Accessing the MySQL slow query and general logs

The MySQL slow query log and the general log can be written to a file or a database table by setting parameters in your DB parameter group. For information about creating and modifying a DB parameter group, see [Working with DB parameter groups \(p. 228\)](#). You must set these parameters before you can view the slow query log or general log in the Amazon RDS console or by using the Amazon RDS API, Amazon RDS CLI, or AWS SDKs.

You can control MySQL logging by using the parameters in this list:

- `slow_query_log`: To create the slow query log, set to 1. The default is 0.
- `general_log`: To create the general log, set to 1. The default is 0.
- `long_query_time`: To prevent fast-running queries from being logged in the slow query log, specify a value for the shortest query run time to be logged, in seconds. The default is 10 seconds; the minimum is 0. If `log_output = FILE`, you can specify a floating point value that goes to microsecond resolution. If `log_output = TABLE`, you must specify an integer value with second resolution. Only queries whose run time exceeds the `long_query_time` value are logged. For example, setting `long_query_time` to 0.1 prevents any query that runs for less than 100 milliseconds from being logged.
- `log_queries_not_using_indexes`: To log all queries that do not use an index to the slow query log, set to 1. The default is 0. Queries that do not use an index are logged even if their run time is less than the value of the `long_query_time` parameter.
- `log_output option`: You can specify one of the following options for the `log_output` parameter.
 - **TABLE** (default) – Write general queries to the `mysql.general_log` table, and slow queries to the `mysql.slow_log` table.
 - **FILE** – Write both general and slow query logs to the file system. Log files are rotated hourly.
 - **NONE** – Disable logging.

When logging is enabled, Amazon RDS rotates table logs or deletes log files at regular intervals. This measure is a precaution to reduce the possibility of a large log file either blocking database use or affecting performance. `FILE` and `TABLE` logging approach rotation and deletion as follows:

- When `FILE` logging is enabled, log files are examined every hour and log files more than two weeks old are deleted. In some cases, the remaining combined log file size after the deletion might exceed the threshold of 2 percent of a DB instance's allocated space. In these cases, the largest log files are deleted until the log file size no longer exceeds the threshold.
- When `TABLE` logging is enabled, in some cases log tables are rotated every 24 hours. This rotation occurs if the space used by the table logs is more than 20 percent of the allocated storage space or the size of all logs combined is greater than 10 GB. If the amount of space used for a DB instance is greater than 90 percent of the DB instance's allocated storage space, then the thresholds for log rotation are reduced. Log tables are then rotated if the space used by the table logs is more than 10 percent of

the allocated storage space or the size of all logs combined is greater than 5 GB. You can subscribe to the `low_free_storage` event to be notified when log tables are rotated to free up space. For more information, see [Using Amazon RDS event notification \(p. 487\)](#).

When log tables are rotated, the current log table is copied to a backup log table and the entries in the current log table are removed. If the backup log table already exists, then it is deleted before the current log table is copied to the backup. You can query the backup log table if needed. The backup log table for the `mysql.general_log` table is named `mysql.general_log_backup`. The backup log table for the `mysql.slow_log` table is named `mysql.slow_log_backup`.

You can rotate the `mysql.general_log` table by calling the `mysql.rds_rotate_general_log` procedure. You can rotate the `mysql.slow_log` table by calling the `mysql.rds_rotate_slow_log` procedure.

Table logs are rotated during a database version upgrade.

To work with the logs from the Amazon RDS console, Amazon RDS API, Amazon RDS CLI, or AWS SDKs, set the `log_output` parameter to `FILE`. Like the MySQL error log, these log files are rotated hourly. The log files that were generated during the previous two weeks are retained. Note that the retention period is different between Amazon RDS and Aurora.

For more information about the slow query and general logs, go to the following topics in the MySQL documentation:

- [The slow query log](#)
- [The general query log](#)

Accessing the MySQL audit log

To access the audit log, the DB instance must use a custom option group with the `MARIADB_AUDIT_PLUGIN` option. For more information, see [MariaDB Audit Plugin support \(p. 926\)](#).

Publishing MySQL logs to Amazon CloudWatch Logs

You can configure your MySQL DB instance to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

Amazon RDS publishes each MySQL database log as a separate database stream in the log group. For example, if you configure the export function to include the slow query log, slow query data is stored in a slow query log stream in the `/aws/rds/instance/my_instance/slowquery` log group.

The error log is enabled by default. The following table summarizes the requirements for the other MySQL logs.

Log	Requirement
Audit log	The DB instance must use a custom option group with the <code>MARIADB_AUDIT_PLUGIN</code> option.
General log	The DB instance must use a custom parameter group with the parameter setting <code>general_log = 1</code> to enable the general log.

Log	Requirement
Slow query log	The DB instance must use a custom parameter group with the parameter setting <code>slow_query_log = 1</code> to enable the slow query log.
Log output	The DB instance must use a custom parameter group with the parameter setting <code>log_output = FILE</code> to write logs to the file system and publish them to CloudWatch Logs.

Note

Publishing log files to CloudWatch Logs is only supported for MySQL versions 5.6, 5.7, and 8.0.

Console

To publish MySQL logs to CloudWatch Logs using the console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

You can publish MySQL logs with the AWS CLI. You can call the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

Note

A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish MySQL logs by calling the following AWS CLI commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-from-s3`
- `restore-db-instance-to-point-in-time`

Run one of these AWS CLI commands with the following options:

- `--db-instance-identifier`
- `--enable-cloudwatch-logs-exports`
- `--db-instance-class`

- `--engine`

Other options might be required depending on the AWS CLI command you run.

Example

The following example modifies an existing MySQL DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes": \
    ["audit", "error", "general", "slowquery"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration '{"EnableLogTypes": \
    ["audit", "error", "general", "slowquery"]}'
```

Example

The following example creates a MySQL DB instance and publishes log files to CloudWatch Logs. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings. The strings can be any combination of `audit`, `error`, `general`, and `slowquery`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --enable-cloudwatch-logs-exports '[{"audit", "error", "general", "slowquery"}]' \
    --db-instance-class db.m4.large \
    --engine MySQL
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --enable-cloudwatch-logs-exports '[{"audit", "error", "general", "slowquery"}]' ^
    --db-instance-class db.m4.large ^
    --engine MySQL
```

RDS API

You can publish MySQL logs with the RDS API. You can call the `ModifyDBInstance` action with the following parameters:

- `DBInstanceIdentifier`
- `CloudwatchLogsExportConfiguration`

Note

A change to the `CloudwatchLogsExportConfiguration` parameter is always applied to the DB instance immediately. Therefore, the `ApplyImmediately` parameter has no effect.

You can also publish MySQL logs by calling the following RDS API operations:

- [CreateDBInstance](#)
- [RestoreDBInstanceFromDBSnapshot](#)
- [RestoreDBInstanceFromS3](#)
- [RestoreDBInstanceToPointInTime](#)

Run one of these RDS API operations with the following parameters:

- `DBInstanceIdentifier`
- `EnableCloudwatchLogsExports`
- `Engine`
- `DBInstanceClass`

Other parameters might be required depending on the AWS CLI command you run.

Managing table-based MySQL logs

You can direct the general and slow query logs to tables on the DB instance by creating a DB parameter group and setting the `log_output` server parameter to `TABLE`. General queries are then logged to the `mysql.general_log` table, and slow queries are logged to the `mysql.slow_log` table. You can query the tables to access the log information. Enabling this logging increases the amount of data written to the database, which can degrade performance.

Both the general log and the slow query logs are disabled by default. In order to enable logging to tables, you must also set the `general_log` and `slow_query_log` server parameters to 1.

Log tables keep growing until the respective logging activities are turned off by resetting the appropriate parameter to 0. A large amount of data often accumulates over time, which can use up a considerable percentage of your allocated storage space. Amazon RDS does not allow you to truncate the log tables, but you can move their contents. Rotating a table saves its contents to a backup table and then creates a new empty log table. You can manually rotate the log tables with the following command line procedures, where the command prompt is indicated by `PROMPT>`:

```
PROMPT> CALL mysql.rds_rotate_slow_log;
PROMPT> CALL mysql.rds_rotate_general_log;
```

To completely remove the old data and reclaim the disk space, call the appropriate procedure twice in succession.

Setting the binary logging format

MySQL on Amazon RDS supports the *row-based*, *statement-based*, and *mixed* binary logging formats for MySQL version 5.6 and later. The default binary logging format is mixed. For DB instances running MySQL versions 5.1 and 5.5, only mixed binary logging is supported. For details on the different MySQL binary log formats, see [Binary logging formats](#) in the MySQL documentation.

If you plan to use replication, the binary logging format is important because it determines the record of data changes that is recorded in the source and sent to the replication targets. For information about the advantages and disadvantages of different binary logging formats for replication, see [Advantages and disadvantages of statement-based and row-based replication](#) in the MySQL documentation.

Important

Setting the binary logging format to row-based can result in very large binary log files. Large binary log files reduce the amount of storage available for a DB instance and can increase the amount of time to perform a restore operation of a DB instance.

Statement-based replication can cause inconsistencies between the source DB instance and a read replica. For more information, see [Determination of safe and unsafe statements in binary logging](#) in the MySQL documentation.

To set the MySQL binary logging format

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group used by the DB instance you want to modify.

You can't modify a default parameter group. If the DB instance is using a default parameter group, create a new parameter group and associate it with the DB instance.

For more information on parameter groups, see [Working with DB parameter groups \(p. 228\)](#).

4. From **Parameter group actions**, choose **Edit**.
5. Set the `binlog_format` parameter to the binary logging format of your choice (**ROW**, **STATEMENT**, or **MIXED**).
6. Choose **Save changes** to save the updates to the DB parameter group.

Important

Changing a DB parameter group affects all DB instances that use that parameter group. If you want to specify different binary logging formats for different MySQL DB instances in an AWS Region, the DB instances must use different DB parameter groups. These parameter groups identify different logging formats. Assign the appropriate DB parameter group to the each DB instance.

Accessing MySQL binary logs

You can use the `mysqlbinlog` utility to download or stream binary logs from Amazon RDS instances running MySQL 5.6 or later. The binary log is downloaded to your local computer, where you can perform actions such as replaying the log using the `mysql` utility. For more information about using the `mysqlbinlog` utility, go to [Using mysqlbinlog to back up binary log files](#).

To run the `mysqlbinlog` utility against an Amazon RDS instance, use the following options:

- Specify the `--read-from-remote-server` option.
- `--host`: Specify the DNS name from the endpoint of the instance.
- `--port`: Specify the port used by the instance.
- `--user`: Specify a MySQL user that has been granted the replication slave permission.
- `--password`: Specify the password for the user, or omit a password value so that the utility prompts you for a password.
- To have the file downloaded in binary format, specify the `--raw` option.
- `--result-file`: Specify the local file to receive the raw output.
- Specify the names of one or more binary log files. To get a list of the available logs, use the SQL command `SHOW BINARY LOGS`.
- To stream the binary log files, specify the `--stop-never` option.

For more information about `mysqlbinlog` options, go to [mysqlbinlog - utility for processing binary log files](#).

For example, see the following.

For Linux, macOS, or Unix:

```
mysqlbinlog \
--read-from-remote-server \
--host=MySQL56Instance1.cg034hpkmmt.region.rds.amazonaws.com \
--port=3306 \
--user ReplUser \
--password \
--raw \
--result-file=/tmp/ \
binlog.00098
```

For Windows:

```
mysqlbinlog ^
--read-from-remote-server ^
--host=MySQL56Instance1.cg034hpkmmt.region.rds.amazonaws.com ^
--port=3306 ^
--user ReplUser ^
--password ^
--raw ^
--result-file=/tmp/ ^
binlog.00098
```

Amazon RDS normally purges a binary log as soon as possible, but the binary log must still be available on the instance to be accessed by mysqlbinlog. To specify the number of hours for RDS to retain binary logs, use the `mysql.rds_set_configuration` stored procedure and specify a period with enough time for you to download the logs. After you set the retention period, monitor storage usage for the DB instance to ensure that the retained binary logs don't take up too much storage.

Note

The `mysql.rds_set_configuration` stored procedure is only available for MySQL version 5.6 or later.

The following example sets the retention period to 1 day.

```
call mysql.rds_set_configuration('binlog retention hours', 24);
```

To display the current setting, use the `mysql.rds_show_configuration` stored procedure.

```
call mysql.rds_show_configuration;
```

Oracle database log files

You can access Oracle alert logs, audit files, and trace files by using the Amazon RDS console or API. For more information about viewing, downloading, and watching file-based database logs, see [Accessing Amazon RDS database log files \(p. 504\)](#).

The Oracle audit files provided are the standard Oracle auditing files. Amazon RDS supports the Oracle fine-grained auditing (FGA) feature. However, log access doesn't provide access to FGA events that are stored in the `SYS.FGA_LOG$` table and that are accessible through the `DBA_FGA_AUDIT_TRAIL` view.

The `DescribeDBLogFiles` API operation that lists the Oracle log files that are available for a DB instance ignores the `MaxRecords` parameter and returns up to 1,000 records. The call returns `LastWritten` as a POSIX date in milliseconds.

Retention schedule

The Oracle database engine might rotate log files if they get very large. To retain audit or trace files, download them. If you store the files locally, you reduce your Amazon RDS storage costs and make more space available for your data.

The following table shows the retention schedule for Oracle alert logs, audit files, and trace files on Amazon RDS.

Log type	Retention schedule
Alert logs	The text alert log is rotated daily with 30-day retention managed by Amazon RDS. The XML alert log is retained for at least seven days. You can access this log by using the <code>ALERTLOG</code> view.
Audit files	The default retention period for audit files is seven days. Amazon RDS might delete audit files older than seven days.
Trace files	The default retention period for trace files is seven days. Amazon RDS might delete trace files older than seven days.
Listener logs	The default retention period for the listener logs is seven days. Amazon RDS might delete listener logs older than seven days.

Note

Audit files and trace files share the same retention configuration.

Working with Oracle trace files

Following, you can find descriptions of Amazon RDS procedures to create, refresh, access, and delete trace files.

Listing files

You can use either of two procedures to allow access to any file in the `background_dump_dest` path. The first procedure refreshes a view containing a listing of all files currently in `background_dump_dest`.

```
EXEC rdsadmin.manage_tracefiles.refresh_tracefile_listing;
```

After the view is refreshed, query the following view to access the results.

```
SELECT * FROM rdsadmin.tracefile_listing;
```

An alternative to the previous process is to use `FROM table` to stream nonrelational data in a table-like format to list database directory contents.

```
SELECT * FROM TABLE(rdsadmin.rds_file_util.listdir('BDUMP'));
```

The following query shows the text of a log file.

```
SELECT text FROM
  TABLE(rdsadmin.rds_file_util.read_text_file('BDUMP','alert_dbname.log.date'));
```

On a read replica, get the name of the BDUMP directory by querying `V$DATABASE.DB_UNIQUE_NAME`. If the unique name is `DATABASE_B`, then the BDUMP directory is `BDUMP_B`. The following example queries the BDUMP name on a replica and then uses this name to query the contents of `alert_DATABASE.log.2020-06-23`.

```
SELECT 'BDUMP' || (SELECT regexp_replace(DB_UNIQUE_NAME,'.*([A-Z])','\1') FROM V
$DATABASE) AS BDUMP_VARIABLE FROM DUAL;

BDUMP_VARIABLE
-----
BDUMP_B

SELECT TEXT FROM
  table(rdsadmin.rds_file_util.read_text_file('BDUMP_B','alert_DATABASE.log.2020-06-23'));
```

Generating trace files and tracing a session

Because there are no restrictions on `ALTER SESSION`, many standard methods to generate trace files in Oracle remain available to an Amazon RDS DB instance. The following procedures are provided for trace files that require greater access.

Oracle method	Amazon RDS method
<code>oradebug hanganalyze 3</code>	<code>EXEC rdsadmin.manage_tracefiles.hanganalyze;</code>
<code>oradebug dump systemstate 266</code>	<code>EXEC rdsadmin.manage_tracefiles.dump_systemstate;</code>

You can use many standard methods to trace individual sessions connected to an Oracle DB instance in Amazon RDS. To enable tracing for a session, you can run subprograms in PL/SQL packages supplied by Oracle, such as `DBMS_SESSION` and `DBMS_MONITOR`. For more information, see [Enabling tracing for a session](#) in the Oracle documentation.

Retrieving trace files

You can retrieve any trace file in `background_dump_dest` using a standard SQL query on an Amazon RDS-managed external table. To use this method, you must execute the procedure to set the location for this table to the specific trace file.

For example, you can use the `rdsadmin.tracefile_listing` view mentioned preceding to list all of the trace files on the system. You can then set the `tracefile_table` view to point to the intended trace file using the following procedure.

```
EXEC
rdsadmin.manage_tracefiles.set_tracefile_table_location('CUST01_ora_3260_SYSTEMSTATE.trc');
```

The following example creates an external table in the current schema with the location set to the file provided. You can retrieve the contents into a local file using a SQL query.

```
SPOOL /tmp/tracefile.txt
SELECT * FROM tracefile_table;
SPOOL OFF;
```

Purging trace files

Trace files can accumulate and consume disk space. Amazon RDS purges trace files by default and log files that are older than seven days. You can view and set the trace file retention period using the `show_configuration` procedure. You should run the command `SET SERVEROUTPUT ON` so that you can view the configuration results.

The following example shows the current trace file retention period, and then sets a new trace file retention period.

```
# Show the current tracefile retention
SQL> EXEC rdsadmin.rdsadmin_util.show_configuration;
NAME:tracefile retention
VALUE:10080
DESCRIPTION:tracefile expiration specifies the duration in minutes before tracefiles in
bdump are automatically deleted.

# Set the tracefile retention to 24 hours:
SQL> EXEC rdsadmin.rdsadmin_util.set_configuration('tracefile retention',1440);

#show the new tracefile retention
SQL> EXEC rdsadmin.rdsadmin_util.show_configuration;
NAME:tracefile retention
VALUE:1440
DESCRIPTION:tracefile expiration specifies the duration in minutes before tracefiles in
bdump are automatically deleted.
```

In addition to the periodic purge process, you can manually remove files from the `background_dump_dest`. The following example shows how to purge all files older than five minutes.

```
EXEC rdsadmin.manage_tracefiles.purge_tracefiles(5);
```

You can also purge all files that match a specific pattern (if you do, don't include the file extension, such as .trc). The following example shows how to purge all files that start with `SCHPOC1_ora_5935`.

```
EXEC rdsadmin.manage_tracefiles.purge_tracefiles('SCHPOC1_ora_5935');
```

Publishing Oracle logs to Amazon CloudWatch Logs

You can configure your Amazon RDS for Oracle DB instance to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can analyze the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage.

Amazon RDS publishes each Oracle database log as a separate database stream in the log group. For example, if you configure the export function to include the audit log, audit data is stored in an audit

log stream in the `/aws/rds/instance/my_instance/audit` log group. RDS for Oracle supports the following logs:

- Alert log
- Trace log
- Audit log
- Listener log
- Oracle Management Agent log

This Oracle Management Agent log consists of the log streams shown in the following table.

Log name	CloudWatch log stream
<code>emctl.log</code>	<code>oemagent-emctl</code>
<code>emdctlj.log</code>	<code>oemagent-emdctlj</code>
<code>gcagent.log</code>	<code>oemagent-gcagent</code>
<code>gcagent_errors.log</code>	<code>oemagent-gcagent-errors</code>
<code>emagent.nohup</code>	<code>oemagent-emagent-nohup</code>
<code>secure.log</code>	<code>oemagent-secure</code>

For more information, see [Locating Management Agent Log and Trace Files](#) in the Oracle documentation.

Console

To publish Oracle DB logs to CloudWatch Logs from the AWS Management Console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**, and then choose the DB instance that you want to modify.
3. Choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.
5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

To publish Oracle logs, you can use the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`
- `--cloudwatch-logs-export-configuration`

Note

A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish Oracle logs using the following commands:

- `create-db-instance`

- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-from-s3`
- `restore-db-instance-to-point-in-time`

Example

The following example creates an Oracle DB instance with CloudWatch Logs publishing enabled. The `--cloudwatch-logs-export-configuration` value is a JSON array of strings. The strings can be any combination of alert, audit, listener, and trace.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration
    '[["trace","audit","alert","listener","oemagent"]]' \
    --db-instance-class db.m5.large \
    --allocated-storage 20 \
    --engine oracle-ee \
    --engine-version 12.1.0.2.v18 \
    --license-model bring-your-own-license \
    --master-username myadmin \
    --master-user-password mypassword
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration trace alert audit listener oemagent ^
    --db-instance-class db.m5.large ^
    --allocated-storage 20 ^
    --engine oracle-ee ^
    --engine-version 12.1.0.2.v18 ^
    --license-model bring-your-own-license ^
    --master-username myadmin ^
    --master-user-password mypassword
```

Example

The following example modifies an existing Oracle DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of alert, audit, listener, and trace.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"EnableLogTypes":'
    ['trace','alert','audit','listener','oemagent']}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration EnableLogTypes=\"trace\","alert\","audit\",
    "listener\","oemagent\"
```

Example

The following example modifies an existing Oracle DB instance to disable publishing audit and listener log files to CloudWatch Logs. The --cloudwatch-logs-export-configuration value is a JSON object. The key for this object is DisableLogTypes, and its value is an array of strings with any combination of alert, audit, listener, and trace.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --cloudwatch-logs-export-configuration '{"DisableLogTypes":["audit","listener"]}'
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --cloudwatch-logs-export-configuration DisableLogTypes=\"audit\",\"listener\"
```

RDS API

You can publish Oracle DB logs with the RDS API. You can call the [ModifyDBInstance](#) action with the following parameters:

- `DBInstanceIdentifier`
- `CloudwatchLogsExportConfiguration`

Note

A change to the `CloudwatchLogsExportConfiguration` parameter is always applied to the DB instance immediately. Therefore, the `ApplyImmediately` parameter has no effect.

You can also publish Oracle logs by calling the following RDS API operations:

- [CreateDBInstance](#)
- [RestoreDBInstanceFromDBSnapshot](#)
- [RestoreDBInstanceFromS3](#)
- [RestoreDBInstanceToPointInTime](#)

Run one of these RDS API operations with the following parameters:

- `DBInstanceIdentifier`
- `EnableCloudwatchLogsExports`
- `Engine`
- `DBInstanceClass`

Other parameters might be required depending on the RDS operation that you run.

Previous methods for accessing alert logs and listener logs

You can view the alert log using the Amazon RDS console. You can also use the following SQL statement to access the alert log.

```
SELECT message_text FROM alertlog;
```

The `listenerlog` view contains entries for Oracle Database version 12.1.0.2 and earlier. To access the listener log for these database versions, use the following query.

```
SELECT message_text FROM listenerlog;
```

For Oracle Database versions 12.2.0.1 and later, access the listener log using Amazon CloudWatch Logs.

Note

Oracle rotates the alert and listener logs when they exceed 10 MB, at which point they are unavailable from Amazon RDS views.

PostgreSQL database log files

Amazon RDS PostgreSQL generates query and error logs. You can use log messages to troubleshoot performance and auditing issues while using the database.

To view, download, and watch file-based database logs, see [Accessing Amazon RDS database log files \(p. 504\)](#).

Topics

- [Overview of PostgreSQL logs \(p. 534\)](#)
- [Setting the log retention period \(p. 535\)](#)
- [Setting the message format \(p. 535\)](#)
- [Enabling query logging \(p. 535\)](#)
- [Publishing PostgreSQL logs to Amazon CloudWatch Logs \(p. 537\)](#)

Overview of PostgreSQL logs

PostgreSQL generates event log files that contain useful information for DBAs.

Log contents

The default logging level captures errors that affect your server. By default, Amazon RDS PostgreSQL logging parameters capture all server errors, including the following:

- Query failures
- Login failures
- Fatal server errors
- Deadlocks

To identify application issues, you can use the preceding error messages. For example, if you converted a legacy application from Oracle to Amazon RDS PostgreSQL, some queries may not convert correctly. These incorrectly formatted queries generate error messages in the logs, which you can use to identify the problematic code.

You can modify PostgreSQL logging parameters to capture additional information, including the following:

- Connections and disconnections
- Checkpoints
- Schema modification queries
- Queries waiting for locks
- Queries consuming temporary disk storage
- Backend autovacuum process consuming resources

The preceding log information can help troubleshoot potential performance and auditing issues. For more information, see [Error reporting and logging](#) in the PostgreSQL documentation. For a useful AWS blog about PostgreSQL logging, see [Working with RDS and Aurora PostgreSQL logs: Part 1](#) and [Working with RDS and Aurora PostgreSQL logs: Part 2](#).

Parameter groups

Each Amazon RDS PostgreSQL instance is associated with a *parameter group* that contains the engine specific configurations. The engine configurations also include several parameters that control

PostgreSQL logging behavior. AWS provides the parameter groups with default configuration settings to use for your instances. However, to change the default settings, you must create a clone of the default parameter group, modify it, and attach it to your instance.

To set logging parameters for a DB instance, set the parameters in a DB parameter group and associate that parameter group with the DB instance. For more information, see [Working with DB parameter groups \(p. 228\)](#).

Setting the log retention period

To set the retention period for system logs, use the `rds.log_retention_period` parameter. You can find `rds.log_retention_period` in the DB parameter group associated with your DB instance. The unit for this parameter is minutes. For example, a setting of 1,440 retains logs for one day. The default value is 4,320 (three days). The maximum value is 10,080 (seven days). Your instance must have enough allocated storage to contain the retained log files.

To retain older logs, publish them to Amazon CloudWatch Logs. For more information, see [Publishing PostgreSQL logs to Amazon CloudWatch Logs \(p. 537\)](#).

Setting the message format

By default, Amazon RDS PostgreSQL generates logs in standard error (stderr) format. In this format, each log message is prefixed with the information specified by the parameter `log_line_prefix`. Amazon RDS only allows the following value for `log_line_prefix`:

```
%t:%r:%u@%d:[%p]:t
```

The preceding value maps to the following code:

```
log-time : remote-host : user-name @ db-name : [ process-id ]
```

For example, the following error message results from querying a column using the wrong name.

```
2019-03-10 03:54:59 UTC:10.0.0.123(52834):postgres@tstldb:[20175]:ERROR: column "wrong" does not exist at character 8
```

To specify the format for output logs, use the parameter `log_destination`. To make the instance generate both standard and CSV output files, set `log_destination` to `csvlog` in your instance parameter group. For a discussion of PostgreSQL logs, see [Working with RDS and Aurora PostgreSQL logs: Part 1](#).

Enabling query logging

To enable query logging for your PostgreSQL DB instance, set two parameters in the DB parameter group associated with your DB instance: `log_statement` and `log_min_duration_statement`.

The `log_statement` parameter controls which SQL statements are logged. The default value is `none`. We recommend that when you debug issues in your DB instance, set this parameter to `all` to log all statements. To log all data definition language (DDL) statements (CREATE, ALTER, DROP, and so on), set this value to `ddl`. To log all DDL and data modification language (DML) statements (INSERT, UPDATE, DELETE, and so on), set the value to `mod`.

Warning

Sensitive information such as passwords can be exposed if you set the `log_statement` parameter to `ddl`, `mod`, or `all`. To avoid this risk, set the `log_statement` to `none`. Also consider the following solutions:

- Encrypt the sensitive information on the client side and use the `ENCRYPTED` and `UNENCRYPTED` options of the `CREATE` and `ALTER` statements.
- Restrict access to the CloudWatch logs.
- Use stronger authentication mechanisms such as IAM.

For auditing, you can use the PostgreSQL pgAudit extension because it redacts the sensitive information for `CREATE` and `ALTER` commands.

The `log_min_duration_statement` parameter sets the limit in milliseconds of a statement to be logged. All SQL statements that run longer than the parameter setting are logged. This parameter is disabled and set to -1 by default. Enabling this parameter can help you find unoptimized queries.

To set up query logging, take the following steps:

1. Set the `log_statement` parameter to `all`. The following example shows the information that is written to the `postgres.log` file.

```
2013-11-05 16:48:56 UTC::@[2952]:LOG: received SIGHUP, reloading configuration files
2013-11-05 16:48:56 UTC::@[2952]:LOG: parameter "log_statement" changed to "all"
```

Additional information is written to the `postgres.log` file when you run a query. The following example shows the type of information written to the file after a query.

```
2013-11-05 16:41:07 UTC::@[2955]:LOG: checkpoint starting: time
2013-11-05 16:41:07 UTC::@[2955]:LOG: checkpoint complete: wrote 1 buffers (0.3%); 
0 transaction log file(s) added, 0 removed, 1 recycled; write=0.000 s, sync=0.003 s
total=0.012 s; sync files=1, longest=0.003 s, average=0.003 s
2013-11-05 16:45:14 UTC:[local]:master@postgres:[8839]:LOG: statement: SELECT d.datname
as "Name",
    pg_catalog.pg_get_userbyid(d.datdba) as "Owner",
    pg_catalog.pg_encoding_to_char(d.encoding) as "Encoding",
    d.datcollate as "Collate",
    d.datctype as "Ctype",
    pg_catalog.array_to_string(d.datacl, E'\n') AS "Access privileges"
FROM pg_catalog.pg_database d
ORDER BY 1;
2013-11-05 16:45:
```

2. Set the `log_min_duration_statement` parameter. The following example shows the information that is written to the `postgres.log` file when the parameter is set to 1.

```
2013-11-05 16:48:56 UTC::@[2952]:LOG: received SIGHUP, reloading configuration files
2013-11-05 16:48:56 UTC::@[2952]:LOG: parameter "log_min_duration_statement" changed to
"1"
```

Additional information is written to the `postgres.log` file when you run a query that exceeds the duration parameter setting. The following example shows the type of information written to the file after a query.

```
2013-11-05 16:51:10 UTC:[local]:master@postgres:[9193]:LOG: statement: SELECT
c2.relname, i.indisprimary, i.indisunique, i.indisclustered, i.indisvalid,
pg_catalog.pg_get_indexdef(i.indexrelid, 0, true),
    pg_catalog.pg_get_constraintdef(con.oid, true), contype, condeferrable, condeferred,
c2.reltablename
FROM pg_catalog.pg_class c, pg_catalog.pg_class c2, pg_catalog.pg_index i
    LEFT JOIN pg_catalog.pg_constraint con ON (conrelid = i.indrelid AND conindid =
i.indexrelid AND contype IN ('p','u','x'))
WHERE c.oid = '1255' AND c.oid = i.indrelid AND i.indexrelid = c2.oid
```

```
ORDER BY i.indisprimary DESC, i.indisunique DESC, c2.relname;
2013-11-05 16:51:10 UTC:[local]:master@postgres:[9193]:LOG: duration: 3.367 ms
2013-11-05 16:51:10 UTC:[local]:master@postgres:[9193]:LOG: statement: SELECT
c.oid::pg_catalog.regclass FROM pg_catalog.pg_class c, pg_catalog.pg_inherits i WHERE
c.oid=i.inhparent AND i.inhrelid = '1255' ORDER BY inhseqno;
2013-11-05 16:51:10 UTC:[local]:master@postgres:[9193]:LOG: duration: 1.002 ms
2013-11-05 16:51:10 UTC:[local]:master@postgres:[9193]:LOG: statement:
SELECT c.oid::pg_catalog.regclass FROM pg_catalog.pg_class c,
pg_catalog.pg_inherits i WHERE c.oid=i.inhrelid AND i.inhparent = '1255' ORDER BY
c.oid::pg_catalog.regclass::pg_catalog.text;
2013-11-05 16:51:18 UTC:[local]:master@postgres:[9193]:LOG: statement: select proname
from pg_proc;
2013-11-05 16:51:18 UTC:[local]:master@postgres:[9193]:LOG: duration: 3.469 ms
```

Publishing PostgreSQL logs to Amazon CloudWatch Logs

To store your PostgreSQL log records in highly durable storage, you can use Amazon CloudWatch Logs. With CloudWatch Logs, you can also perform real-time analysis of log data and use CloudWatch to view metrics and create alarms. For example, if you set `log_statements` to `ddl`, you can set up an alarm to alert whenever a DDL statement is executed.

To work with CloudWatch Logs, configure your RDS for PostgreSQL DB instance to publish log data to a log group.

Note

Publishing log files to CloudWatch Logs is supported only for PostgreSQL versions 9.6.6 and later and 10.4 and later.

You can publish the following log types to CloudWatch Logs for RDS for PostgreSQL:

- Postgresql log
- Upgrade log (not available for Aurora PostgreSQL)

After you complete the configuration, Amazon RDS publishes the log events to log streams within a CloudWatch log group. For example, the PostgreSQL log data is stored within the log group `/aws/rds/instance/my_instance/postgresql`. To view your logs, open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.

Console

To publish PostgreSQL logs to CloudWatch Logs using the console

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the DB instance that you want to modify, and then choose **Modify**.
4. In the **Log exports** section, choose the logs that you want to start publishing to CloudWatch Logs.

The **Log exports** section is available only for PostgreSQL versions that support publishing to CloudWatch Logs.

5. Choose **Continue**, and then choose **Modify DB Instance** on the summary page.

AWS CLI

You can publish PostgreSQL logs with the AWS CLI. You can call the `modify-db-instance` command with the following parameters:

- `--db-instance-identifier`

- `--cloudwatch-logs-export-configuration`

Note

A change to the `--cloudwatch-logs-export-configuration` option is always applied to the DB instance immediately. Therefore, the `--apply-immediately` and `--no-apply-immediately` options have no effect.

You can also publish PostgreSQL logs by calling the following CLI commands:

- `create-db-instance`
- `restore-db-instance-from-db-snapshot`
- `restore-db-instance-to-point-in-time`

Run one of these CLI commands with the following options:

- `--db-instance-identifier`
- `--enable-cloudwatch-logs-exports`
- `--db-instance-class`
- `--engine`

Other options might be required depending on the CLI command you run.

Example Modify an instance to publish logs to CloudWatch Logs

The following example modifies an existing PostgreSQL DB instance to publish log files to CloudWatch Logs. The `--cloudwatch-logs-export-configuration` value is a JSON object. The key for this object is `EnableLogTypes`, and its value is an array of strings with any combination of `postgresql` and `upgrade`.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--cloudwatch-logs-export-configuration '{"EnableLogTypes":["postgresql", "upgrade"]}'
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--cloudwatch-logs-export-configuration '{"EnableLogTypes":["postgresql", "upgrade"]}'
```

Example Create an instance to publish logs to CloudWatch Logs

The following example creates a PostgreSQL DB instance and publishes log files to CloudWatch Logs. The `--enable-cloudwatch-logs-exports` value is a JSON array of strings. The strings can be any combination of `postgresql` and `upgrade`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--db-instance-identifier mydbinstance \
--enable-cloudwatch-logs-exports '[ "postgresql", "upgrade" ]' \
--db-instance-class db.m4.large \
```

```
--engine postgres
```

For Windows:

```
aws rds create-db-instance ^
--db-instance-identifier mydbinstance ^
--enable-cloudwatch-logs-exports '[["postgresql","upgrade"]]' ^
--db-instance-class db.m4.large ^
--engine postgres
```

RDS API

You can publish PostgreSQL logs with the RDS API. You can call the [ModifyDBInstance](#) action with the following parameters:

- [DBInstanceIdentifier](#)
- [CloudwatchLogsExportConfiguration](#)

Note

A change to the [CloudwatchLogsExportConfiguration](#) parameter is always applied to the DB instance immediately. Therefore, the [ApplyImmediately](#) parameter has no effect.

You can also publish PostgreSQL logs by calling the following RDS API operations:

- [CreateDBInstance](#)
- [RestoreDBInstanceFromDBSnapshot](#)
- [RestoreDBInstanceToPointInTime](#)

Run one of these RDS API operations with the following parameters:

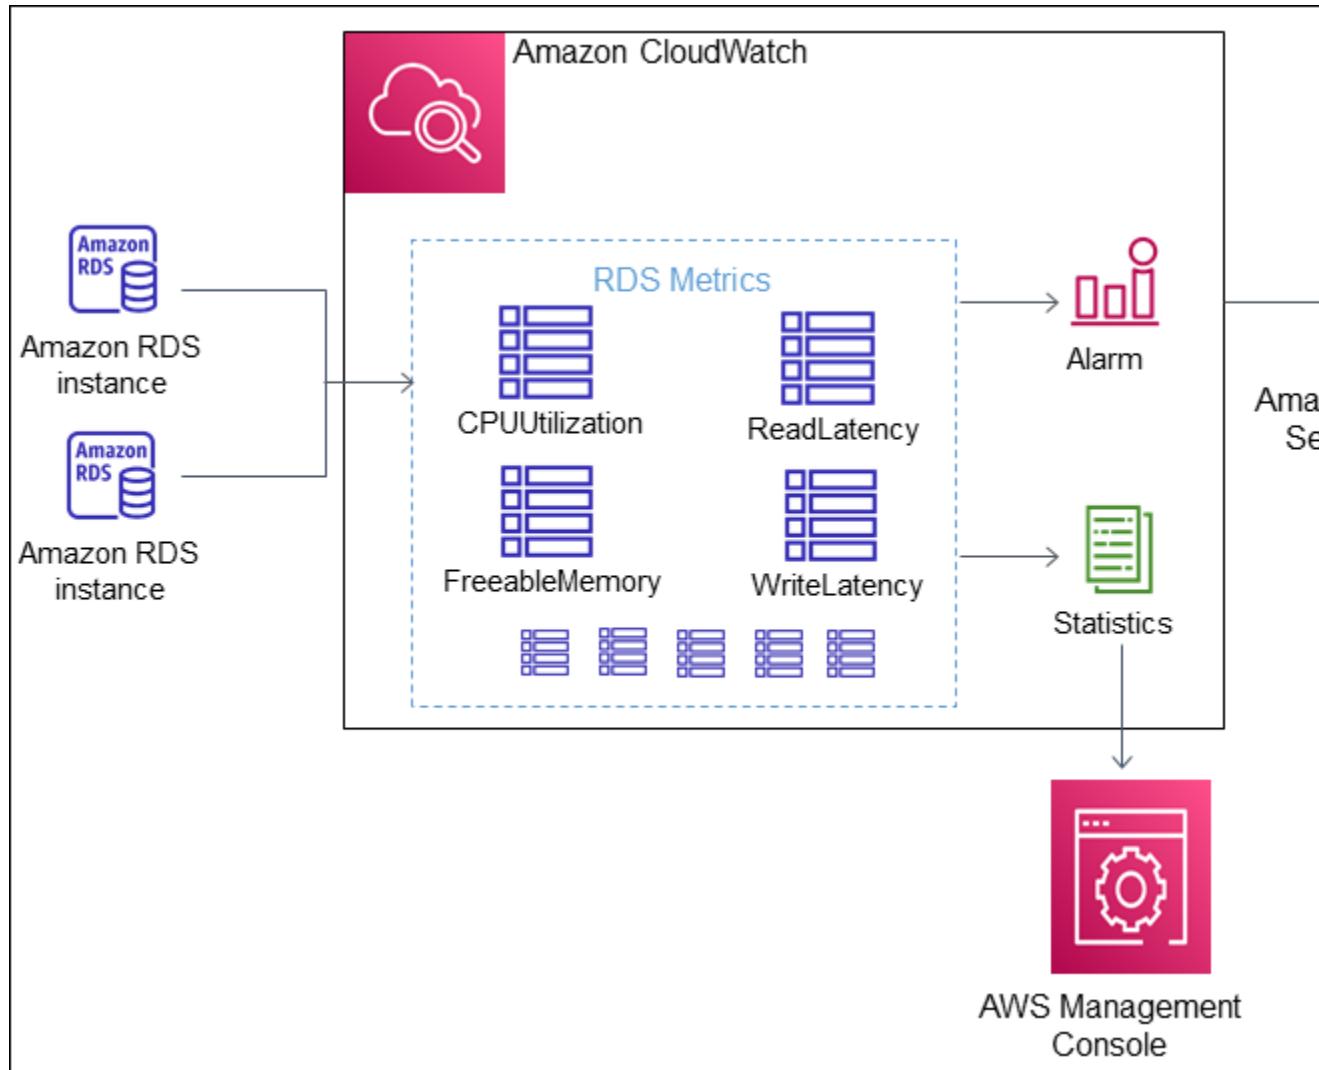

- [DBInstanceIdentifier](#)
- [EnableCloudwatchLogsExports](#)
- [Engine](#)
- [DBInstanceClass](#)

Other parameters might be required depending on the operation that you run.

Monitoring Amazon RDS metrics with Amazon CloudWatch

Amazon CloudWatch is a metrics repository. The repository collects and processes raw data from Amazon RDS into readable, near real-time metrics.

By default, Amazon RDS automatically sends metric data to CloudWatch in 1-minute periods. Data points with a period of 60 seconds (1 minute) are available for 15 days. This means that you can access historical information and see how your web application or service is performing.

For more information about CloudWatch, see [What is Amazon CloudWatch?](#) in the *Amazon CloudWatch User Guide*. For more information about CloudWatch metrics retention, see [Metrics retention](#).

Note

If you are using Amazon RDS Performance Insights, additional metrics are available. For more information, see [Performance Insights metrics published to Amazon CloudWatch \(p. 467\)](#).

Amazon RDS metrics

The AWS/RDS namespace includes the following metrics.

Note

The Amazon RDS console might display metrics in units that are different from the units sent to Amazon CloudWatch. For example, the Amazon RDS console might display a metric in megabytes (MB), while the metric is sent to Amazon CloudWatch in bytes.

Metric	Console name	Description	Units
BinLogDiskUsage	Binary Log Disk Usage (MB)	The amount of disk space occupied by binary logs on the primary. Applies to MySQL read replicas.	Bytes
BurstBalance	Burst Balance (Percent)	The percent of General Purpose SSD (gp2) burst-bucket I/O credits available.	Percent
CPUUtilization	CPU Utilization (Percent)	The percentage of CPU utilization.	Percent
CPUCreditUsage	CPU Credit Usage (Count)	(T2 instances) The number of CPU credits spent by the instance for CPU utilization. One CPU credit equals one vCPU running at 100 percent utilization for one minute or an equivalent combination of vCPUs, utilization, and time. For example, you might have one vCPU running at 50 percent utilization for two minutes or two vCPUs running at 25 percent utilization for two minutes. CPU credit metrics are available at a five-minute frequency only. If you specify a period greater than five minutes, use the <code>Sum</code> statistic instead of the <code>Average</code> statistic.	Credits (vCPU-minutes)
CPUCreditBalance	CPU Credit Balance (Count)	(T2 instances) The number of earned CPU credits that an instance has accrued since it was launched or started. For T2 Standard, the CPUCreditBalance also includes the number of launch credits that have been accrued. Credits are accrued in the credit balance after they are earned, and removed from the credit balance when they are spent. The credit balance has a maximum limit, determined by the instance size. After the limit is reached, any new credits that are earned are discarded. For T2 Standard, launch credits don't count towards the limit. The credits in the CPUCreditBalance are available for the instance to spend to burst beyond its baseline CPU utilization.	Credits (vCPU-minutes)

Metric	Console name	Description	Units
		<p>When an instance is running, credits in the <code>CPUCreditBalance</code> don't expire. When the instance stops, the <code>CPUCreditBalance</code> does not persist, and all accrued credits are lost.</p> <p>CPU credit metrics are available at a five-minute frequency only.</p>	
DatabaseConnections	DB Connections (Count)	<p>The number of database connections in use.</p> <p>The metric value might not include broken database connections that haven't been cleaned up by your database yet. So, the number of database connections recorded by your database might be higher than the metric value.</p>	Count
DiskQueueDepth	Queue Depth (Count)	The number of outstanding I/Os (read/write requests) waiting to access the disk.	Count
EBSByteBalance%	EBS Byte Balance (percent)	<p>The percentage of throughput credits remaining in the burst bucket of your RDS database. This metric is available for basic monitoring only.</p> <p>To find the instance sizes that support this metric, see the instance sizes with an asterisk (*) in the EBS optimized by default table in <i>Amazon EC2 User Guide for Linux Instances</i>. The Sum statistic is not applicable to this metric.</p>	Percent
EBSIOBalance%	EBS IO Balance (percent)	<p>The percentage of I/O credits remaining in the burst bucket of your RDS database. This metric is available for basic monitoring only.</p> <p>To find the instance sizes that support this metric, see the instance sizes with an asterisk (*) in the EBS optimized by default table in <i>Amazon EC2 User Guide for Linux Instances</i>. The Sum statistic is not applicable to this metric.</p> <p>This metric is different from <code>BurstBalance</code>. To learn how to use this metric, see Improving application performance and reducing costs with Amazon EBS-Optimized Instance burst capability.</p>	Percent
FailedSQLServerJobs	Failed SQL Server Agent Jobs Count (Count/Minute)	The number of failed Microsoft SQL Server Agent jobs during the last minute.	Count/Minute

Metric	Console name	Description	Units
FreeableMemory	Freeable Memory (MB)	The amount of available random access memory. For MariaDB, MySQL, Oracle, and PostgreSQL DB instances, this metric reports the value of the <code>MemAvailable</code> field of <code>/proc/meminfo</code> .	Bytes
FreeStorageSpace	Free Storage Space (MB/Second)	The amount of available storage space.	Bytes
MaximumUsedTransactions	Maximum Used Transaction IDs (Count)	The maximum transaction IDs that have been used. Applies to PostgreSQL.	Count
NetworkReceiveThroughput	Network Receive Throughput (MB/Second)	The incoming (receive) network traffic on the DB instance, including both customer database traffic and Amazon RDS traffic used for monitoring and replication.	Bytes/Second
NetworkTransmitThroughput	Network Transmit Throughput (MB/Second)	The outgoing (transmit) network traffic on the DB instance, including both customer database traffic and Amazon RDS traffic used for monitoring and replication.	Bytes/Second
OldestReplicationSlotLag	Oldest Replication Slot Lag (MB)	The lagging size of the replica lagging the most in terms of write-ahead log (WAL) data received. Applies to PostgreSQL.	Bytes
ReadIOPS	Read IOPS (Count/Second)	The average number of disk read I/O operations per second.	Count/Second
ReadLatency	Read Latency (Milliseconds)	The average amount of time taken per disk I/O operation.	Seconds
ReadThroughput	Read Throughput (MB/Second)	The average number of bytes read from disk per second.	Bytes/Second
ReplicaLag	Replica Lag (Milliseconds)	The amount of time a read replica DB instance lags behind the source DB instance. Applies to MySQL, MariaDB, Oracle, PostgreSQL, and SQL Server read replicas.	Seconds
ReplicationSlotDiskUsage	Replica Slot Disk Usage (MB)	The disk space used by replication slot files. Applies to PostgreSQL.	Bytes
SwapUsage	Swap Usage (MB)	The amount of swap space used on the DB instance. This metric is not available for SQL Server.	Bytes
TransactionLogsDiskUsage	Transaction Logs Disk Usage (MB)	The disk space used by transaction logs. Applies to PostgreSQL.	Bytes
TransactionLogsGeneration	TransactionLogs Generation (MB/Second)	The size of transaction logs generated per second. Applies to PostgreSQL.	Bytes/Second

Metric	Console name	Description	Units
WriteIOPS	Write IOPS (Count/Second)	The average number of disk write I/O operations per second.	Count/Second
WriteLatency	Write Latency (Milliseconds)	The average amount of time taken per disk I/O operation.	Seconds
WriteThroughput	Write Throughput (MB/Second)	The average number of bytes written to disk per second.	Bytes/Second

Amazon RDS dimensions

You can filter Amazon RDS metrics data by using any dimension in the following table.

Dimension	Filters the requested data for ...
DBInstanceIdentifier	A specific DB instance.
DatabaseClass	All instances in a database class. For example, you can aggregate metrics for all instances that belong to the database class db.r5.large.
EngineName	The identified engine name only. For example, you can aggregate metrics for all instances that have the engine name mysql.
SourceRegion	The specified Region only. For example, you can aggregate metrics for all DB instances in the us-east-1 Region.

Viewing Amazon RDS metrics and dimensions

When you use Amazon RDS resources, Amazon RDS sends metrics and dimensions to Amazon CloudWatch every minute. You can use the following procedures to view the metrics for Amazon RDS.

To view metrics using the Amazon CloudWatch console

Metrics are grouped first by the service namespace, and then by the various dimension combinations within each namespace.

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. If necessary, change the AWS Region. From the navigation bar, choose the AWS Region where your AWS resources are. For more information, see [Regions and endpoints](#).
3. In the navigation pane, choose **Metrics**. Choose the **RDS** metric namespace.

The screenshot shows the RDS metrics dashboard for the N. Virginia region. At the top, there are tabs for 'All metrics' (selected), 'Graphed metrics', 'Graph options', and 'Source'. Below the tabs, the region is set to 'N. Virginia' and the search bar contains 'Search for any metric, dimension or resource'. The main content area displays three sections: 'DBClusterIdentifier, Role' (188 Metrics), 'Per-Database Metrics' (379 Metrics), and 'Across All Databases' (61 Metrics). Each section has a link to a detailed view.

4. Choose a metric dimension, for example **By Database Class**.
5. To sort the metrics, use the column heading. To graph a metric, select the check box next to the metric. To filter by resource, choose the resource ID, and then choose **Add to search**. To filter by metric, choose the metric name, and then choose **Add to search**.

The screenshot shows the 'By Database Class' search results for the 'db.r5.large' metric. The results table has columns for 'Metric Name' and 'Value'. A context menu is open over the first row, showing options: 'Add to search', 'Search for this only', 'Remove from graph', 'Graph this metric only', 'Graph all search results', and 'What is this?'. The 'db.r5.large' checkbox is checked in the table.

To view metrics using the AWS CLI

- At a command prompt, use the following command.

```
aws cloudwatch list-metrics --namespace AWS/RDS
```

Creating CloudWatch alarms to monitor Amazon RDS

You can create a CloudWatch alarm that sends an Amazon SNS message when the alarm changes state. An alarm watches a single metric over a time period that you specify. The alarm can also perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon SNS topic or Amazon EC2 Auto Scaling policy.

Alarms invoke actions for sustained state changes only. CloudWatch alarms don't invoke actions simply because they are in a particular state. The state must have changed and have been maintained for a specified number of time periods. The following procedures show how to create alarms for Amazon RDS.

To set alarms using the CloudWatch console

- Sign in to the AWS Management Console and open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
- Choose **Alarms** and then choose **Create Alarm**. Doing this launches the Create Alarm Wizard.
- Choose **RDS Metrics** and scroll through the Amazon RDS metrics to find the metric that you want to place an alarm on. To display just Amazon RDS metrics, search for the identifier of your resource. Choose the metric to create an alarm on and then choose **Next**.
- Enter **Name**, **Description**, and **Whenever** values for the metric.
- If you want CloudWatch to send you an email when the alarm state is reached, for **Whenever this alarm**, choose **State is ALARM**. For **Send notification to**, choose an existing SNS topic. If you choose **Create topic**, you can set the name and email addresses for a new email subscription list. This list is saved and appears in the field for future alarms.

Note

If you use **Create topic** to create a new Amazon SNS topic, the email addresses must be verified before they receive notifications. Emails are only sent when the alarm enters an alarm state. If this alarm state change happens before the email addresses are verified, the addresses don't receive a notification.

- Preview the alarm that you're about to create in the **Alarm Preview** area, and then choose **Create Alarm**.

To set an alarm using the AWS CLI

- Call [put-metric-alarm](#). For more information, see [AWS CLI Command Reference](#).

To set an alarm using the CloudWatch API

- Call [PutMetricAlarm](#). For more information, see [Amazon CloudWatch API Reference](#)

Publishing database engine logs to Amazon CloudWatch Logs

You can configure your Amazon RDS database engine to publish log data to a log group in Amazon CloudWatch Logs. With CloudWatch Logs, you can perform real-time analysis of the log data, and use CloudWatch to create alarms and view metrics. You can use CloudWatch Logs to store your log records in highly durable storage, which you can manage with the CloudWatch Logs Agent. For example, you can determine when to rotate log records from a host to the log service, so you can access the raw logs when you need to.

For engine-specific information, see the following topics:

- the section called “[Publishing MariaDB logs to Amazon CloudWatch Logs](#)” (p. 509)
- the section called “[Publishing MySQL logs to Amazon CloudWatch Logs](#)” (p. 521)
- the section called “[Publishing Oracle logs to Amazon CloudWatch Logs](#)” (p. 529)
- the section called “[Publishing PostgreSQL logs to Amazon CloudWatch Logs](#)” (p. 537)
- the section called “[Publishing SQL Server logs to Amazon CloudWatch Logs](#)” (p. 516)

Note

Before you enable log data publishing, make sure that you have a service-linked role in AWS Identity and Access Management (IAM). For more information about service-linked roles, see [Using service-linked roles for Amazon RDS](#) (p. 1714).

Configuring CloudWatch log integration

To publish your database log files to CloudWatch Logs, choose which logs to publish. Make this choice in the **Advanced Settings** section when you create a new DB instance. You can also modify an existing DB instance to begin publishing.

The screenshot shows the 'Log exports' configuration screen. At the top, it says 'Select the log types to publish to Amazon CloudWatch Logs'. Below this is a list of four checked checkboxes: 'Audit log', 'Error log', 'General log', and 'Slow query log'. Underneath the checkboxes is a section titled 'IAM role' with the sub-instruction 'The following service-linked role is used for publishing logs to CloudWatch Logs.' A button labeled 'RDS Service Linked Role' is shown. At the bottom of the screen, there is a note: 'Ensure that General, Slow Query, and Audit Logs are turned on. Error logs are enabled by default.'

After you have enabled publishing, Amazon RDS continuously streams all of the DB instance log records to a log group. For example, you have a log group `/aws/rds/instance/log` type for each type of log that you publish. This log group is in the same AWS Region as the database instance that generates the log.

After you have published log records, you can use CloudWatch Logs to search and filter the records. For more information about searching and filtering logs, see [Searching and filtering log data](#). For a tutorial explaining how to monitor RDS logs, see [Build proactive database monitoring for Amazon RDS with Amazon CloudWatch Logs, AWS Lambda, and Amazon SNS](#).

Viewing DB instance metrics

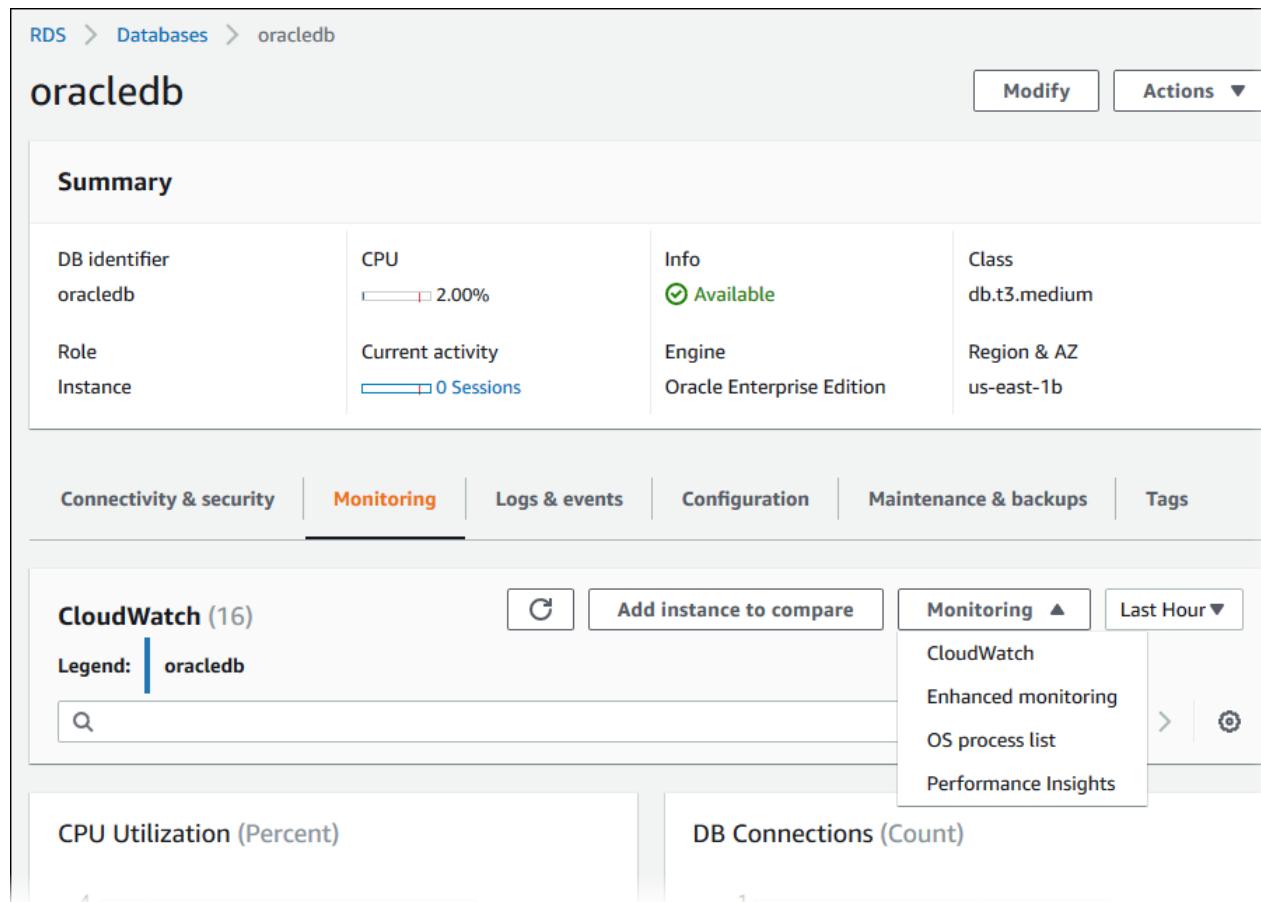

Amazon RDS provides metrics so that you can monitor the health of your DB instances. You can monitor both DB instance metrics and operating system (OS) metrics.

Following, you can find details about how to view metrics for your DB instance using the RDS console and CloudWatch. For information on monitoring metrics for your DB instance's operating system in real time using CloudWatch Logs, see [Using Enhanced Monitoring \(p. 471\)](#).

Viewing metrics by using the console

To view DB and OS metrics for a DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases**.
3. Choose the name of the DB instance that you need information about to show its details.
4. Choose the **Monitoring** tab.
5. For **Monitoring**, choose the option for how you want to view your metrics from these:
 - **CloudWatch** – Shows a summary of DB instance metrics available from Amazon CloudWatch. Each metric includes a graph showing the metric monitored over a specific time span.
 - **Enhanced monitoring** – Shows a summary of OS metrics available for a DB instance with Enhanced Monitoring enabled. Each metric includes a graph showing the metric monitored over a specific time span.
 - **OS Process list** – Shows details for each process running in the selected instance.
 - **Performance Insights** – Opens the Amazon RDS Performance Insights console for your DB instance.

Tip

To choose the time range of the metrics represented by the graphs, you can use the time range list.

To bring up a more detailed view, you can choose any graph. You can also apply metric-specific filters to the data.

Viewing DB instance metrics with the CLI or API

Amazon RDS integrates with CloudWatch metrics to provide a variety of DB instance metrics. You can view CloudWatch metrics using the RDS console, AWS CLI, or API.

For a complete list of Amazon RDS metrics, go to [Amazon RDS dimensions and metrics](#) in the *Amazon CloudWatch User Guide*.

Viewing DB metrics by using the CloudWatch CLI

Note

The following CLI example requires the CloudWatch command line tools. For more information on CloudWatch and to download the developer tools, see [Amazon CloudWatch](#) on the AWS website. The `StartTime` and `EndTime` values supplied in this example are for illustration only. Substitute appropriate start and end time values for your DB instance.

To view usage and performance statistics for a DB instance

- Use the CloudWatch command `mon-get-stats` with the following parameters.

```
PROMPT>mon-get-stats FreeStorageSpace --dimensions="DBInstanceIdentifier=mydbinstance"
--statistics= Average
--namespace="AWS/RDS" --start-time 2009-10-16T00:00:00 --end-time 2009-10-16T00:02:00
```

[Viewing DB metrics by using the CloudWatch API](#)

The `StartTime` and `EndTime` values supplied in this example are for illustration only. Substitute appropriate start and end time values for your DB instance.

To view usage and performance statistics for a DB instance

- Call the CloudWatch API `GetMetricStatistics` with the following parameters:
 - `Statistics.member.1 = Average`
 - `Namespace = AWS/RDS`
 - `StartTime = 2009-10-16T00:00:00`
 - `EndTime = 2009-10-16T00:02:00`
 - `Period = 60`
 - `MeasureName = FreeStorageSpace`

Getting CloudWatch Events and Amazon EventBridge events for Amazon RDS

Using Amazon CloudWatch Events and Amazon EventBridge, you can automate AWS services and respond to system events such as application availability issues or resource changes.

Topics

- [Overview of events for Amazon RDS \(p. 551\)](#)
- [Creating rules to send Amazon RDS events to CloudWatch Events \(p. 553\)](#)
- [Tutorial: log the state of an Amazon RDS instance using EventBridge \(p. 554\)](#)

Overview of events for Amazon RDS

An *event* indicates a change in an environment. This can be an AWS environment, an SaaS partner service or application, or one of your own custom applications or services. For example, Amazon RDS generates an event when the state of an instance changes from pending to running. Amazon RDS deliver events to CloudWatch Events and EventBridge in near real time.

Note

Amazon RDS emits events on a best effort basis. We recommend that you avoid writing programs that depends on the order or existence of notification events, as they might be out of sequence or missing.

You can write simple rules to indicate which events interest you and what automated actions to take when an event matches a rule. You can set a variety of targets, such as an AWS Lambda function or an Amazon SNS topic, which receive events in JSON format. For example, you can configure Amazon RDS to send events to CloudWatch Events or Amazon EventBridge whenever a DB instance is created or deleted. For more information, see the [Amazon CloudWatch Events User Guide](#) and the [Amazon EventBridge User Guide](#).

- [DB snapshot events \(p. 553\)](#)

DB instance events

The following is an example of a DB instance event.

```
{  
  "version": "0",  
  "id": "68f6e973-1a0c-d37b-f2f2-94a7f62ffd4e",  
  "detail-type": "RDS DB Instance Event",  
  "source": "aws.rds",  
  "account": "123456789012",  
  "time": "2018-09-27T22:36:43Z",  
  "region": "us-east-1",  
  "resources": [  
    "arn:aws:rds:us-east-1:123456789012:db:my-db-instance"  
  ],  
  "detail": {
```

```
    "EventCategories": [
        "failover"
    ],
    "SourceType": "DB_INSTANCE",
    "SourceArn": "arn:aws:rds:us-east-1:123456789012:db:my-db-instance",
    "Date": "2018-09-27T22:36:43.292Z",
    "Message": "A Multi-AZ failover has completed.",
    "SourceIdentifier": "rds:my-db-instance",
    "EventID": "RDS-EVENT-0049"
}
}
```

DB parameter group events

The following is an example of a DB parameter group event.

```
{
    "version": "0",
    "id": "844e2571-85d4-695f-b930-0153b71dc42",
    "detail-type": "RDS DB Parameter Group Event",
    "source": "aws.rds",
    "account": "123456789012",
    "time": "2018-10-06T12:26:13Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:rds:us-east-1:123456789012:pg:my-db-param-group"
    ],
    "detail": {
        "EventCategories": [
            "configuration change"
        ],
        "SourceType": "DB_PARAM",
        "SourceArn": "arn:aws:rds:us-east-1:123456789012:pg:my-db-param-group",
        "Date": "2018-10-06T12:26:13.882Z",
        "Message": "Updated parameter time_zone to UTC with apply method immediate",
        "SourceIdentifier": "rds:my-db-param-group",
        "EventID": "RDS-EVENT-0037"
    }
}
```

DB security group events

The following is an example of a DB security group event.

```
{
    "version": "0",
    "id": "844e2571-85d4-695f-b930-0153b71dc42",
    "detail-type": "RDS DB Security Group Event",
    "source": "aws.rds",
    "account": "123456789012",
    "time": "2018-10-06T12:26:13Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:rds:us-east-1:123456789012:secgrp:my-security-group"
    ],
    "detail": {
        "EventCategories": [
            "configuration change"
        ],
        "SourceType": "SECURITY_GROUP",
        "SourceArn": "arn:aws:rds:us-east-1:123456789012:secgrp:my-security-group",
        "Date": "2018-10-06T12:26:13.882Z",
        "Message": "Updated security group rule for my-security-group with port 3306"
    }
}
```

```
        "Message": "Applied change to security group",
        "SourceIdentifier": "rds:my-security-group",
        "EventID": "RDS-EVENT-0038"
    }
}
```

DB snapshot events

The following is an example of a DB snapshot event.

```
{
    "version": "0",
    "id": "844e2571-85d4-695f-b930-0153b71dc42",
    "detail-type": "RDS DB Snapshot Event",
    "source": "aws.rds",
    "account": "123456789012",
    "time": "2018-10-06T12:26:13Z",
    "region": "us-east-1",
    "resources": [
        "arn:aws:rds:us-east-1:123456789012:snapshot:rds:my-db-snapshot"
    ],
    "detail": {
        "EventCategories": [
            "deletion"
        ],
        "SourceType": "SNAPSHOT",
        "SourceArn": "arn:aws:rds:us-east-1:123456789012:snapshot:rds:my-db-snapshot",
        "Date": "2018-10-06T12:26:13.882Z",
        "Message": "Deleted manual snapshot",
        "SourceIdentifier": "rds:my-db-snapshot",
        "EventID": "RDS-EVENT-0041"
    }
}
```

Creating rules to send Amazon RDS events to CloudWatch Events

You can create CloudWatch Events rules to send Amazon RDS events to CloudWatch Events.

Use the following steps to create a CloudWatch Events rule that triggers on an event emitted by an AWS service.

To create a rule that triggers on an event:

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. Under **Events** in the navigation pane, choose **Rules**.
3. Choose **Create rule**.
4. For **Event Source**, do the following:
 - a. Choose **Event Pattern**.
 - b. For **Service Name**, choose **Relational Database Service (RDS)**.
 - c. For **Event Type**, choose the type of Amazon RDS resource that triggers the event. For example, if a DB instance triggers the event, choose **RDS DB Instance Event**.
5. For **Targets**, choose **Add Target** and choose the AWS service that is to act when an event of the selected type is detected.
6. In the other fields in this section, enter information specific to this target type, if any is needed.

7. For many target types, CloudWatch Events needs permissions to send events to the target. In these cases, CloudWatch Events can create the IAM role needed for your event to run:
 - To create an IAM role automatically, choose **Create a new role for this specific resource**.
 - To use an IAM role that you created before, choose **Use existing role**.
8. Optionally, repeat steps 5-7 to add another target for this rule.
9. Choose **Configure details**. For **Rule definition**, type a name and description for the rule.

The rule name must be unique within this Region.
10. Choose **Create rule**.

For more information, see [Creating a CloudWatch Events Rule That Triggers on an Event](#) in the *Amazon CloudWatch User Guide*.

Tutorial: log the state of an Amazon RDS instance using EventBridge

You can create an AWS Lambda function that logs the changes in state for an Amazon RDS instance. You can choose to create a rule that runs the function whenever there is a state transition or a transition to one or more states that are of interest.

In this tutorial, you log any state change of an existing RDS DB instance. The tutorial assumes that you have a small running test instance that you can shut down temporarily.

Important

Don't perform this tutorial on a running production instance.

Step 1: Create an AWS Lambda Function

Create a Lambda function to log the state change events. You specify this function when you create your rule.

To create a Lambda function

1. Open the AWS Lambda console at <https://console.aws.amazon.com/lambda/>.
2. If you're new to Lambda, you see a welcome page. Choose **Get Started Now**. Otherwise, choose **Create function**.
3. Choose **Author from scratch**.
4. On the **Create function** page, do the following:
 - a. Enter a name and description for the Lambda function. For example, name the function **RDSInstanceStateChange**.
 - b. In **Runtime**, select **Node.js 14x**.
 - c. In **Execution role**, choose **Create a new role with basic Lambda permissions**. For **Existing role**, select your basic execution role. Otherwise, create a basic execution role.
 - d. Choose **Create function**.
5. On the **RDSInstanceStateChange** page, do the following:
 - a. In **Code source**, select **index.js**.
 - b. Right-click **index.js**, and choose **Open**.
 - c. In the **index.js** pane, delete the existing code.
 - d. Enter the following code:

```
console.log('Loading function');

exports.handler = async (event, context) => {
    console.log('Received event:', JSON.stringify(event));
};
```

- e. Choose **Deploy**.

Step 2: Create a Rule

Create a rule to run your Lambda function whenever you launch an Amazon RDS instance.

To create the EventBridge rule

1. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
2. In the navigation pane, choose **Rules**.
3. Choose **Create rule**.
4. Enter a name and description for the rule. For example, enter **RDSInstanceStateChangeRule**.
5. For **Define pattern**, do the following:
 - a. Choose **Event pattern**.
 - b. Choose **Pre-defined pattern by service**.
 - c. For **Service provider**, choose **AWS**.
 - d. For **Service Name**, choose **Relational Database Service (RDS)**.
 - e. For **Event type**, choose **RDS DB Instance Event**.
6. For **Select event bus**, choose **AWS default event bus**. When an AWS service in your account emits an event, it always goes to your account's default event bus.
7. For **Target**, choose **Lambda function**.
8. For **Function**, select the Lambda function that you created.
9. Choose **Create**.

Step 3: Test the Rule

To test your rule, shut down an RDS DB instance. After waiting a few minutes for the instance to shut down, verify that your Lambda function was invoked.

To test your rule by stopping a DB instance

1. Open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Stop an RDS DB instance.
3. Open the Amazon EventBridge console at <https://console.aws.amazon.com/events/>.
4. In the navigation pane, choose **Rules**, choose the name of the rule that you created.
5. In **Rule details**, choose **Metrics for the rule**.

You are redirected to the Amazon CloudWatch console.
6. In **All metrics**, choose the name of the rule that you created.

The graph should indicate that the rule was invoked.
7. In the navigation pane, choose **Log groups**.
8. Choose the name of the log group for your Lambda function (**/aws/lambda/*function-name***).

9. Choose the name of the log stream to view the data provided by the function for the instance that you launched. You should see a received event similar to the following:

```
{  
    "version": "0",  
    "id": "12a345b6-78c9-01d2-34e5-123f4ghi5j6k",  
    "detail-type": "RDS DB Instance Event",  
    "source": "aws.rds",  
    "account": "111111111111",  
    "time": "2021-03-19T19:34:09Z",  
    "region": "us-east-1",  
    "resources": [  
        "arn:aws:rds:us-east-1:111111111111:db:testdb"  
    ],  
    "detail": {  
        "EventCategories": [  
            "notification"  
        ],  
        "SourceType": "DB_INSTANCE",  
        "SourceArn": "arn:aws:rds:us-east-1:111111111111:db:testdb",  
        "Date": "2021-03-19T19:34:09.293Z",  
        "Message": "DB instance stopped",  
        "SourceIdentifier": "testdb",  
        "EventID": "RDS-EVENT-0087"  
    }  
}
```

10. (Optional) When you're finished, you can open the Amazon RDS console and start the instance that you stopped.

Working with AWS CloudTrail and Amazon RDS

AWS CloudTrail is an AWS service that helps you audit your AWS account. CloudTrail is enabled on your AWS account when you create it.

For complete information about CloudTrail, see the [AWS CloudTrail User Guide](#).

CloudTrail integration with Amazon RDS

All Amazon RDS actions are logged by CloudTrail. CloudTrail provides a record of actions taken by a user, role, or an AWS service in Amazon RDS.

CloudTrail events

CloudTrail captures API calls for Amazon RDS as events. An *event* represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. Events include calls from the Amazon RDS console and from code calls to the Amazon RDS APIs.

Amazon RDS activity is recorded in a CloudTrail event in **Event history**. You can use the CloudTrail console to view the last 90 days of recorded API activity and events in an AWS Region. For more information, see [Viewing events with CloudTrail event history](#).

CloudTrail trails

For an ongoing record of events in your AWS account, including events for Amazon RDS, create a *trail*. A trail is a configuration that enables delivery of events to a specified Amazon S3 bucket. CloudTrail typically delivers log files within 15 minutes of account activity.

Note

If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**.

You can create two types of trails for an AWS account: a trail that applies to all regions, or a trail that applies to one region. By default, when you create a trail in the console, the trail applies to all regions.

Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see:

- Overview for creating a trail
 - CloudTrail supported services and integrations
 - Configuring Amazon SNS notifications for CloudTrail
 - Receiving CloudTrail log files from multiple Regions and Receiving CloudTrail log files from multiple accounts

Amazon RDS log file entries

CloudTrail log files contain one or more log entries. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

The following example shows a CloudTrail log entry that demonstrates the `CreateDBInstance` action.

```
{  
    "eventVersion": "1.04",  
    "userIdentity": {  
        "type": "TAMUser"  
    }  
}
```

```

}

```

As shown in the `userIdentity` element in the preceding example, every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.
- Whether the request was made by another AWS service.

For more information about the `userIdentity`, see the [CloudTrail userIdentity element](#). For more information about `CreateDBInstance` and other Amazon RDS actions, see the [Amazon RDS API Reference](#).

Working with Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts extends Amazon RDS for MySQL and PostgreSQL databases to AWS Outposts environments. AWS Outposts uses the same hardware as in public AWS Regions to bring AWS services, infrastructure, and operation models on-premises. With RDS on Outposts, you can provision managed DB instances close to the business applications that must run on-premises. For more information about AWS Outposts, see [AWS Outposts](#).

You use the same AWS Management Console, AWS CLI, and RDS API to provision and manage on-premises RDS on Outposts DB instances as you do for RDS DB instances running in the AWS Cloud. RDS on Outposts automates tasks, such as database provisioning, operating system and database patching, backup, and long-term archival in Amazon S3.

RDS on Outposts supports automated backups of DB instances. Network connectivity between your Outpost and your AWS Region is required to back up and restore DB instances. All DB snapshots and transaction logs from an Outpost are stored in your AWS Region. From your AWS Region, you can restore a DB instance from a DB snapshot to a different Outpost. For more information, see [Working with backups \(p. 328\)](#).

RDS on Outposts supports automated maintenance and upgrades of DB instances. For more information, see [Maintaining a DB instance \(p. 264\)](#).

RDS on Outposts uses encryption at rest for DB instances and DB snapshots using your AWS Key Management Service (AWS KMS) key. For more information about encryption at rest, see [Encrypting Amazon RDS resources \(p. 1630\)](#).

By default, EC2 instances in Outposts subnets can use the Amazon Route 53 DNS Service to resolve domain names to IP addresses. You might encounter longer DNS resolution times with Route 53, depending on the path latency between your Outpost and the AWS Region. In such cases, you can use the DNS servers installed locally in your on-premises environment. For more information, see [DNS](#) in the [AWS Outposts User Guide](#).

When network connectivity to the AWS Region isn't available, your DB instance continues to run locally. You can continue to access DB instances using DNS name resolution by configuring a local DNS server as a secondary server. However, you can't create new DB instances or take new actions on existing DB instances. Automatic backups don't occur when there is no connectivity. If there is a DB instance failure, the DB instance isn't automatically replaced until connectivity is restored. We recommend restoring network connectivity as soon as possible.

Topics

- [Prerequisites for Amazon RDS on AWS Outposts \(p. 561\)](#)
- [Amazon RDS on AWS Outposts support for Amazon RDS features \(p. 562\)](#)
- [Supported DB instance classes for Amazon RDS on AWS Outposts \(p. 564\)](#)
- [Customer-owned IP addresses for RDS on Outposts \(p. 565\)](#)
- [Creating DB instances for Amazon RDS on AWS Outposts \(p. 567\)](#)

Prerequisites for Amazon RDS on AWS Outposts

The following are prerequisites for using Amazon RDS on AWS Outposts:

- Install AWS Outposts in your on-premises data center. For more information about AWS Outposts, see [AWS Outposts](#).
- Make sure that you have at least one subnet available for RDS on Outposts. You can use the same subnet for other workloads.
- Make sure that you have a reliable network connection between your Outpost and an AWS Region.

Amazon RDS on AWS Outposts support for Amazon RDS features

Feature	Supported	Notes	More information
DB instance provisioning	Yes	You can only create DB instances for RDS for MySQL and RDS for PostgreSQL DB engines. The following versions are supported: <ul style="list-style-type: none"> MySQL versions 8.0.17, 8.0.19, 8.0.20, and 8.0.21 PostgreSQL versions 12.2, 12.3, and 12.4 	Creating an Amazon RDS DB instance (p. 141)
Modifying the master user password	Yes	—	Modifying an Amazon RDS DB instance (p. 250)
Renaming a DB instance	Yes	—	Modifying an Amazon RDS DB instance (p. 250)
Rebooting a DB instance	Yes	—	Rebooting a DB instance (p. 276)
Stopping a DB instance	Yes	—	Stopping an Amazon RDS DB instance temporarily (p. 246)
Starting a DB instance	Yes	—	Starting an Amazon RDS DB instance that was previously stopped (p. 249)
Multi-AZ deployments	No	—	High availability (Multi-AZ) for Amazon RDS (p. 53)
DB parameter groups	Yes	—	Working with DB parameter groups (p. 228)
Read replicas	No	—	Working with read replicas (p. 278)
Encryption at rest	Yes	RDS on Outposts doesn't support unencrypted DB instances.	Encrypting Amazon RDS resources (p. 1630)
AWS Identity and Access Management	No	—	IAM database authentication for MySQL and PostgreSQL (p. 1660)

Feature	Supported	Notes	More information
(IAM) database authentication		—	
Associating an IAM role with a DB instance	No	—	add-role-to-db-instance CLI command and AddRoleToDBInstance RDS API operation
Kerberos authentication	No	—	Kerberos authentication (p. 1629)
Tagging Amazon RDS resources	Yes	—	Tagging Amazon RDS resources (p. 299)
Option groups	Yes	—	Working with option groups (p. 212)
Modifying the maintenance window	Yes	—	Maintaining a DB instance (p. 264)
Automatic minor version upgrade	Yes	—	Automatically upgrading the minor engine version (p. 273)
Modifying the backup window	Yes	—	Working with backups (p. 328) and Modifying an Amazon RDS DB instance (p. 250)
DB instance scaling	Yes	To scale a DB instance, modify its on-premises DB instance class. Storage scaling isn't supported.	Modifying an Amazon RDS DB instance (p. 250)
Manual and automatic DB instance snapshots	Yes	Manual and automatic DB instance snapshots are stored in your AWS Region.	Creating a DB snapshot (p. 346)
Restoring from a DB snapshot	Yes	—	Restoring from a DB snapshot (p. 349)
Restoring a DB instance from Amazon S3	No	—	Restoring a backup into a MySQL DB instance (p. 871)
Exporting snapshot data to Amazon S3	Yes	—	Exporting DB snapshot data to Amazon S3 (p. 373)
Point-in-time recovery	Yes	—	Restoring a DB instance to a specified time (p. 389)
Enhanced monitoring	No	—	Using Enhanced Monitoring (p. 471)

Feature	Supported	Notes	More information
Amazon CloudWatch monitoring	Yes	You can view the same set of metrics that are available for your databases in the AWS Region.	Monitoring Amazon RDS metrics with Amazon CloudWatch (p. 540)
Publishing database engine logs to CloudWatch Logs	No	—	Publishing database logs to Amazon CloudWatch Logs (p. 506)
Event notification	Yes	—	Using Amazon RDS event notification (p. 487)
Amazon RDS Performance Insights	No	—	Using Performance Insights on Amazon RDS (p. 412)
Viewing or downloading database logs	No	RDS on Outposts doesn't support viewing database logs using the console or describing database logs using the CLI or RDS API. RDS on Outposts doesn't support downloading database logs using the console or downloading database logs using the CLI or RDS API.	Accessing Amazon RDS database log files (p. 504)
Amazon RDS Proxy	No	—	Managing connections with Amazon RDS Proxy (p. 167)
Stored procedures for Amazon RDS for MySQL	Yes	—	MySQL on Amazon RDS SQL reference (p. 952)
Replication with external databases for Amazon RDS for MySQL	No	—	Replication with a MySQL or MariaDB instance running external to Amazon RDS (p. 914)

Note

RDS on Outposts doesn't support use cases that require all data to remain in your data center.
RDS on Outposts stores database backups and logs in your AWS Region.

Supported DB instance classes for Amazon RDS on AWS Outposts

Amazon RDS on AWS Outposts supports the following DB instance classes:

- General Purpose DB instance classes
 - db.m5.24xlarge

- db.m5.12xlarge
- db.m5.4xlarge
- db.m5.2xlarge
- db.m5.xlarge
- db.m5.large
- Memory Optimized DB instance classes
 - db.r5.24xlarge
 - db.r5.12xlarge
 - db.r5.4xlarge
 - db.r5.2xlarge
 - db.r5.xlarge
 - db.r5.large

Only General Purpose SSD storage is supported for RDS on Outposts DB instances. For more information about DB instance classes, see [DB instance classes \(p. 7\)](#).

Amazon RDS manages maintenance and recovery for your DB instances and requires active capacity on the Outpost to do so. We recommend that you configure N+1 EC2 instances for each DB instance class in your production environments. RDS on Outposts can use the extra capacity of these EC2 instances for maintenance and repair operations. For example, if your production environments have 3 db.m5.large and 5 db.r5.xlarge DB instance classes, then we recommend that they have at least 4 m5.large EC2 instances and 6 r5.xlarge EC2 instances. For more information, see [Resilience in AWS Outposts](#) in the [AWS Outposts User Guide](#).

Customer-owned IP addresses for RDS on Outposts

AWS Outposts uses information that you provide about your on-premises network to create an address pool, known as a *customer-owned IP address pool* (CoIP pool). *Customer-owned IP addresses* (CoIPs) provide local or external connectivity to resources in your Outpost subnets through your on-premises network. For more information about CoIPs, see [Customer-owned IP addresses](#) in the [AWS Outposts User Guide](#).

Each RDS on Outposts DB instance has a private IP address for traffic inside its virtual private cloud (VPC). This private IP address isn't publicly accessible. You can use the **Public** option to designate whether the DB instance also has a public IP address in addition to the private IP address. Using the public IP address for connections routes them through the internet and can result in high latencies in some cases.

Instead of using these private and public IP addresses, RDS on Outposts supports enabling a CoIP for DB instances through their subnets. When you enable a CoIP for an RDS on Outposts DB instance, you connect to the DB instance with the DB instance endpoint. RDS on Outposts automatically uses the CoIP for all connections from both inside and outside of the VPC.

CoIPs can provide the following benefits for RDS on Outposts DB instances:

- Lower connection latency
- Enhanced security

You can enable or disable a CoIP for an RDS on Outposts DB instance using the AWS Management Console, the AWS CLI, or the RDS API:

- With the AWS Management Console, use the **Customer-owned IP address (CoIP)** setting in **Access type** to enable a CoIP. Use one of the other settings to disable it.

▼ Additional configuration

Access type [Info](#)

Private

RDS will not assign a public IP address to the database. Amazon EC2 instances and devices inside the VPC can connect to your database. EC2 instances and devices outside your VPC can't connect unless they use AWS Site-to-Site VPN or AWS Direct Connect.

Customer-owned IP address (CoIP)

Devices on your on-premises network can connect to your database through a CoIP.

Public

Amazon EC2 instances and devices outside the VPC can connect to your database. Choose one or more VPC security groups that specify which EC2 instances and devices can connect to the database.

Database port

TCP/IP port that the database will use for application connections.

3306

- With the AWS CLI, use the `--enable-customer-owned-ip` | `--no-enable-customer-owned-ip` option.
- With the RDS API, use the `EnableCustomerOwnedIp` parameter.

You can enable or disable a CoIP when you perform any of the following actions:

- Create a DB instance

For more information, see [Creating DB instances for Amazon RDS on AWS Outposts \(p. 567\)](#).

- Modify a DB instance

For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

- Restore a DB instance from a snapshot

For more information, see [Restoring from a DB snapshot \(p. 349\)](#).

- Restore a DB instance to a specified time

For more information, see [Restoring a DB instance to a specified time \(p. 389\)](#).

Note

If you enable a CoIP for a DB instance, but Amazon RDS is unable to allocate a CoIP for the DB instance, the DB instance status is changed to **incompatible-network**. For more information about the DB instance status, see [DB instance status \(p. 404\)](#).

The following limitations apply to CoIP support for RDS on Outposts DB instances:

- When a CoIP is enabled for a DB instance, make sure that public accessibility is disabled for the DB instance.
- You can't assign a CoIP from a CoIP pool to a DB instance. When you enable a CoIP for a DB instance, Amazon RDS automatically assigns a CoIP from a CoIP pool to the DB instance.

- You must use the AWS account that owns the Outpost resources (owner) or share the following resources with other AWS accounts (consumers) in the same organization.
 - The Outpost
 - The local gateway (LGW) route table for the DB instance's VPC
 - The CoIP pool or pools for the LGW route table

For more information, see [Working with shared AWS Outposts resources](#) in the *AWS Outposts User Guide*.

Creating DB instances for Amazon RDS on AWS Outposts

Creating an Amazon RDS on AWS Outposts DB instance is similar to creating an Amazon RDS DB instance in the AWS Cloud. However, you must specify a DB subnet group that is associated with your Outpost.

An Amazon VPC can span all of the Availability Zones in an AWS Region. You can extend any VPC in the AWS Region to your Outpost by adding an Outpost subnet. To add an Outpost subnet to a VPC, specify the Amazon Resource Name (ARN) of the Outpost when you create the subnet.

Before you create an RDS on Outposts DB instance, you can create a DB subnet group that includes one subnet that is associated with your Outpost. When you create an RDS on Outposts DB instance, specify this DB subnet group. You can also choose to create a new DB subnet group when you create your DB instance.

For information about configuring AWS Outposts, see the [AWS Outposts User Guide](#).

Console

To create an RDS on Outposts DB instance using the console

1. Create a DB subnet group with one subnet that is associated with your Outpost.

To create a new DB subnet group for the Outpost when you create your DB instance, skip this step.

Note

To create a DB subnet group for the AWS Cloud, you specify at least two subnets. However, for an Outpost DB subnet group, you can specify only one subnet.

- a. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
- b. In the upper-right corner of the Amazon RDS console, choose the AWS Region where you want to create the DB subnet group.
- c. Choose **Subnet groups**, and then choose **Create DB Subnet Group**.

The **Create DB subnet group** page appears.

The screenshot shows the 'Create DB Subnet Group' wizard. At the top, a breadcrumb navigation shows 'RDS > Subnet groups > Create DB subnet group'. The main title is 'Create DB Subnet Group'. A descriptive text below the title says: 'To create a new subnet group, give it a name and a description, and choose an existing VPC. You will then be able to add subnets related to that VPC.' The first section, 'Subnet group details', contains fields for 'Name' (with a note: 'You won't be able to modify the name after your subnet group has been created.') and 'Description'. The 'VPC' section allows selecting a VPC identifier from a dropdown menu labeled 'Choose a VPC'. The second section, 'Add subnets', contains fields for 'Availability Zones' (with a note: 'Choose the Availability Zones that include the subnets you want to add.') and 'Subnets' (with a note: 'Choose the subnets that you want to add. The list includes the subnets in the selected Availability Zones.').

- d. Set the following values for your new DB subnet group:
 - **Name** – The name of the DB subnet group
 - **Description** – A description for the DB subnet group
 - **VPC** – The VPC for which you're creating the DB subnet group
 - e. For **Availability Zones**, choose the Availability Zone for your Outpost.
 - f. For **Subnets**, choose the subnet for use by RDS on Outposts.

Your DB subnet group must have only one subnet.
 - g. Choose **Create** to create the DB subnet group.
2. Create the DB instance, and choose the Outpost for your DB instance.
 - a. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
 - b. In the upper-right corner of the Amazon RDS console, choose the AWS Region where you want to create the DB instance.

- c. In the navigation pane, choose **Databases**.
- d. Choose **Create database**.

The AWS Management Console detects available Outposts that you have configured and presents the **On-premises** option in the **Database location** section.

Create database

Database location
Choose a location to meet your use case. [Info](#)

Database location options

Amazon Cloud
Use Amazon's cloud to store and provision a database instance with RDS.

On-premises
Create a DB instance on-premises using an AWS Outpost or VMware datacenter.

Choose an on-premises creation method [Info](#)

On-premises database options

RDS on Outposts
Use an AWS outpost to create a DB instance on-premises.

RDS on VMware
Use a custom AZ to create a DB instance with an on-premises VMware datacenter.

Outposts Connectivity

Virtual private cloud (VPC) [Info](#)
VPC that defines the virtual networking environment for this DB instance.

vpc-0069a9625caeda794

Only VPCs with an Outpost subnet are listed.

VPC security group

Choose VPC security groups

Subnet group [Info](#)
DB subnet group that defines which subnets and IP ranges the DB instance can use in the VPC you selected.

Choose existing
Choose existing subnet group

Create new
Create new subnet group

Add subnets to DB subnet group.

subnet-0dbe9e254c8463e33 (Outpost: op-09d7a5baee9402a08)

Note

If you haven't configured any Outposts, either the **Database location** section doesn't appear or the **RDS on Outposts** option isn't available in the **Choose an on-premises creation method** section.

- e. Choose the following settings:
 - **Database location – On-premises**
 - **On-premises creation method – RDS on Outposts**
 - **Outpost** – The Outpost that uses the virtual private cloud (VPC) that has the DB subnet group for your DB instance. Your VPC here must be based on the Amazon VPC service.
 - **Virtual Private Cloud (VPC)** – The VPC that contains the DB subnet group for your DB instance.
 - **VPC security group** – The Amazon VPC security group for your DB instance.

- **Subnet group** – The DB subnet group for your DB instance.

You can choose an existing DB subnet group that is associated with the Outpost. If you didn't create a DB subnet group, you can create a new DB subnet group for the Outpost. Only one subnet is allowed in this DB subnet group.

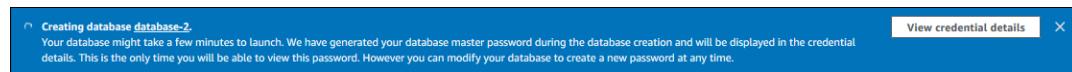

- For the remaining sections, specify your DB instance settings.

For information about each setting when creating a DB instance, see [Settings for DB instances \(p. 145\)](#).

- Choose **Create database**.

If you chose to use an automatically generated password, the **View credential details** button appears on the **Databases** page.

To view the master user name and password for the DB instance, choose **View credential details**.

To connect to the DB instance as the master user, use the user name and password that appear.

Important

You can't view the master user password again. If you don't record it, you might have to change it. To change the master user password after the DB instance is available, modify the DB instance. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

- For **Databases**, choose the name of the new DB instance.

On the RDS console, the details for the new DB instance appear. The DB instance has a status of **Creating** until the DB instance is created and ready for use. When the state changes to **Available**, you can connect to the DB instance. Depending on the DB instance class and storage allocated, it can take several minutes for the new DB instance to be available.

The screenshot shows the RDS Databases page. The top navigation bar shows "RDS > Databases > database-1". On the right, there are "Modify" and "Actions" buttons. The main area shows a table with the following data:

Summary			
DB identifier database-1	CPU -	Info Creating	Class db.m5.xlarge
Role Instance	Current activity 0 Sessions	Engine MySQL Community	Region & AZ -

Below the table, there are tabs for "Connectivity & security" (which is highlighted in red), "Monitoring", "Logs & events", "Configuration", and "Maintenance & backups".

After the DB instance is available, you can manage it the same way that you manage RDS DB instances in the cloud.

AWS CLI

To create a new DB instance in an Outpost with the AWS CLI, first create a DB subnet group for use by RDS on Outposts by calling the [create-db-subnet-group](#) command. For `--subnet-ids`, specify the subnet group in the Outpost for use by RDS on Outposts.

For Linux, macOS, or Unix:

```
aws rds create-db-subnet-group \
--db-subnet-group-name myoutpostdbsubnetgr \
--db-subnet-group-description "DB subnet group for RDS on Outposts" \
--subnet-ids subnet-abc123
```

For Windows:

```
aws rds create-db-subnet-group ^
--db-subnet-group-name myoutpostdbsubnetgr ^
--db-subnet-group-description "DB subnet group for RDS on Outposts" ^
--subnet-ids subnet-abc123
```

Next, call the [create-db-instance](#) command with the parameters below. Specify an Availability Zone for the Outpost, an Amazon VPC security group associated with the Outpost, and the DB subnet group you created for the Outpost. You can include the following options:

- `--db-instance-identifier`
- `--db-instance-class`
- `--engine`
- `--availability-zone`
- `--vpc-security-group-ids`
- `--db-subnet-group-name`
- `--allocated-storage`
- `--master-user-name`
- `--master-user-password`
- `--backup-retention-period`
- `--storage-encrypted`
- `--kms-key-id`

Example

The following example creates a MySQL DB instance named `myoutpostdbinstance`.

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--db-instance-identifier myoutpostdbinstance \
--engine-version 8.0.17 \
--db-instance-class db.m5.large \
--engine mysql \
--availability-zone us-east-1d \
```

```
--vpc-security-group-ids outpost-sg \
--db-subnet-group-name myoutpostdbsubnetgr \
--allocated-storage 100 \
--master-username masterawsuser \
--master-user-password masteruserpassword \
--backup-retention-period 3 \
--storage-encrypted \
--kms-key-id mykey
```

For Windows:

```
aws rds create-db-instance ^
--db-instance-identifier myoutpostdbinstance ^
--engine-version 8.0.17 ^
--db-instance-class db.m5.large ^
--engine mysql ^
--availability-zone us-east-1d ^
--vpc-security-group-ids outpost-sg ^
--db-subnet-group-name myoutpostdbsubnetgr ^
--allocated-storage 100 ^
--master-username masterawsuser ^
--master-user-password masteruserpassword ^
--backup-retention-period 3 ^
--storage-encrypted ^
--kms-key-id mykey
```

To create a PostgreSQL DB instance, specify `postgres` for the `--engine` option.

For information about each setting when creating a DB instance, see [Settings for DB instances \(p. 145\)](#).

RDS API

To create a new DB instance in an Outpost with the RDS API, first create a DB subnet group for use by RDS on Outposts by calling the [CreateDBSubnetGroup](#) operation. For `SubnetIds`, specify the subnet group in the Outpost for use by RDS on Outposts.

Next, call the [CreateDBInstance](#) operation with the parameters below. Specify an Availability Zone for the Outpost, an Amazon VPC security group associated with the Outpost, and the DB subnet group you created for the Outpost.

- `AllocatedStorage`
- `AvailabilityZone`
- `BackupRetentionPeriod`
- `DBInstanceState`
- `DBInstanceIdentifier`
- `VpcSecurityGroupIds`
- `DBSubnetGroupName`
- `Engine`
- `EngineVersion`
- `MasterUsername`
- `MasterUserPassword`
- `StorageEncrypted`
- `KmsKeyID`

For information about each setting when creating a DB instance, see [Settings for DB instances \(p. 145\)](#).

MariaDB on Amazon RDS

Amazon RDS supports DB instances running several versions of MariaDB. You can use the following major versions:

- MariaDB 10.5
- MariaDB 10.4
- MariaDB 10.3
- MariaDB 10.2
- MariaDB 10.1
- MariaDB 10.0

For more information about minor version support, see [MariaDB on Amazon RDS versions \(p. 576\)](#).

You first use the Amazon RDS management tools or interfaces to create a MariaDB DB instance. You can then use the Amazon RDS tools to perform management actions for the DB instance, such as reconfiguring or resizing the DB instance, authorizing connections to the DB instance, creating and restoring from backups or snapshots, creating Multi-AZ secondaries, creating read replicas, and monitoring the performance of the DB instance. You use standard MariaDB utilities and applications to store and access the data in the DB instance.

MariaDB is available in all of the AWS Regions. For more information about AWS Regions, see [Regions, Availability Zones, and Local Zones \(p. 49\)](#).

You can use Amazon RDS for MariaDB databases to build HIPAA-compliant applications. You can store healthcare-related information, including protected health information (PHI), under a Business Associate Agreement (BAA) with AWS. For more information, see [HIPAA compliance](#). AWS Services in Scope have been fully assessed by a third-party auditor and result in a certification, attestation of compliance, or Authority to Operate (ATO). For more information, see [AWS services in scope by compliance program](#).

Before creating your first DB instance, you should complete the steps in the setting up section of this guide. For more information, see [Setting up for Amazon RDS \(p. 67\)](#).

Common management tasks for MariaDB on Amazon RDS

The following are the common management tasks you perform with an Amazon RDS DB instance running MariaDB, with links to relevant documentation for each task.

Task area	Relevant documentation
Instance Classes, Storage, and PIOPS If you are creating a DB instance for production purposes, you should understand how instance classes, storage types, and Provisioned IOPS work in Amazon RDS.	DB instance classes (p. 7) Amazon RDS storage types (p. 40)
Multi-AZ Deployments Provide high availability with synchronous standby replication in a different Availability Zone, automatic failover, fault tolerance for DB instances using Multi-AZ deployments, and read replicas.	High availability (Multi-AZ) for Amazon RDS (p. 53)

Task area	Relevant documentation
Amazon Virtual Private Cloud (VPC) If your AWS account has a default VPC, then your DB instance is automatically created inside the default VPC. If your account does not have a default VPC, and you want the DB instance in a VPC, you must create the VPC and subnet groups before you create the DB instance.	Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1718) Working with a DB instance in a VPC (p. 1727)
Security Groups By default, DB instances are created with a firewall that prevents access to them. You therefore must create a security group with the correct IP addresses and network configuration to access the DB instance. The security group you create depends on what Amazon EC2 platform your DB instance is on, and whether you access your DB instance from an Amazon EC2 instance. In general, if your DB instance is on the <i>EC2-Classic</i> platform, you will need to create a DB security group; if your DB instance is on the <i>EC2-VPC</i> platform, you will need to create a VPC security group.	Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1718) Controlling access with security groups (p. 1699)
Parameter Groups If your DB instance is going to require specific database parameters, you should create a parameter group before you create the DB instance.	Working with DB parameter groups (p. 228)
Importing and Exporting Data Establish procedures for importing or exporting data.	Importing data into a MariaDB DB instance (p. 616)
Replication You can offload read traffic from your source MariaDB DB instance by creating read replicas.	Working with read replicas (p. 278)
Connecting to Your DB Instance Connect to your DB instance using a standard SQL client application.	Connecting to a DB instance running the MariaDB database engine (p. 588)
Backup and Restore When you create your DB instance, you can configure it to take automated backups. You can also back up and restore your databases manually by using full backup files (.bak files).	Working with backups (p. 328)
Monitoring Monitor your MariaDB DB instance by using Amazon CloudWatch RDS metrics, events, and Enhanced Monitoring. View log files for your MariaDB DB instance.	Viewing DB instance metrics (p. 548) Viewing Amazon RDS events (p. 503)
Log Files You can access the log files for your MariaDB DB instance.	Accessing Amazon RDS database log files (p. 504) MariaDB database log files (p. 508)

There are also advanced administrative tasks for working with DB instances running MariaDB. For more information, see the following documentation:

- [Parameters for MariaDB \(p. 620\)](#)
- [MariaDB on Amazon RDS SQL reference \(p. 625\)](#)

MariaDB on Amazon RDS versions

For MariaDB, version numbers are organized as version X.Y.Z. In Amazon RDS terminology, X.Y denotes the major version, and Z is the minor version number. For Amazon RDS implementations, a version change is considered major if the major version number changes, for example going from version 10.4 to 10.5. A version change is considered minor if only the minor version number changes, for example going from version 10.3.20 to 10.3.23.

Amazon RDS currently supports the following versions of MariaDB:

Major version	Minor version
MariaDB 10.5	<ul style="list-style-type: none">• 10.5.8 (supported in all AWS Regions)
MariaDB 10.4	<ul style="list-style-type: none">• 10.4.13 (supported in all AWS Regions)
MariaDB 10.3	<ul style="list-style-type: none">• 10.3.23 (supported in all AWS Regions)• 10.3.20 (supported in all AWS Regions)• 10.3.13 (supported in all AWS Regions)• 10.3.8 (supported in all AWS Regions)
MariaDB 10.2	<ul style="list-style-type: none">• 10.2.32 (supported in all AWS Regions)• 10.2.21 (supported in all AWS Regions)• 10.2.15 (supported in all AWS Regions)• 10.2.12 (supported in all AWS Regions)• 10.2.11 (supported in all AWS Regions)
MariaDB 10.1	<ul style="list-style-type: none">• 10.1.34 (supported in all AWS Regions)• 10.1.31 (supported in all AWS Regions)• 10.1.26 (supported in all AWS Regions)• 10.1.23 (supported in all AWS Regions)• 10.1.19 (supported in all AWS Regions)• 10.1.14 (supported in all AWS Regions except US East (Ohio))
MariaDB 10.0	<ul style="list-style-type: none">• 10.0.35 (supported in all AWS Regions)• 10.0.34 (supported in all AWS Regions)• 10.0.32 (supported in all AWS Regions)• 10.0.31 (supported in all AWS Regions)• 10.0.28 (supported in all AWS Regions)• 10.0.24 (supported in all AWS Regions)• 10.0.17 (supported in all AWS Regions except US East (Ohio), Canada (Central), and Europe (London))

You can specify any currently supported MariaDB version when creating a new DB instance. You can specify the major version (such as MariaDB 10.5), and any supported minor version for the specified

major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified. To see a list of supported versions, as well as defaults for newly created DB instances, use the [describe-db-engine-versions](#) AWS CLI command.

The default MariaDB version might vary by AWS Region. To create a DB instance with a specific minor version, specify the minor version during DB instance creation. You can determine the default minor version for an AWS Region using the following AWS CLI command:

```
aws rds describe-db-engine-versions --default-only --engine mariadb --engine-version major-engine-version --region region --query "*[].{Engine:Engine,EngineVersion:EngineVersion}" --output text
```

Replace *major-engine-version* with the major engine version, and replace *region* with the AWS Region. For example, the following AWS CLI command returns the default MariaDB minor engine version for the 10.3 major version and the US West (Oregon) AWS Region (us-west-2):

```
aws rds describe-db-engine-versions --default-only --engine mariadb --engine-version 10.3 --region us-west-2 --query '*[].{Engine:Engine,EngineVersion:EngineVersion}' --output text
```

Deprecation of MariaDB versions 10.0 and 10.1

On May 18, 2021, Amazon RDS plans to deprecate support for MariaDB 10.0 and 10.1 using the following schedule, which includes upgrade recommendations. For more information, see [Upgrading the MariaDB DB engine \(p. 598\)](#).

Action or recommendation	Dates
We recommend that you upgrade MariaDB 10.0 and 10.1 DB instances manually to the version of your choice.	Now–May 18, 2021
We recommend that you upgrade MariaDB 10.0 and 10.1 snapshots manually to the version of your choice.	Now–May 18, 2021
You can no longer create new MariaDB 10.0 and 10.1 DB instances.	December 3, 2020
Amazon RDS starts automatic upgrades of your MariaDB 10.0 and 10.1 DB instances to version 10.2.	March 22, 2021
Amazon RDS starts automatic upgrades to version 10.2 for any MariaDB 10.0 and 10.1 DB instances restored from snapshots.	March 22, 2021
Amazon RDS automatically upgrades any remaining MariaDB 10.0 and 10.1 DB instances to version 10.2 whether or not they are in a maintenance window.	May 18, 2021

For more information, see [Announcement: Extending end-of-life Process for Amazon RDS for MariaDB 10.0 and 10.1](#).

For information about the Amazon RDS deprecation policy for MariaDB, see [Amazon RDS FAQs](#).

MariaDB feature support on Amazon RDS

In the following sections, find MariaDB feature support on Amazon RDS for MariaDB major versions:

Topics

- [MariaDB 10.5 support on Amazon RDS \(p. 578\)](#)
- [MariaDB 10.4 support on Amazon RDS \(p. 579\)](#)
- [MariaDB 10.3 support on Amazon RDS \(p. 579\)](#)
- [MariaDB 10.2 support on Amazon RDS \(p. 579\)](#)
- [MariaDB 10.1 support on Amazon RDS \(p. 580\)](#)
- [MariaDB 10.0 support on Amazon RDS \(p. 580\)](#)

For information about supported minor versions of Amazon RDS for MariaDB, see [MariaDB on Amazon RDS versions \(p. 576\)](#).

MariaDB 10.5 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.5 or later:

- **InnoDB enhancements** – MariaDB version 10.5 includes InnoDB enhancements. For more information, see [InnoDB: Performance Improvements etc..](#)
- **Performance schema updates** – MariaDB version 10.5 includes performance schema updates. For more information, see [Performance Schema Updates to Match MySQL 5.7 Instrumentation and Tables](#).
- **One file in the InnoDB redo log** – In versions of MariaDB before version 10.5, the value of the `innodb_log_files_in_group` parameter was set to 2. In MariaDB version 10.5, the value of this parameter is set to 1.

If you are upgrading from a prior version to MariaDB version 10.5, and you don't modify the parameters, the `innodb_log_file_size` parameter value is unchanged. However, it applies to one log file instead of two. The result is that your upgraded MariaDB version 10.5 DB instance uses half of the redo log size that it was using before the upgrade. This change can have a noticeable performance impact. To address this issue, you can double the value of the `innodb_log_file_size` parameter. For information about modifying parameters, see [Modifying parameters in a DB parameter group \(p. 232\)](#).

- **SHOW SLAVE STATUS command not supported** – In versions of MariaDB before version 10.5, the `SHOW SLAVE STATUS` command required the `REPLICATION SLAVE` privilege. In MariaDB version 10.5, this command requires the `REPLICATION SLAVE ADMIN` privilege. This new privilege isn't granted to the RDS master user.

Instead of using the `SHOW SLAVE STATUS` command, run the new `mysql.rds_replica_status` stored procedure to return similar information. For more information, see [mysql.rds_replica_status \(p. 625\)](#).

- **SHOW RELAYLOG EVENTS command not supported** – In versions of MariaDB before version 10.5, the `SHOW RELAYLOG EVENTS` command required the `REPLICATION SLAVE` privilege. In MariaDB version 10.5, this command requires the `REPLICATION SLAVE ADMIN` privilege. This new privilege isn't granted to the RDS master user.
- **New default values for parameters** – The following parameters have new default values for MariaDB version 10.5 DB instances:
 - The default value of the `max_connections` parameter has changed to `LEAST({DBInstanceClassMemory/25165760}, 12000)`. For information about the `LEAST` parameter function, see [DB parameter functions \(p. 242\)](#).

- The default value of the `innodb_adaptive_hash_index` parameter has changed to `OFF` (0).
- The default value of the `innodb_checksum_algorithm` parameter has changed to `full_crc32`.
- The default value of the `innodb_log_file_size` parameter has changed to 2 GB.

For a list of all MariaDB 10.5 features and their documentation, see [Changes and improvements in MariaDB 10.5](#) and [Release notes - MariaDB 10.5 series](#) on the MariaDB website.

For a list of unsupported features, see [Features not supported \(p. 580\)](#).

MariaDB 10.4 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.4 or later:

- **User account security enhancements** – Password expiration and `account locking` improvements
- **Optimizer enhancements** – Optimizer trace feature
- **InnoDB enhancements** – Instant `DROP COLUMN` support and instant VARCHAR extension for `ROW_FORMAT=DYNAMIC` and `ROW_FORMAT=COMPACT`
- **New parameters** – Including `tcp_nodelay`, `tls_version`, and `gtid_cleanup_batch_size`

For a list of all MariaDB 10.4 features and their documentation, see [Changes and improvements in MariaDB 10.4](#) and [Release notes - MariaDB 10.4 series](#) on the MariaDB website.

For a list of unsupported features, see [Features not supported \(p. 580\)](#).

MariaDB 10.3 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.3 or later:

- **Oracle compatibility** – PL/SQL compatibility parser, sequences, `INTERSECT` and `EXCEPT` to complement `UNION`, new `TYPE OF` and `ROW TYPE OF` declarations, and invisible columns
- **Temporal data processing** – System versioned tables for querying of past and present states of the database
- **Flexibility** – User-defined aggregates, storage-independent column compression, and proxy protocol support to relay the client IP address to the server
- **Manageability** – Instant `ADD COLUMN` operations and fast-fail data definition language (DDL) operations

For a list of all MariaDB 10.3 features and their documentation, see [Changes & improvements in MariaDB 10.3](#) and [Release notes - MariaDB 10.3 series](#) on the MariaDB website.

For a list of unsupported features, see [Features not supported \(p. 580\)](#).

MariaDB 10.2 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.2 or later:

- `ALTER USER`
- Common Table Expressions

- Compressing Events to Reduce Size of the Binary Log
- CREATE USER — new options for limiting resource usage and TLS/SSL
- EXECUTE IMMEDIATE
- Flashback
- InnoDB — now the default storage engine instead of XtraDB
- InnoDB — set the buffer pool size dynamically
- JSON Functions
- Window Functions
- WITH

For a list of all MariaDB 10.2 features and their documentation, see [Changes & improvements in MariaDB 10.2](#) and [Release notes - MariaDB 10.2 series](#) on the MariaDB website.

For a list of unsupported features, see [Features not supported \(p. 580\)](#).

MariaDB 10.1 support on Amazon RDS

Amazon RDS supports the following new features for your DB instances running MariaDB version 10.1 or later:

- Optimistic in-order parallel replication
- Page Compression
- XtraDB data scrubbing and defragmentation

For a list of all MariaDB 10.1 features and their documentation, see [Changes & improvements in MariaDB 10.1](#) and [Release notes - MariaDB 10.1 series](#) on the MariaDB website.

For a list of unsupported features, see [Features not supported \(p. 580\)](#).

MariaDB 10.0 support on Amazon RDS

For a list of all MariaDB 10.0 features and their documentation, see [Changes & improvements in MariaDB 10.0](#) and [Release notes - MariaDB 10.0 series](#) on the MariaDB website.

For a list of unsupported features, see [Features not supported \(p. 580\)](#).

Features not supported

The following MariaDB features are not supported on Amazon RDS:

- ColumnStore storage engine
- S3 storage engine
- Authentication plugin – GSSAPI
- Authentication plugin – Unix Socket
- AWS Key Management encryption plugin
- Delayed replication

- Native MariaDB encryption at rest for XtraDB, InnoDB, and Aria.

You can enable encryption at rest for a MariaDB DB instance by following the instructions in [Encrypting Amazon RDS resources \(p. 1630\)](#).

- HandlerSocket
- JSON table type
- MariaDB ColumnStore
- MariaDB Galera Cluster
- Multisource replication
- MyRocks storage engine
- Password validation plugin, `simple_password_check`, and `cracklib_password_check`
- Spider storage engine
- Sphinx storage engine
- TokuDB storage engine
- Storage engine-specific object attributes, as described in [Engine-defined new Table/Field/Index attributes](#) in the MariaDB documentation
- Table and tablespace encryption

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection.

Supported storage engines for MariaDB on Amazon RDS

While MariaDB supports multiple storage engines with varying capabilities, not all of them are optimized for recovery and data durability. InnoDB (for version 10.2 and higher) and XtraDB (for version 10.0 and 10.1) are the recommended and supported storage engines for MariaDB DB instances on Amazon RDS. Amazon RDS features such as Point-In-Time Restore and snapshot restore require a recoverable storage engine and are supported only for the recommended storage engine for the MariaDB version. Amazon RDS also supports Aria, although using Aria might have a negative impact on recovery in the event of an instance failure. However, if you need to use spatial indexes to handle geographic data on MariaDB 10.1 or 10.0, you should use Aria because spatial indexes are not supported by XtraDB. On MariaDB 10.2 and higher, the InnoDB storage engine supports spatial indexes.

Other storage engines are not currently supported by Amazon RDS for MariaDB.

MariaDB file size limits in Amazon RDS

For MariaDB DB instances, the maximum provisioned storage limit constrains the size of a table to a maximum size of 16 TB when using InnoDB file-per-table tablespaces. This limit also constrains the system tablespace to a maximum size of 16 TB. InnoDB file-per-table tablespaces (with tables each in their own tablespace) are set by default for MariaDB DB instances. For more information, see [Amazon RDS DB instance storage \(p. 40\)](#).

There are advantages and disadvantages to using InnoDB file-per-table tablespaces, depending on your application. To determine the best approach for your application, see [File-per-table tablespaces](#) in the MySQL documentation.

We don't recommend allowing tables to grow to the maximum file size. In general, a better practice is to partition data into smaller tables, which can improve performance and recovery times.

One option that you can use for breaking a large table up into smaller tables is partitioning. *Partitioning* distributes portions of your large table into separate files based on rules that you specify. For example, if you store transactions by date, you can create partitioning rules that distribute older transactions into separate files using partitioning. Then periodically, you can archive the historical transaction data that doesn't need to be readily available to your application. For more information, see [Partitioning](#) in the MySQL documentation.

To determine the file size of a table

Use the following SQL command to determine if any of your tables are too large and are candidates for partitioning. To update table statistics, issue an `ANALYZE TABLE` command on each table. For more information, see [ANALYZE TABLE statement](#) in the MySQL documentation.

```
SELECT TABLE_SCHEMA, TABLE_NAME,
       round(((DATA_LENGTH + INDEX_LENGTH) / 1024 / 1024), 2) As "Approximate size (MB)",
       DATA_FREE
  FROM information_schema.TABLES
 WHERE TABLE_SCHEMA NOT IN ('mysql', 'information_schema', 'performance_schema');
```

To enable InnoDB file-per-table tablespaces

- To enable InnoDB file-per-table tablespaces, set the `innodb_file_per_table` parameter to 1 in the parameter group for the DB instance.

To disable InnoDB file-per-table tablespaces

- To disable InnoDB file-per-table tablespaces, set the `innodb_file_per_table` parameter to 0 in the parameter group for the DB instance.

For information on updating a parameter group, see [Working with DB parameter groups \(p. 228\)](#).

When you have enabled or disabled InnoDB file-per-table tablespaces, you can issue an `ALTER TABLE` command. You can use this command to move a table from the global tablespace to its own tablespace. Or you can move a table from its own tablespace to the global tablespace. Following is an example.

```
ALTER TABLE table_name ENGINE=InnoDB, ALGORITHM=COPY;
```

MariaDB security on Amazon RDS

Security for MariaDB DB instances is managed at three levels:

- AWS Identity and Access Management controls who can perform Amazon RDS management actions on DB instances. When you connect to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see [Identity and access management in Amazon RDS \(p. 1644\)](#).
- When you create a DB instance, you use either a VPC security group or a DB security group to control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB

instance. These connections can be made using Secure Socket Layer (SSL). In addition, firewall rules at your company can control whether devices running at your company can open connections to the DB instance.

- Once a connection has been opened to a MariaDB DB instance, authentication of the login and permissions are applied the same way as in a stand-alone instance of MariaDB. Commands such as `CREATE USER`, `RENAME USER`, `GRANT`, `REVOKE`, and `SET PASSWORD` work just as they do in stand-alone databases, as does directly modifying database schema tables.

When you create an Amazon RDS DB instance, the master user has the following default privileges:

- `alter`
- `alter routine`
- `create`
- `create routine`
- `create temporary tables`
- `create user`
- `create view`
- `delete`
- `drop`
- `event`
- `execute`
- `grant option`
- `index`
- `insert`
- `lock tables`
- `process`
- `references`
- `reload`

This privilege is limited on MariaDB DB instances. It doesn't grant access to the `FLUSH LOGS` or `FLUSH TABLES WITH READ LOCK` operations.

- `replication client`
- `replication slave`
- `select`
- `show databases`
- `show view`
- `trigger`
- `update`

For more information about these privileges, see [User account management](#) in the MariaDB documentation.

Note

Although you can delete the master user on a DB instance, we don't recommend doing so. To recreate the master user, use the `ModifyDBInstance` API or the `modify-db-instance` AWS CLI and specify a new master user password with the appropriate parameter. If the master user does not exist in the instance, the master user is created with the specified password.

To provide management services for each DB instance, the `rdsadmin` user is created when the DB instance is created. Attempting to drop, rename, change the password for, or change privileges for the `rdsadmin` account results in an error.

To allow management of the DB instance, the standard `kill` and `kill_query` commands have been restricted. The Amazon RDS commands `mysql.rds_kill`, `mysql.rds_kill_query`, and `mysql.rds_kill_query_id` are provided for use in MariaDB and also MySQL so that you can end user sessions or queries on DB instances.

Using SSL with a MariaDB DB instance

Amazon RDS supports Secure Sockets Layer (SSL) connections with DB instances running the MariaDB database engine.

Amazon RDS creates an SSL certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks.

For information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 1634\)](#).

MariaDB uses yaSSL for secure connections in the following versions:

- MariaDB version 10.1.26 and earlier 10.1 versions
- MariaDB version 10.0.32 and earlier 10.0 versions

MariaDB uses OpenSSL for secure connections in the following versions:

- MariaDB 10.5 versions
- MariaDB 10.4 versions
- MariaDB 10.3 versions
- MariaDB 10.2 versions
- MariaDB version 10.1.31 and later 10.1 versions
- MariaDB version 10.0.34 and later 10.0 versions

Amazon RDS for MariaDB supports Transport Layer Security (TLS) versions 1.0, 1.1, and 1.2. The following table shows the TLS support for MySQL versions.

MariaDB version	TLS 1.0	TLS 1.1	TLS 1.2
MariaDB 10.5	Supported	Supported	Supported
MariaDB 10.4	Supported	Supported	Supported
MariaDB 10.3	Supported	Supported	Supported
MariaDB 10.2	Supported	Supported	Supported
MariaDB 10.1	Supported	Supported for 10.1.31 and later 10.1 versions	Supported for 10.1.31 and later 10.1 versions

MariaDB version	TLS 1.0	TLS 1.1	TLS 1.2
MariaDB 10.0	Supported	Supported for 10.0.34 and later 10.0 versions	Supported for 10.0.34 and later 10.0 versions

To encrypt connections using the default mysql client, launch the mysql client using the --ssl-ca parameter to reference the public key, as shown in the examples following.

The following example shows how to launch the client using the --ssl-ca parameter for MariaDB 10.2 and later.

```
mysql -h myinstance.c9akciq32.rds-us-east-1.amazonaws.com  
--ssl-ca=[full path]rds-combined-ca-bundle.pem --ssl-mode=REQUIRED
```

The following example shows how to launch the client using the --ssl-ca parameter for MariaDB 10.1 and earlier.

```
mysql -h myinstance.c9akciq32.rds-us-east-1.amazonaws.com  
--ssl-ca=[full path]rds-combined-ca-bundle.pem --ssl-verify-server-cert
```

You can require SSL connections for specific users accounts. For example, you can use one of the following statements, depending on your MariaDB version, to require SSL connections on the user account `encrypted_user`.

For MariaDB 10.2 and later, use the following statement.

```
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

For MariaDB 10.1 and earlier, use the following statement.

```
GRANT USAGE ON *.* TO 'encrypted_user'@'%' REQUIRE SSL;
```

For more information on SSL connections with MariaDB, see [SSL overview](#) in the MariaDB documentation.

Cache warming

InnoDB (version 10.2 and later) and XtraDB (versions 10.0 and 10.1) cache warming can provide performance gains for your MariaDB DB instance by saving the current state of the buffer pool when the DB instance is shut down, and then reloading the buffer pool from the saved information when the DB instance starts up. This approach bypasses the need for the buffer pool to "warm up" from normal database use and instead preloads the buffer pool with the pages for known common queries. For more information on cache warming, see [Dumping and restoring the buffer pool](#) in the MariaDB documentation.

Cache warming is enabled by default on MariaDB 10.2 and higher DB instances. To enable it, set the `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup`

parameters to 1 in the parameter group for your DB instance. Changing these parameter values in a parameter group affects all MariaDB DB instances that use that parameter group. To enable cache warming for specific MariaDB DB instances, you might need to create a new parameter group for those DB instances. For information on parameter groups, see [Working with DB parameter groups \(p. 228\)](#).

Cache warming primarily provides a performance benefit for DB instances that use standard storage. If you use PIOPS storage, you don't commonly see a significant performance benefit.

Important

If your MariaDB DB instance doesn't shut down normally, such as during a failover, then the buffer pool state isn't saved to disk. In this case, MariaDB loads whatever buffer pool file is available when the DB instance is restarted. No harm is done, but the restored buffer pool might not reflect the most recent state of the buffer pool before the restart. To ensure that you have a recent state of the buffer pool available to warm the cache on startup, we recommend that you periodically dump the buffer pool "on demand." You can dump or load the buffer pool on demand.

You can create an event to dump the buffer pool automatically and at a regular interval. For example, the following statement creates an event named `periodic_buffer_pool_dump` that dumps the buffer pool every hour.

```
CREATE EVENT periodic_buffer_pool_dump
  ON SCHEDULE EVERY 1 HOUR
  DO CALL mysql.rds_innodb_buffer_pool_dump_now();
```

For more information, see [Events](#) in the MariaDB documentation.

Dumping and loading the buffer pool on demand

You can save and load the cache on demand using the following stored procedures:

- To dump the current state of the buffer pool to disk, call the [mysql.rds_innodb_buffer_pool_dump_now \(p. 971\)](#) stored procedure.
- To load the saved state of the buffer pool from disk, call the [mysql.rds_innodb_buffer_pool_load_now \(p. 971\)](#) stored procedure.
- To cancel a load operation in progress, call the [mysql.rds_innodb_buffer_pool_load_abort \(p. 972\)](#) stored procedure.

Database parameters for MariaDB

By default, a MariaDB DB instance uses a DB parameter group that is specific to a MariaDB database. This parameter group contains some but not all of the parameters contained in the Amazon RDS DB parameter groups for the MySQL database engine. It also contains a number of new, MariaDB-specific parameters. For more information on the parameters available for the RDS for MariaDB DB engine, see [Parameters for MariaDB \(p. 620\)](#).

Common DBA tasks for MariaDB

Ending sessions or queries, skipping replication errors, working with InnoDB (version 10.2 and later) and XtraDB (versions 10.0 and 10.1) tablespaces to improve crash recovery times, and managing the global status history are common DBA tasks you might perform in a MariaDB DB instance. You can handle these tasks just as in a MySQL DB instance, as described in [Common DBA tasks for MySQL DB](#)

[instances \(p. 933\)](#). The crash recovery instructions there refer to the MySQL InnoDB engine, but they are applicable to a MariaDB instance running InnoDB or XtraDB as well.

Local time zone for MariaDB DB instances

By default, the time zone for a MariaDB DB instance is Universal Time Coordinated (UTC). You can set the time zone for your DB instance to the local time zone for your application instead.

To set the local time zone for a DB instance, set the `time_zone` parameter in the parameter group for your DB instance to one of the supported values listed later in this section. When you set the `time_zone` parameter for a parameter group, all DB instances and read replicas that are using that parameter group change to use the new local time zone. For information on setting parameters in a parameter group, see [Working with DB parameter groups \(p. 228\)](#).

After you set the local time zone, all new connections to the database reflect the change. If you have any open connections to your database when you change the local time zone, you won't see the local time zone update until after you close the connection and open a new connection.

You can set a different local time zone for a DB instance and one or more of its read replicas. To do this, use a different parameter group for the DB instance and the replica or replicas and set the `time_zone` parameter in each parameter group to a different local time zone.

If you are replicating across AWS Regions, then the source DB instance and the read replica use different parameter groups (parameter groups are unique to an AWS Region). To use the same local time zone for each instance, you must set the `time_zone` parameter in the instance's and read replica's parameter groups.

When you restore a DB instance from a DB snapshot, the local time zone is set to UTC. You can update the time zone to your local time zone after the restore is complete. If you restore a DB instance to a point in time, then the local time zone for the restored DB instance is the time zone setting from the parameter group of the restored DB instance.

You can set your local time zone to one of the following values.

Africa/Cairo	Asia/Bangkok	Australia/Darwin
Africa/Casablanca	Asia/Beirut	Australia/Hobart
Africa/Harare	Asia/Calcutta	Australia/Perth
Africa/Monrovia	Asia/Damascus	Australia/Sydney

Connecting to a DB instance running the MariaDB database engine

After Amazon RDS provisions your DB instance, you can use any standard MariaDB client application or utility to connect to the instance. In the connection string, you specify the Domain Name System (DNS) address from the DB instance endpoint as the host parameter. You also specify the port number from the DB instance endpoint as the port parameter.

You can connect to an Amazon RDS for MariaDB DB instance by using tools like the mysql command line utility. For more information on using the mysql utility, see [mysql command-line client](#) in the MariaDB documentation. One GUI-based application that you can use to connect is Heidi. For more information, see the [Download heidi](#) page.

To connect to a DB instance from outside of a virtual private cloud (VPC) based on Amazon VPC, the DB instance must be publicly accessible. Also, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see [Can't connect to Amazon RDS DB instance \(p. 1746\)](#).

You can use SSL encryption on connections to a MariaDB DB instance. For information, see [Using SSL with a MariaDB DB instance \(p. 584\)](#).

Topics

- [Finding the connection information for a MariaDB DB instance \(p. 589\)](#)
- [Connecting from the mysql utility \(p. 591\)](#)

- [Connecting with SSL \(p. 592\)](#)
- [Troubleshooting connections to your MariaDB DB instance \(p. 592\)](#)

Finding the connection information for a MariaDB DB instance

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, suppose that an endpoint value is `mydb.123456789012.us-east-1.rds.amazonaws.com`. In this case, the port value is 3306, and the database user is `admin`. Given this information, you specify the following values in a connection string:

- For host or host name or DNS name, specify `mydb.123456789012.us-east-1.rds.amazonaws.com`.
- For port, specify 3306.
- For user, specify `admin`.

To connect to a DB instance, use any client for a DB engine. For example, you might use the `mysql` utility to connect to a MariaDB or MySQL DB instance. You might use Microsoft SQL Server Management Studio to connect to a SQL Server DB instance. You might use Oracle SQL Developer to connect to an Oracle DB instance, or the `psql` command line utility to connect to a PostgreSQL DB instance.

To find the connection information for a DB instance, you can use the AWS Management Console, the AWS Command Line Interface (AWS CLI) [describe-db-instances](#) command, or the Amazon RDS API [DescribeDBInstances](#) operation to list its details.

Console

To find the connection information for a DB instance in the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases** to display a list of your DB instances.
3. Choose the name of the MariaDB DB instance to display its details.
4. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

RDS > Databases > mydb

mydb

Summary

DB identifier	mydb	CPU	2.33%
Role	Instance	Current activity	0 Connections

Connectivity & security | Monitoring | Logs & events | Configuration

Connectivity & security

Endpoint & port	Network
Endpoint	Available
mydb. [REDACTED].us-east-1.rds.amazonaws.com	us-eas
Port	VPC
3306	vpc-65
Subnet	default
Security groups	[REDACTED]

5. If you need to find the master user name, choose the **Configuration** tab and view the **Master username** value.

AWS CLI

To find the connection information for a MariaDB DB instance by using the AWS CLI, call the [describe-db-instances](#) command. In the call, query for the DB instance ID, endpoint, port, and master user name.

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
--filters "Name=engine,Values=mariadb" \
--query "[].{DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername}"
```

For Windows:

```
aws rds describe-db-instances ^
--filters "Name=engine,Values=mariadb" ^
--query "[].{DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername}"
```

Your output should be similar to the following.

```
[  
  [  
    "mydb1",  
    "mydb1.123456789012.us-east-1.rds.amazonaws.com",  
    3306,  
    "admin"  
  ],  
  [  
    "mydb2",  
    "mydb2.123456789012.us-east-1.rds.amazonaws.com",  
    3306,  
    "admin"  
  ]  
]
```

RDS API

To find the connection information for a DB instance by using the Amazon RDS API, call the [DescribeDBInstances](#) operation. In the output, find the values for the endpoint address, endpoint port, and master user name.

Connecting from the mysql utility

To connect to a DB instance using the mysql utility, enter the following command at a command prompt on a client computer. Doing this connects you to a database on a MariaDB DB instance. Substitute the DNS name (endpoint) for your DB instance for `<endpoint>` and the master user name that you used for `<quartermaster>`. Provide the master password that you used when prompted for a password.

```
mysql -h <endpoint> -P 3306 -u <mymasteruser> -p
```

After you enter the password for the user, you see output similar to the following.

```
Welcome to the MySQL monitor. Commands end with ; or \g.  
Your MySQL connection id is 272  
Server version: 5.5.5-10.0.17-MariaDB-log MariaDB Server  
  
Copyright (c) 2000, 2015, Oracle and/or its affiliates. All rights reserved.  
  
Oracle is a registered trademark of Oracle Corporation and/or its  
affiliates. Other names may be trademarks of their respective  
owners.  
  
Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.
```

```
|mysql >
```

Connecting with SSL

Amazon RDS creates an SSL certificate for your DB instance when the instance is created. If you enable SSL certificate verification, then the SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks. To connect to your DB instance using SSL, follow these steps:

To connect to a DB instance with SSL using the mysql utility

1. Download a root certificate that works for all AWS Regions.

For information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 1634\)](#).

2. Enter the following command at a command prompt to connect to a DB instance with SSL using the mysql utility. For the -h parameter, substitute the DNS name for your DB instance. For the --ssl-ca parameter, substitute the SSL certificate file name as appropriate.

```
mysql -h mariadb-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=rds-ca-2015-root.pem -p
```

3. Include the --ssl-verify-server-cert parameter so that the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate. For example:

```
mysql -h mariadb-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=rds-ca-2015-root.pem --ssl-verify-server-cert -p
```

4. Enter the master user password when prompted.

You should see output similar to the following.

```
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 272
Server version: 5.5.5-10.0.17-MariaDB-log MariaDB Server

Copyright (c) 2000, 2015, Oracle and/or its affiliates. All rights reserved.

Oracle is a registered trademark of Oracle Corporation and/or its
affiliates. Other names may be trademarks of their respective
owners.

Type 'help;' or '\h' for help. Type '\c' to clear the current input statement.

mysql >
```

Troubleshooting connections to your MariaDB DB instance

Two common causes of connection failures to a new DB instance are the following:

- The DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the MariaDB application or utility is running. If the DB instance was created in an Amazon VPC, it must have a VPC security group that authorizes the connections. For more information, see [Amazon Virtual Private Cloud VPCs and Amazon RDS \(p. 1718\)](#).

You can add or edit an inbound rule in the security group. For **Source**, choose **My IP**. This allows access to the DB instance from the IP address detected in your browser.

If the DB instance was created outside of a VPC, it must have a DB security group that authorizes the connections.

- The DB instance was created using the default port of 3306, and your company has firewall rules blocking connections to that port from devices in your company network. To fix this failure, recreate the instance with a different port.

For more information on connection issues, see [Can't connect to Amazon RDS DB instance \(p. 1746\)](#).

Updating applications to connect to MariaDB DB instances using new SSL/TLS certificates

As of September 19, 2019, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether your applications require certificate verification to connect to your DB instances.

Note

Some applications are configured to connect to MariaDB only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.

You can specify the following SSL modes: `disabled`, `preferred`, and `required`. When you use the `preferred` SSL mode and the CA certificate doesn't exist or isn't up to date, the following behavior applies:

- For MariaDB version 10.2 and higher, and newer minor versions of 10.0 and 10.1, the connection falls back to not using SSL and still connects successfully.

Because these later versions use the OpenSSL protocol, an expired server certificate doesn't prevent successful connections unless the `required` SSL mode is specified.

- For older MariaDB 10.0 and 10.1 minor versions, an error is returned.

Because these older versions use the yaSSL protocol, certificate verification is strictly enforced and the connection is unsuccessful.

The following MariaDB minor versions use the yaSSL protocol:

- 10.0.17, 10.0.24, 10.0.28, 10.0.31, 10.0.32
- 10.1.14, 10.1.19, 10.1.23, 10.1.26

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see [Rotating your SSL/TLS certificate \(p. 1636\)](#). For more information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 1634\)](#). For information about using SSL/TLS with MariaDB DB instances, see [Using SSL with a MariaDB DB instance \(p. 584\)](#).

Topics

- [Determining whether a client requires certificate verification in order to connect \(p. 594\)](#)
- [Updating your application trust store \(p. 595\)](#)
- [Example Java code for establishing SSL connections \(p. 597\)](#)

Determining whether a client requires certificate verification in order to connect

You can check whether JDBC clients and MySQL clients require certificate verification to connect.

JDBC

The following example with MySQL Connector/J 8.0 shows one way to check an application's JDBC connection properties to determine whether successful connections require a valid certificate. For more information on all of the JDBC connection options for MySQL, see [Configuration properties](#) in the MySQL documentation.

When using the MySQL Connector/J 8.0, an SSL connection requires verification against the server CA certificate if your connection properties have `sslMode` set to `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);
```

Note

If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use SSL/TLS when connecting to your databases, these client drivers default to using SSL/TLS. In addition, when using SSL/TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.

MySQL

The following examples with the MySQL Client show two ways to check a script's MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see [Client-side configuration for encrypted connections](#) in the MySQL documentation.

When using the MySQL 5.7 or MySQL 8.0 Client, an SSL connection requires verification against the server CA certificate if for the `--ssl-mode` option you specify `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --
ssl-mode=VERIFY_CA
```

When using the MySQL 5.6 Client, an SSL connection requires verification against the server CA certificate if you specify the `--ssl-verify-server-cert` option, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --
ssl-verify-server-cert
```

Updating your application trust store

For information about updating the trust store for MySQL applications, see [Using TLS/SSL with MariaDB Connector/J](#) in the MariaDB documentation.

Note

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

Updating your application trust store for JDBC

You can update the trust store for applications that use JDBC for SSL/TLS connections.

To update the trust store for JDBC applications

1. Download the 2019 root certificate that works for all AWS Regions and put the file in the trust store directory.

For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 1634\)](#).

2. Convert the certificate to .der format using the following command.

```
openssl x509 -outform der -in rds-ca-2019-root.pem -out rds-ca-2019-root.der
```

Replace the file name with the one that you downloaded.

3. Import the certificate into the key store using the following command.

```
keytool -import -alias rds-root -keystore clientkeystore -file rds-ca-2019-root.der
```

4. Confirm that the key store was updated successfully.

```
keytool -list -v -keystore clientkeystore.jks
```

Enter the key store password when you are prompted for it.

Your output should contain the following.

```
rds-root,date, trustedCertEntry,  
Certificate fingerprint (SHA1):  
D4:0D:DB:29:E3:75:0D:FF:A6:71:C3:14:0B:BF:5F:47:8D:1C:80:96  
# This fingerprint should match the output from the below command  
openssl x509 -fingerprint -in rds-ca-2019-root.pem -noout
```

If you are using the MariaDB Connector/J JDBC driver in an application, set the following properties in the application.

```
System.setProperty("javax.net.ssl.trustStore", certs);  
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

When you start the application, set the following properties.

```
java -Djavax.net.ssl.trustStore=/path_to_truststore/MyTruststore.jks -  
Djavax.net.ssl.trustStorePassword=my_truststore_password com.companyName.MyApplication
```

Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection using JDBC.

```
private static final String DB_USER = "admin";  
  
private static final String DB_USER = "user name";  
private static final String DB_PASSWORD = "password";  
// This key store has only the prod root ca.  
private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";  
private static final String KEY_STORE_PASS = "keystore-password";  
  
public static void main(String[] args) throws Exception {  
    Class.forName("org.mariadb.jdbc.Driver");  
  
    System.setProperty("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);  
    System.setProperty("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);  
  
    Properties properties = new Properties();  
    properties.put("user", DB_USER);  
    properties.put("password", DB_PASSWORD);  
  
    Connection connection = DriverManager.getConnection("jdbc:mysql://ssl-mariadb-  
public.cn162e2e7kwh.us-east-1.rds.amazonaws.com:3306?useSSL=true", properties);  
    Statement stmt=connection.createStatement();  
  
    ResultSet rs=stmt.executeQuery("SELECT 1 from dual");  
  
    return;  
}
```

Important

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-2019 certificates. For instructions, see step 3 in [Updating your CA certificate by modifying your DB instance \(p. 1636\)](#).

Upgrading the MariaDB DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for MariaDB DB instances: major version upgrades and minor version upgrades.

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you follow the instructions in [Major version upgrades for MariaDB \(p. 599\)](#).

In contrast, *minor version upgrades* include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Or you can enable the **Auto minor version upgrade** option when creating or modifying a DB instance. Doing so means that your DB instance is automatically upgraded after Amazon RDS tests and approves the new version. For information about performing an upgrade, see [Upgrading a DB instance engine version \(p. 271\)](#).

If your MariaDB DB instance is using read replicas, you must upgrade all of the read replicas before upgrading the source instance. If your DB instance is in a Multi-AZ deployment, both the writer and standby replicas are upgraded. Your DB instance might not be available until the upgrade is complete.

For more information about MariaDB supported versions and version management, see [MariaDB on Amazon RDS versions \(p. 576\)](#).

Topics

- [Overview of upgrading \(p. 598\)](#)
- [Major version upgrades for MariaDB \(p. 599\)](#)
- [Upgrading a MariaDB DB instance \(p. 600\)](#)
- [Automatic minor version upgrades for MariaDB \(p. 600\)](#)

Overview of upgrading

When you use the AWS Management Console to upgrade a DB instance, it shows the valid upgrade targets for the DB instance. You can also use the following AWS CLI command to identify the valid upgrade targets for a DB instance:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mariadb \
--engine-version version-number \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine mariadb ^
--engine-version version-number ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For example, to identify the valid upgrade targets for a MariaDB version 10.1.19 DB instance, run the following AWS CLI command:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mariadb \
--engine-version 10.1.19 \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine mariadb ^
--engine-version 10.1.19 ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the DB instance before any upgrade changes have been made. If the upgrade doesn't work for your databases, you can restore this snapshot to create a DB instance running the old version. The second DB snapshot is taken when the upgrade completes.

Note

Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

After the upgrade is complete, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore the first DB snapshot taken to create a new DB instance.

You control when to upgrade your DB instance to a new version supported by Amazon RDS. This level of control helps you maintain compatibility with specific database versions and test new versions with your application before deploying in production. When you are ready, you can perform version upgrades at the times that best fit your schedule.

If your DB instance is using read replication, you must upgrade all of the Read Replicas before upgrading the source instance.

If your DB instance is in a Multi-AZ deployment, both the primary and standby DB instances are upgraded. The primary and standby DB instances are upgraded at the same time and you will experience an outage until the upgrade is complete. The time for the outage varies based on your database engine, engine version, and the size of your DB instance.

Major version upgrades for MariaDB

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, Amazon RDS doesn't apply major version upgrades automatically. You must manually modify your DB instance. We recommend that you thoroughly test any upgrade before applying it to your production instances.

Amazon RDS supports the following in-place upgrades for major versions of the MariaDB database engine:

- MariaDB 10.0 to MariaDB 10.1
- MariaDB 10.1 to MariaDB 10.2

- MariaDB 10.2 to MariaDB 10.3
- MariaDB 10.3 to MariaDB 10.4
- MariaDB 10.4 to MariaDB 10.5

To perform a major version upgrade for a MariaDB version 10.0 DB instance on Amazon RDS to MariaDB version 10.1 or later, first upgrade to each major version: 10.0 to 10.1, then 10.1 to 10.2, then 10.2 to 10.3, 10.3 to 10.4, and then 10.4 to 10.5.

If you are using a custom parameter group, and you perform a major version upgrade, you must specify either a default parameter group for the new DB engine version or create your own custom parameter group for the new DB engine version. Associating the new parameter group with the DB instance requires a customer-initiated database reboot after the upgrade completes. The instance's parameter group status will show pending-reboot if the instance needs to be rebooted to apply the parameter group changes. An instance's parameter group status can be viewed in the AWS console or by using a "describe" call such as `describe-db-instances`.

Upgrading a MariaDB DB instance

For information about manually or automatically upgrading a MariaDB DB instance, see [Upgrading a DB instance engine version \(p. 271\)](#).

Automatic minor version upgrades for MariaDB

If you specify the following settings when creating or modifying a DB instance, you can have your DB instance automatically upgraded.

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.

For more information about these settings, see [Settings for DB instances \(p. 251\)](#).

For some RDS for MariaDB major versions in some AWS Regions, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
- Bugs in the MySQL community version
- Overall fleet stability since the minor version was released

You can use the following AWS CLI command and script to determine the current automatic minor upgrade target version for a specified MariaDB minor version in a specific AWS Region.

```
aws rds describe-db-engine-versions --output=table --engine mariadb --engine-version minor-version --region region
```

For example, the following AWS CLI command determines the automatic minor upgrade target for MariaDB minor version 10.2.11 in the US East (Ohio) AWS Region (us-east-2).

```
aws rds describe-db-engine-versions --output=table --engine mariadb --engine-version 10.2.11 --region us-east-2
```

Your output is similar to the following.

DescribeDBEngineVersions								
<hr/>								
<hr/>								
<hr/>								
DBEngineVersions								
<hr/>								
<hr/>								
<hr/>								
DBEngineDescription	MariaDb Community Edition							
DBEngineVersionDescription	MariaDB 10.2.11							
DBParameterGroupFamily	mariadb10.2							
Engine	mariadb							
EngineVersion	10.2.11							
Status	available							
SupportsGlobalDatabases	False							
SupportsExportsToCloudwatchLogs	True							
SupportsParallelQuery	False							
SupportsReadReplica	True							
<hr/>								
<hr/>								
<hr/>								
ExportableLogTypes								
<hr/>								
<hr/>								
<hr/>								
audit								
error								
general								
slowquery								
<hr/>								
<hr/>								
<hr/>								
ValidUpgradeTarget								
<hr/>								
<hr/>								
<hr/>								
AutoUpgrade	Description	Engine	EngineVersion	IsMajorVersionUpgrade				
False	MariaDB 10.2.12	mariadb	10.2.12	False				
False	MariaDB 10.2.15	mariadb	10.2.15	False				
True	MariaDB 10.2.21	mariadb	10.2.21	False				
False	MariaDB 10.3.8	mariadb	10.3.8	True				
False	MariaDB 10.3.20	mariadb	10.3.20	True				

False	MariaDB 10.3.23 mariadb 10.3.23	True
	-----+-----+-----+-----+	
+		

In this example, the `AutoUpgrade` value is `True` for MariaDB version 10.2.21. So, the automatic minor upgrade target is MariaDB version 10.2.21, which is highlighted in the output.

A MariaDB DB instance is automatically upgraded during your maintenance window if the following criteria are met:

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.
- The DB instance is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see [Automatically upgrading the minor engine version \(p. 273\)](#).

Migrating data from a MySQL DB snapshot to a MariaDB DB instance

You can migrate an RDS for MySQL DB snapshot to a new DB instance running MariaDB 10.1 using the AWS CLI or Amazon RDS API. You must create the DB snapshot from an Amazon RDS DB instance running MySQL 5.6. To learn how to create an RDS for MySQL DB snapshot, see [Creating a DB snapshot \(p. 346\)](#).

After you migrate from MySQL to MariaDB, the MariaDB DB instance will be associated with the default DB parameter group and option group. After you restore the DB snapshot, you can associate a custom DB parameter group for the new DB instance. However, a MariaDB parameter group has a different set of configurable system variables. For information about the differences between MySQL and MariaDB system variables, see [System variable differences between MariaDB 10.1 and MySQL 5.6](#). To learn about DB parameter groups, see [Working with DB parameter groups \(p. 228\)](#). To learn about option groups, see [Working with option groups \(p. 212\)](#).

Incompatibilities between MariaDB and MySQL

Incompatibilities between MySQL and MariaDB include the following:

- You can't migrate a DB snapshot created with MySQL 5.5 to MariaDB 10.1.
- You can't migrate a DB snapshot created with MySQL 5.7 to MariaDB.
- You can't migrate a DB snapshot created with MySQL 8.0 to MariaDB.
- You can't migrate an encrypted snapshot.
- If the source MySQL database uses a SHA256 password hash, you need to reset user passwords that are SHA256 hashed before you can connect to the MariaDB database. The following code shows how to reset a password that is SHA256 hashed:

```
SET old_passwords = 0;
UPDATE mysql.user SET plugin = 'mysql_native_password',
Password = PASSWORD('new_password')
WHERE (User, Host) = ('master_user_name', %);
FLUSH PRIVILEGES;
```

- If your RDS master user account uses the SHA-256 password hash, you must reset the password using the AWS Management Console, the [modify-db-instance](#) AWS CLI command, or the [ModifyDBInstance](#) RDS API operation. For information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).
- MariaDB doesn't support the Memcached plugin; however, the data used by the Memcached plugin is stored as InnoDB tables. After you migrate a MySQL DB snapshot, you can access the data used by the Memcached plugin using SQL. For more information about the innodb_memcache database, see [InnoDB memcached plugin internals](#).

Performing the migration

You can migrate an RDS for MySQL DB snapshot to a new MariaDB DB instance using the AWS CLI or the RDS API.

Note

You can't use the AWS Management Console to migrate an RDS for MySQL DB snapshot to a new MariaDB DB instance.

AWS CLI

To migrate data from a MySQL DB snapshot to a MariaDB DB instance, use the AWS CLI [restore-db-instance-from-db-snapshot](#) command with the following parameters:

- `--db-instance-identifier` – Name of the DB instance to create from the DB snapshot.
- `--db-snapshot-identifier` – The identifier for the DB snapshot to restore from.
- `--engine` – The database engine to use for the new instance.

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \
  --db-instance-identifier newmariadbinstance \
  --db-snapshot-identifier mysqlsnapshot \
  --engine mariadb
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^
  --db-instance-identifier newmariadbinstance ^
  --db-snapshot-identifier mysqlsnapshot ^
  --engine mariadb
```

API

To migrate data from a MySQL DB snapshot to a MariaDB DB instance, call the Amazon RDS API operation [RestoreDBInstanceFromDBSnapshot](#).

Working with MariaDB replication in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see [Working with read replicas \(p. 278\)](#). For specific information about working with read replicas on Amazon RDS for MariaDB, see [Working with MariaDB read replicas \(p. 605\)](#).

You can also configure replication based on binary log coordinates for a MariaDB DB instance. For MariaDB instances, you can also configure replication based on global transaction IDs (GTIDs), which provides better crash safety. For more information, see [Configuring GTID-based replication into a MariaDB DB instance \(p. 613\)](#).

The following are other replication options available with Amazon RDS for MariaDB:

- You can set up replication between an Amazon RDS for MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS. For information about configuring replication with an external source, see [Replication with a MySQL or MariaDB instance running external to Amazon RDS \(p. 914\)](#).
- You can configure replication to import databases from a MySQL or MariaDB instance that is external to Amazon RDS, or to export databases to such instances. For more information, see [Importing data to an Amazon RDS MySQL or MariaDB DB instance with reduced downtime \(p. 881\)](#) and [Exporting data from a MySQL DB instance by using replication \(p. 921\)](#).

For any of these replication options, you can use either row-based replication, statement-based, or mixed replication. Row-based replication only replicates the changed rows that result from a SQL statement. Statement-based replication replicates the entire SQL statement. Mixed replication uses statement-based replication when possible, but switches to row-based replication when SQL statements that are unsafe for statement-based replication are run. In most cases, mixed replication is recommended. The binary log format of the DB instance determines whether replication is row-based, statement-based, or mixed. For information about setting the binary log format, see [Binary logging format \(p. 513\)](#).

Working with MariaDB read replicas

This section contains specific information about working with read replicas on Amazon RDS for MariaDB. For general information about read replicas and instructions for using them, see [Working with read replicas \(p. 278\)](#).

Topics

- [Read replica configuration with MariaDB \(p. 606\)](#)
- [Configuring replication filters with MariaDB \(p. 606\)](#)
- [Read replica updates with MariaDB \(p. 611\)](#)
- [Multi-AZ read replica deployments with MariaDB \(p. 611\)](#)
- [Monitoring MariaDB read replicas \(p. 611\)](#)
- [Starting and stopping replication with MariaDB read replicas \(p. 612\)](#)
- [Troubleshooting a MariaDB read replica problem \(p. 612\)](#)

Read replica configuration with MariaDB

Before a MariaDB DB instance can serve as a replication source, you must enable automatic backups on the source DB instance by setting the backup retention period to a value other than 0. This requirement also applies to a read replica that is the source DB instance for another read replica.

You can create up to five read replicas from one DB instance. For replication to operate effectively, each read replica should have as the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

If a read replica is running any version of MariaDB, you can specify it as the source DB instance for another read replica. For example, you can create ReadReplica1 from MyDBInstance, and then create ReadReplica2 from ReadReplica1. Updates made to MyDBInstance are replicated to ReadReplica1 and then replicated from ReadReplica1 to ReadReplica2. You can't have more than four instances involved in a replication chain. For example, you can create ReadReplica1 from MySourceDBInstance, and then create ReadReplica2 from ReadReplica1, and then create ReadReplica3 from ReadReplica2, but you can't create a ReadReplica4 from ReadReplica3.

If you promote a MariaDB read replica that is in turn replicating to other read replicas, those read replicas remain active. Consider an example where MyDBInstance1 replicates to MyDBInstance2, and MyDBInstance2 replicates to MyDBInstance3. If you promote MyDBInstance2, replication from MyDBInstance1 to MyDBInstance2 no longer occurs, but MyDBInstance2 still replicates to MyDBInstance3.

To enable automatic backups on a read replica for Amazon RDS for MariaDB, first create the read replica, then modify the read replica to enable automatic backups.

You can run multiple concurrent read replica create or delete actions that reference the same source DB instance, as long as you stay within the limit of five read replicas for the source instance.

Configuring replication filters with MariaDB

You can use replication filters to specify which databases and tables are replicated with a read replica. Replication filters can include databases and tables in replication or exclude them from replication.

The following are some use cases for replication filters:

- To reduce the size of a read replica. With replication filtering, you can exclude the databases and tables that aren't needed on the read replica.
- To exclude databases and tables from read replicas for security reasons.
- To replicate different databases and tables for specific use cases at different read replicas. For example, you might use specific read replicas for analytics or sharding.
- For a DB instance that has read replicas in different AWS Regions, to replicate different databases or tables in different AWS Regions.

Topics

- [Replication filtering parameters for Amazon RDS for MariaDB \(p. 606\)](#)
- [Replication filtering limitations for Amazon RDS for MariaDB \(p. 607\)](#)
- [Replication filtering examples for Amazon RDS for MariaDB \(p. 608\)](#)
- [Viewing the replication filters for a read replica \(p. 611\)](#)

Replication filtering parameters for Amazon RDS for MariaDB

To configure replication filters, set the following replication filtering parameters on the read replica:

- `replicate-do-db` – Replicate changes to the specified databases. When you set this parameter for a read replica, only the databases specified in the parameter are replicated.
- `replicate-ignore-db` – Don't replicate changes to the specified databases. When the `replicate-do-db` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-do-table` – Replicate changes to the specified tables. When you set this parameter for a read replica, only the tables specified in the parameter are replicated. Also, when the `replicate-do-db` or `replicate-ignore-db` parameter is set, the database that includes the specified tables must be included in replication with the read replica.
- `replicate-ignore-table` – Don't replicate changes to the specified tables. When the `replicate-do-table` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-wild-do-table` – Replicate tables based on the specified database and table name patterns. The % and _ wildcard characters are supported. When the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- `replicate-wild-ignore-table` – Don't replicate tables based on the specified database and table name patterns. The % and _ wildcard characters are supported. When the `replicate-do-table` or `replicate-wild-do-table` parameter is set for a read replica, this parameter isn't evaluated.

The parameters are evaluated in the order that they are listed. For more information about how these parameters work, see [the MariaDB documentation](#).

By default, each of these parameters has an empty value. On each read replica, you can use these parameters to set, change, and delete replication filters. When you set one of these parameters, separate each filter from others with a comma.

You can use the % and _ wildcard characters in the `replicate-wild-do-table` and `replicate-wild-ignore-table` parameters. The % wildcard matches any number of characters, and the _ wildcard matches only one character.

The binary logging format of the source DB instance is important for replication because it determines the record of data changes. The setting of the `binlog_format` parameter determines whether the replication is row-based or statement-based. For more information, see [Binary logging format \(p. 513\)](#).

Note

All data definition language (DDL) statements are replicated as statements, regardless of the `binlog_format` setting on the source DB instance.

Replication filtering limitations for Amazon RDS for MariaDB

The following limitations apply to replication filtering for Amazon RDS for MariaDB:

- Each replication filtering parameter has a 2,000-character limit.
- Commas aren't supported in replication filters.
- The MariaDB `binlog_do_db` and `binlog_ignore_db` options for binary log filtering aren't supported.
- Replication filtering doesn't support XA transactions.

For more information, see [Restrictions on XA Transactions](#) in the MySQL documentation.

- Replication filtering is supported for Amazon RDS for MariaDB version 10.3.13 and higher 10.3 versions, all 10.4 versions, and all 10.5 versions.
- Replication filtering isn't supported for Amazon RDS for MariaDB version 10.0, 10.1, and 10.2.

Replication filtering examples for Amazon RDS for MariaDB

To configure replication filtering for a read replica, modify the replication filtering parameters in the parameter group associated with the read replica.

Note

You can't modify a default parameter group. If the read replica is using a default parameter group, create a new parameter group and associate it with the read replica. For more information on DB parameter groups, see [Working with DB parameter groups \(p. 228\)](#).

You can set parameters in a parameter group using the AWS Management Console, AWS CLI, or RDS API. For information about setting parameters, see [Modifying parameters in a DB parameter group \(p. 232\)](#). When you set parameters in a parameter group, all of the DB instances associated with the parameter group use the parameter settings. If you set the replication filtering parameters in a parameter group, make sure that the parameter group is associated only with read replicas. Leave the replication filtering parameters empty for source DB instances.

The following examples set the parameters using the AWS CLI. These examples set `ApplyMethod` to `immediate` so that the parameter changes occur immediately after the CLI command completes. If you want a pending change to be applied after the read replica is rebooted, set `ApplyMethod` to `pending-reboot`.

The following examples set replication filters:

- [Including databases in replication](#)
- [Including tables in replication](#)
- [Including tables in replication with wildcard characters](#)
- [Escaping wildcard characters in names](#)
- [Excluding databases from replication](#)
- [Excluding tables from replication](#)
- [Excluding tables from replication using wildcard characters](#)

Example Including databases in replication

The following example includes the `mydb1` and `mydb2` databases in replication. When you set `replicate-do-db` for a read replica, only the databases specified in the parameter are replicated.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "[{"ParameterName": "replicate-do-db", "ParameterValue": "mydb1,mydb2",
"ApplyMethod": "immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
--parameters "[{"ParameterName": "replicate-do-db", "ParameterValue": "mydb1,mydb2",
"ApplyMethod": "immediate"}]"
```

Example Including tables in replication

The following example includes the `table1` and `table2` tables in database `mydb1` in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "[{"ParameterName": "replicate-do-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
--parameters "[{"ParameterName": "replicate-do-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"}]"
```

Example Including tables in replication using wildcard characters

The following example includes tables with names that begin with `orders` and `returns` in database `mydb` in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue": "mydb.orders%,mydb_returns%", "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
--parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue": "mydb.orders%,mydb_returns%", "ApplyMethod":"immediate"}]"
```

Example Escaping wildcard characters in names

The following example shows you how to use the escape character `\` to escape a wildcard character that is part of a name.

Assume that you have several table names in database `mydb1` that start with `my_table`, and you want to include these tables in replication. The table names include an underscore, which is also a wildcard character, so the example escapes the underscore in the table names.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue": "my\_table%", "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
--parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue": "my\_table%", "ApplyMethod":"immediate"}]"
```

Example Excluding databases from replication

The following example excludes the `mydb1` and `mydb2` databases from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "[{"ParameterName": "replicate-ignore-db", "ParameterValue": "mydb1,mydb2",
"ApplyMethod": "immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
--parameters "[{"ParameterName": "replicate-ignore-db", "ParameterValue": "mydb1,mydb2",
"ApplyMethod": "immediate"}]"
```

Example Excluding tables from replication

The following example excludes tables `table1` and `table2` in database `mydb1` from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "[{"ParameterName": "replicate-ignore-table", "ParameterValue": "mydb1.table1,mydb1.table2",
"ApplyMethod": "immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
--parameters "[{"ParameterName": "replicate-ignore-table", "ParameterValue": "mydb1.table1,mydb1.table2",
"ApplyMethod": "immediate"}]"
```

Example Excluding tables from replication using wildcard characters

The following example excludes tables with names that begin with `orders` and `returns` in database `mydb` from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "[{"ParameterName": "replicate-wild-ignore-table", "ParameterValue": "mydb.orders%,mydb>Returns%",
"ApplyMethod": "immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
```

```
--parameters "[{"ParameterName": "replicate-wild-ignore-table", "ParameterValue": "mydb.orders%,mydb.returns%", "ApplyMethod":"immediate"}]"
```

Viewing the replication filters for a read replica

You can view the replication filters for a read replica in the following ways:

- Check the settings of the replication filtering parameters in the parameter group associated with the read replica.

For instructions, see [Viewing parameter values for a DB parameter group \(p. 239\)](#).

- In a MariaDB client, connect to the read replica and run the `SHOW SLAVE STATUS` statement.

In the output, the following fields show the replication filters for the read replica:

- `Replicate_Do_DB`
- `Replicate_Ignore_DB`
- `Replicate_Do_Table`
- `Replicate_Ignore_Table`
- `Replicate_Wild_Do_Table`
- `Replicate_Wild_Ignore_Table`

For more information about these fields, see [Checking Replication Status](#) in the MySQL documentation.

Read replica updates with MariaDB

Read replicas are designed to support read queries, but you might need occasional updates. For example, you might need to add an index to speed the specific types of queries accessing the replica. You can enable updates by setting the `read_only` parameter to `0` in the DB parameter group for the read replica.

Multi-AZ read replica deployments with MariaDB

You can create a read replica from either single-AZ or Multi-AZ DB instance deployments. You use Multi-AZ deployments to improve the durability and availability of critical data, but you can't use the Multi-AZ secondary to serve read-only queries. Instead, you can create read replicas from high-traffic Multi-AZ DB instances to offload read-only queries. If the source instance of a Multi-AZ deployment fails over to the secondary, any associated read replicas automatically switch to use the secondary (now primary) as their replication source. For more information, see [High availability \(Multi-AZ\) for Amazon RDS \(p. 53\)](#).

You can create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

Monitoring MariaDB read replicas

For MariaDB read replicas, you can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric. The `ReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the `SHOW SLAVE STATUS` command.

Common causes for replication lag for MariaDB are the following:

- A network outage.
- Writing to tables with indexes on a read replica. If the `read_only` parameter is not set to `0` on the read replica, it can break replication.

- Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB storage engine on MariaDB 10.2 and later and the XtraDB storage engine on MariaDB 10.1 and earlier.

When the `ReplicaLag` metric reaches 0, the replica has caught up to the source DB instance. If the `ReplicaLag` metric returns -1, then replication is currently not active. `ReplicaLag = -1` is equivalent to `Seconds_Behind_Master = NULL`.

Starting and stopping replication with MariaDB read replicas

You can stop and restart the replication process on an Amazon RDS DB instance by calling the system stored procedures [mysql.rds_stop_replication \(p. 967\)](#) and [mysql.rds_start_replication \(p. 964\)](#). You can do this when replicating between two Amazon RDS instances for long-running operations such as creating large indexes. You also need to stop and start replication when importing or exporting databases. For more information, see [Importing data to an Amazon RDS MySQL or MariaDB DB instance with reduced downtime \(p. 881\)](#) and [Exporting data from a MySQL DB instance by using replication \(p. 921\)](#).

If replication is stopped for more than 30 consecutive days, either manually or due to a replication error, Amazon RDS ends replication between the source DB instance and all read replicas. It does so to prevent increased storage requirements on the source DB instance and long failover times. The read replica DB instance is still available. However, replication can't be resumed because the binary logs required by the read replica are deleted from the source DB instance after replication is ended. You can create a new read replica for the source DB instance to reestablish replication.

Troubleshooting a MariaDB read replica problem

The replication technologies for MariaDB are asynchronous. Because they are asynchronous, occasional `BinLogDiskUsage` increases on the source DB instance and `ReplicaLag` on the read replica are to be expected. For example, a high volume of write operations to the source DB instance can occur in parallel. In contrast, write operations to the read replica are serialized using a single I/O thread, which can lead to a lag between the source instance and read replica. For more information about read-only replicas in the MariaDB documentation, go to [Replication overview](#).

You can do several things to reduce the lag between updates to a source DB instance and the subsequent updates to the read replica, such as the following:

- Sizing a read replica to have a storage size and DB instance class comparable to the source DB instance.
- Ensuring that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter later in this section.

Amazon RDS monitors the replication status of your read replicas and updates the `Replication State` field of the read replica instance to `Error` if replication stops for any reason. An example might be if DML queries run on your read replica conflict with the updates made on the source DB instance.

You can review the details of the associated error thrown by the MariaDB engine by viewing the `Replication_Error` field. Events that indicate the status of the read replica are also generated, including [RDS-EVENT-0045 \(p. 492\)](#), [RDS-EVENT-0046 \(p. 492\)](#), and [RDS-EVENT-0047 \(p. 491\)](#). For more information about events and subscribing to events, see [Using Amazon RDS event notification \(p. 487\)](#). If a MariaDB error message is returned, review the error in the [MariaDB error message documentation](#).

One common issue that can cause replication errors is when the value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance. The `max_allowed_packet` parameter is a custom parameter that you can set in a DB

parameter group that is used to specify the maximum size of DML code that can be run on the database. In some cases, the `max_allowed_packet` parameter value in the DB parameter group associated with a source DB instance is smaller than the `max_allowed_packet` parameter value in the DB parameter group associated with the source's read replica. In these cases, the replication process can throw an error (Packet bigger than '`max_allowed_packet`' bytes) and stop replication. You can fix the error by having the source and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.

Other common situations that can cause replication errors include the following:

- Writing to tables on a read replica. If you are creating indexes on a read replica, you need to have the `read_only` parameter set to **0** to create the indexes. If you are writing to tables on the read replica, it might break replication.
- Using a non-transactional storage engine such as MyISAM. read replicas require a transactional storage engine. Replication is only supported for the InnoDB storage engine on MariaDB 10.2 and later and the XtraDB storage engine on MariaDB 10.1 and earlier.
- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see [Determination of safe and unsafe statements in binary logging](#).

If you decide that you can safely skip an error, you can follow the steps described in the section [Skipping the current replication error \(p. 933\)](#). Otherwise, you can delete the read replica and create an instance using the same DB instance identifier so that the endpoint remains the same as that of your old read replica. If a replication error is fixed, the `Replication State` changes to *replicating*.

For MariaDB DB instances, in some cases read replicas can't be switched to the secondary if some binlog events aren't flushed during the failure. In these cases, you must manually delete and recreate the read replicas. You can reduce the chance of this happening by setting the following parameter values: `sync_binlog=1` and `innodb_flush_log_at_trx_commit=1`. These settings might reduce performance, so test their impact before implementing the changes in a production environment.

Configuring GTID-based replication into a MariaDB DB instance

You can set up replication based on global transaction identifiers (GTIDs) from an external MariaDB instance of version 10.0.24 or greater into a MariaDB DB instance. Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:

- Monitor failover events for the Amazon RDS for MariaDB DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see [Using Amazon RDS event notification \(p. 487\)](#).
- Maintain the binlogs on your source instance until you have verified that they have been applied to the replica. This maintenance ensures that you can restore your source instance in the event of a failure.
- Turn on automated backups on your MariaDB DB instance on Amazon RDS. Turning on automated backups ensures that you can restore your replica to a particular point in time if you need to resynchronize your source instance and replica. For information on backups and Point-In-Time Restore, see [Backing up and restoring an Amazon RDS DB instance \(p. 327\)](#).

Note

The permissions required to start replication on a MariaDB DB instance are restricted and not available to your Amazon RDS master user. Because of this, you must use the Amazon RDS `mysql.rds_set_external_master_gtid` (p. 626) and `mysql.rds_start_replication` (p. 964) commands to set up replication between your live database and your Amazon RDS for MariaDB database.

To start replication between an external source instance and a MariaDB DB instance on Amazon RDS, use the following procedure.

To start replication

1. Make the source MariaDB instance read-only:

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

2. Get the current GTID of the external MariaDB instance. You can do this by using mysql or the query editor of your choice to run `SELECT @@gtid_current_pos;`.

The GTID is formatted as <domain-id>-<server-id>-<sequence-id>. A typical GTID looks something like **0-1234510749-1728**. For more information about GTIDs and their component parts, see [Global transaction ID](#) in the MariaDB documentation.

3. Copy the database from the external MariaDB instance to the MariaDB DB instance using mysqldump. For very large databases, you might want to use the procedure in [Importing data to an Amazon RDS MySQL or MariaDB DB instance with reduced downtime \(p. 881\)](#).

Note

Make sure there is not a space between the `-p` option and the entered password.

For Linux, macOS, or Unix:

```
mysqldump \
--databases <database_name> \
--single-transaction \
--compress \
--order-by-primary \
-u <local_user> \
-p<local_password> | mysql \
--host=hostname \
--port=3306 \
-u <RDS_user_name> \
-p <RDS_password>
```

For Windows:

```
mysqldump ^
--databases <database_name> ^
--single-transaction ^
--compress ^
--order-by-primary \
-u <local_user> \
-p<local_password> | mysql ^
--host=hostname ^
--port=3306 ^
-u <RDS_user_name> ^
-p <RDS_password>
```

Use the `--host`, `--user` (`-u`), `--port` and `-p` options in the mysql command to specify the host name, user name, port, and password to connect to your MariaDB DB instance. The host name is the DNS name from the MariaDB DB instance endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the [Amazon RDS Management Console](#).

4. Make the source MariaDB instance writeable again.

```
mysql> SET GLOBAL read_only = OFF;
```

```
mysql> UNLOCK TABLES;
```

5. In the Amazon RDS Management Console, add the IP address of the server that hosts the external MariaDB database to the VPC security group for the MariaDB DB instance. For more information on modifying a VPC security group, go to [Security groups for your VPC](#) in the *Amazon Virtual Private Cloud User Guide*.

The IP address can change when the following conditions are met:

- You are using a public IP address for communication between the external source instance and the DB instance.
- The external source instance was stopped and restarted.

If these conditions are met, verify the IP address before adding it.

You might also need to configure your local network to permit connections from the IP address of your MariaDB DB instance, so that it can communicate with your external MariaDB instance. To find the IP address of the MariaDB DB instance, use the host command.

```
host <RDS_MariaDB_DB_host_name>
```

The host name is the DNS name from the MariaDB DB instance endpoint.

6. Using the client of your choice, connect to the external MariaDB instance and create a MariaDB user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY '<password>;
```

7. For the external MariaDB instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. For example, to grant the REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.*  
TO 'repl_user'@'mydomain.com'  
IDENTIFIED BY '<password>;
```

8. Make the MariaDB DB instance the replica. Connect to the MariaDB DB instance as the master user and identify the external MariaDB database as the replication source instance by using the [mysql.rds_set_external_master_gtid \(p. 626\)](#) command. Use the GTID that you determined in Step 2. The following is an example.

```
CALL mysql.rds_set_external_master_gtid ('mymasterserver.mydomain.com', 3306,  
'repl_user', '<password>', '<GTID>', 0);
```

9. On the MariaDB DB instance, issue the [mysql.rds_start_replication \(p. 964\)](#) command to start replication.

```
CALL mysql.rds_start_replication;
```

Importing data into a MariaDB DB instance

Following, you can find information about methods to import your MariaDB data to an Amazon RDS DB instance running MariaDB.

To do an initial data import into a MariaDB DB instance, you can use the procedures documented in [Restoring a backup into a MySQL DB instance \(p. 871\)](#), as follows:

- To move data from a MySQL DB instance, a MariaDB or MySQL instance in Amazon Elastic Compute Cloud (Amazon EC2) in the same VPC as your MariaDB DB instance, or a small on-premises instance of MariaDB or MySQL, you can use the procedure documented in [Importing data from a MySQL or MariaDB DB to a MySQL or MariaDB DB instance \(p. 879\)](#).
- To move data from a large or production on-premises instance of MariaDB or MySQL, you can use the procedure documented in [Importing data to an Amazon RDS MySQL or MariaDB DB instance with reduced downtime \(p. 881\)](#).
- To move data from an instance of MariaDB or MySQL that is in EC2 in a different VPC than your MariaDB DB instance, or to move data from any data source that can output delimited text files, you can use the procedure documented in [Importing data from any source to a MySQL or MariaDB DB instance \(p. 894\)](#).

You can also use AWS Database Migration Service (AWS DMS) to import data into an Amazon RDS DB instance. AWS DMS can migrate databases without downtime and, for many database engines, continue ongoing replication until you are ready to switch over to the target database. You can migrate to MariaDB from either the same database engine or a different database engine using AWS DMS. If you are migrating from a different database engine, you can use the AWS Schema Conversion Tool to migrate schema objects that are not migrated by AWS DMS. For more information about AWS DMS, see [What is AWS Database Migration Service](#).

You can configure replication into a MariaDB DB instance using MariaDB global transaction identifiers (GTIDs) when the external instance is MariaDB version 10.0.24 or greater, or using binary log coordinates for MySQL instances or MariaDB instances on earlier versions than 10.0.24. Note that MariaDB GTIDs are implemented differently than MySQL GTIDs, which are not supported by Amazon RDS.

To configure replication into a MariaDB DB instance, you can use the following procedures:

- To configure replication into a MariaDB DB instance from an external MySQL instance or an external MariaDB instance running a version prior to 10.0.24, you can use the procedure documented in [Replication with a MySQL or MariaDB instance running external to Amazon RDS \(p. 914\)](#).
- To configure replication into a MariaDB DB instance from an external MariaDB instance running version 10.0.24 or greater, you can use the procedure documented in [Configuring GTID-based replication into a MariaDB DB instance \(p. 613\)](#).

Note

The mysql system database contains authentication and authorization information required to log into your DB instance and access your data. Dropping, altering, renaming, or truncating tables, data, or other contents of the mysql database in your DB instance can result in errors and might render the DB instance and your data inaccessible. If this occurs, the DB instance can be restored from a snapshot using the AWS CLI `restore-db-instance-from-db-snapshot` or recovered using `restore-db-instance-to-point-in-time` commands.

Options for MariaDB database engine

This appendix describes options, or additional features, that are available for Amazon RDS instances running the MariaDB DB engine. To enable these options, you add them to a custom option group, and

then associate the option group with your DB instance. For more information about working with option groups, see [Working with option groups \(p. 212\)](#).

Amazon RDS supports the following options for MariaDB:

Option ID	Engine versions
MARIADB_AUDIT_PLUGIN	MariaDB 10.0.24 and later

MariaDB Audit Plugin support

Amazon RDS supports using the MariaDB Audit Plugin on MariaDB database instances. The MariaDB Audit Plugin records database activity such as users logging on to the database, queries run against the database, and more. The record of database activity is stored in a log file.

Audit Plugin option settings

Amazon RDS supports the following settings for the MariaDB Audit Plugin option.

Option setting	Valid values	Default value	Description
			<ul style="list-style-type: none"> • <code>QUERY_DCL</code>: Similar to the <code>QUERY</code> event, but returns only data control language (DCL) queries (<code>GRANT</code>, <code>REVOKE</code>, and so on).
<code>SERVER_AUDIT_INCL_USERS</code>	Multiple users comma-separated values	None	Include only activity from the specified users. By default, activity is recorded for all users. If a user is specified in both <code>SERVER_AUDIT_EXCL_USERS</code> and <code>SERVER_AUDIT_INCL_USERS</code> , then activity is recorded for the user.
<code>SERVER_AUDIT_EXCL_USERS</code>	Multiple users comma-separated values	None	Exclude activity from the specified users. By default, activity is recorded for all users. If a user is specified in both <code>SERVER_AUDIT_EXCL_USERS</code> and <code>SERVER_AUDIT_INCL_USERS</code> , then activity is recorded for the user.
			<p>The <code>rdsadmin</code> user queries the database every second to check the health of the database. Depending on your other settings, this activity can possibly cause the size of your log file to grow very large, very quickly. If you don't need to record this activity, add the <code>rdsadmin</code> user to the <code>SERVER_AUDIT_EXCL_USERS</code> list.</p> <p>Note CONNECT activity is always recorded for all users, even if the user is specified for this option setting.</p>
<code>SERVER_AUDIT_LOGGING</code>	ON	ON	Logging is active. The only valid value is ON. Amazon RDS does not support deactivating logging. If you want to deactivate logging, remove the MariaDB Audit Plugin. For more information, see Removing the MariaDB Audit Plugin (p. 619) .
<code>SERVER_AUDIT_QUERY_LENGTH</code>	0 to 147483647	1024	The limit on the length of the query string in a record.

Adding the MariaDB Audit Plugin

The general process for adding the MariaDB Audit Plugin to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the option to the option group.
3. Associate the option group with the DB instance.

After you add the MariaDB Audit Plugin, you don't need to restart your DB instance. As soon as the option group is active, auditing begins immediately.

To add the MariaDB Audit Plugin

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a custom DB option group. Choose `mariadb` for **Engine**, and choose **10.0** or later for **Major engine version**. For more information, see [Creating an option group \(p. 214\)](#).

2. Add the **MARIADB_AUDIT_PLUGIN** option to the option group, and configure the option settings. For more information about adding options, see [Adding an option to an option group \(p. 216\)](#). For more information about each setting, see [Audit Plugin option settings \(p. 617\)](#).
3. Apply the option group to a new or existing DB instance.
 - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance \(p. 141\)](#).
 - For an existing DB instance, you apply the option group by modifying the DB instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

Viewing and downloading the MariaDB Audit Plugin log

After you enable the MariaDB Audit Plugin, you access the results in the log files the same way you access any other text-based log files. The audit log files are located at `/rdsdbdata/log/audit/`. For information about viewing the log file in the console, see [Viewing and listing database log files \(p. 504\)](#). For information about downloading the log file, see [Downloading a database log file \(p. 504\)](#).

Modifying MariaDB Audit Plugin settings

After you enable the MariaDB Audit Plugin, you can modify settings for the plugin. For more information about how to modify option settings, see [Modifying an option setting \(p. 221\)](#). For more information about each setting, see [Audit Plugin option settings \(p. 617\)](#).

Removing the MariaDB Audit Plugin

Amazon RDS doesn't support turning off logging in the MariaDB Audit Plugin. However, you can remove the plugin from a DB instance. When you remove the MariaDB Audit Plugin, the DB instance is restarted automatically to stop auditing.

To remove the MariaDB Audit Plugin from a DB instance, do one of the following:

- Remove the MariaDB Audit Plugin option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group \(p. 224\)](#).
- Modify the DB instance and specify a different option group that doesn't include the plugin. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

Parameters for MariaDB

By default, a MariaDB DB instance uses a DB parameter group that is specific to a MariaDB database. This parameter group contains some but not all of the parameters contained in the Amazon RDS DB parameter groups for the MySQL database engine. It also contains a number of new, MariaDB-specific parameters. For information about working with parameter groups and setting parameters, see [Working with DB parameter groups \(p. 228\)](#).

The following MySQL parameters are not available in MariaDB-specific DB parameter groups:

- bind_address
- binlog_error_action
- binlog_gtid_simple_recovery
- binlog_max_flush_queue_time
- binlog_order_commits
- binlog_row_image
- binlog_rows_query_log_events
- binlogging_impossible_mode
- block_encryption_mode
- core_file
- default_tmp_storage_engine
- div_precision_increment
- end_markers_in_json
- enforce_gtid_consistency
- eq_range_index_dive_limit
- explicit_defaults_for_timestamp
- gtid_executed
- gtid-mode
- gtid_next
- gtid_owned
- gtid_purged
- log_bin_basename
- log_bin_index
- log_bin_use_v1_row_events
- log_slow_admin_statements
- log_slow_slave_statements
- log_throttle_queries_not_using_indexes
- master-info-repository
- optimizer_trace
- optimizer_trace_features
- optimizer_trace_limit
- optimizer_trace_max_mem_size
- optimizer_trace_offset
- relay_log_info_repository
- rpl_stop_slave_timeout
- slave_parallel_workers
- slave_pending_jobs_size_max

- slave_rows_search_algorithms
- storage_engine
- table_open_cache_instances
- timed_mutexes
- transaction_allow_batching
- validate-password
- validate_password_dictionary_file
- validate_password_length
- validate_password_mixed_case_count
- validate_password_number_count
- validate_password_policy
- validate_password_special_char_count

For more information on MySQL parameters, go to the [MySQL documentation](#).

The MariaDB-specific DB parameter groups also contain the following parameters that are applicable to MariaDB only. Acceptable ranges for the modifiable parameters are the same as specified in the MariaDB documentation except where noted. RDS for MariaDB parameters are set to the default values of the storage engine you have selected.

- aria_block_size
- aria_checkpoint_interval
- aria_checkpoint_log_activity
- aria_force_start_after_recovery_failures
- aria_group_commit
- aria_group_commit_interval
- aria_log_dir_path
- aria_log_file_size
- aria_log_purge_type
- aria_max_sort_file_size
- aria_page_checksum
- aria_pagecache_age_threshold
- aria_pagecache_division_limit
- aria_recover

RDS for MariaDB supports the values of NORMAL, OFF, and QUICK, but not FORCE or BACKUP.

- aria_repair_threads
- aria_sort_buffer_size
- aria_stats_method
- aria_sync_log_dir
- binlog_annotation_row_events
- binlog_commit_wait_count
- binlog_commit_wait_usec
- binlog_row_image (MariaDB version 10.1 and later)
- deadlock_search_depth_long
- deadlock_search_depth_short
- deadlock_timeout_long
- deadlock_timeout_short

- `explicit_defaults_for_timestamp` (MariaDB version 10.1 and later)
- `extra_max_connections`
- `extra_port`
- `feedback`
- `feedback_send_retry_wait`
- `feedback_send_timeout`
- `feedback_url`
- `feedback_user_info`
- `gtid_domain_id`
- `gtid_strict_mode`
- `histogram_size`
- `histogram_type`
- `innodb_adaptive_hash_index_partitions`
- `innodb_background_scrub_data_check_interval` (MariaDB version 10.1 and later)
- `innodb_background_scrub_data_compressed` (MariaDB version 10.1 and later)
- `innodb_background_scrub_data_interval` (MariaDB version 10.1 and later)
- `innodb_background_scrub_data_uncompressed` (MariaDB version 10.1 and later)
- `innodb_buf_dump_status_frequency` (MariaDB version 10.1 and later)
- `innodb_buffer_pool_populate`
- `innodb_cleaner_lsn_age_factor`
- `innodb_compression_algorithm` (MariaDB version 10.1 and later)
- `innodb_corrupt_table_action`
- `innodb_defragment` (MariaDB version 10.1 and later)
- `innodb_defragment_fill_factor` (MariaDB version 10.1 and later)
- `innodb_defragment_fill_factor_n_recs` (MariaDB version 10.1 and later)
- `innodb_defragment_frequency` (MariaDB version 10.1 and later)
- `innodb_defragment_n_pages` (MariaDB version 10.1 and later)
- `innodb_defragment_stats_accuracy` (MariaDB version 10.1 and later)
- `innodb_empty_free_List_algorithm`
- `innodb_fake_changes`
- `innodb_fatal_semaphore_wait_threshold` (MariaDB version 10.1 and later)
- `innodb_foreground_preflush`
- `innodb_idle_flush_pct` (MariaDB version 10.1 and later)
- `innodb_immediate_scrub_data_uncompressed` (MariaDB version 10.1 and later)
- `innodb_instrument_semaphores` (MariaDB version 10.1 and later)
- `innodb_locking_fake_changes`
- `innodb_log_arch_dir`
- `innodb_log_arch_expire_sec`
- `innodb_log_archive`
- `innodb_log_block_size`
- `innodb_log_checksum_algorithm`
- `innodb_max_bitmap_file_size`
- `innodb_max_changed_pages`
- `innodb_prefix_index_cluster_optimization` (MariaDB version 10.1 and later)
- `innodb_sched_priority_cleaner`
- `innodb_scrub_log` (MariaDB version 10.1 and later)

For more information on MariaDB parameters, go to the [MariaDB documentation](#).

MariaDB on Amazon RDS SQL reference

This appendix describes system stored procedures that are available for Amazon RDS instances running the MariaDB DB engine.

You can use the system stored procedures that are available for MySQL DB instances and MariaDB DB instances. These stored procedures are documented at [MySQL on Amazon RDS SQL reference \(p. 952\)](#). MariaDB DB instances support all of the stored procedures, except for `mysql.rds_set_source_delay`.

Additionally, the following system stored procedures are supported only for Amazon RDS DB instances running MariaDB:

- [mysql.rds_replica_status \(p. 625\)](#)
- [mysql.rds_set_external_master_gtid \(p. 626\)](#)
- [mysql.rds_kill_query_id \(p. 628\)](#)

[mysql.rds_replica_status](#)

Shows the replication status of a MariaDB read replica.

Call this procedure on the read replica to show status information on essential parameters of the replica threads.

Syntax

```
CALL mysql.rds_replica_status;
```

Usage notes

This procedure is only supported for MariaDB DB instances running MariaDB version 10.5 and higher.

This procedure is the equivalent of the `SHOW SLAVE STATUS` command. This command isn't supported for MariaDB version 10.5 and higher DB instances.

In prior versions of MariaDB, this command required the `REPLICATION SLAVE` privilege. In MariaDB version 10.5, it requires the `REPLICATION SLAVE ADMIN` privilege. To protect the RDS management of MariaDB 10.5 DB instances, this new privilege isn't granted to the RDS master user.

Examples

The following example shows the status of a MariaDB read replica:

```
call mysql.rds_replica_status;
```

The response is similar to the following:

```
***** 1. row *****
Slave_IO_State: Waiting for master to send event
Master_Host: XX.XX.XX.XXX
Master_User: rdsrepladmin
Master_Port: 3306
```

```

        Connect_Retry: 60
        Master_Log_File: mysql-bin-changelog.003988
        Read_Master_Log_Pos: 405
            Relay_Log_File: relaylog.011024

        Slave_Transactional_Groups: 3658
1 row in set (0.000 sec)

Query OK, 0 rows affected (0.000 sec)

```

[mysql.rds_set_external_master_gtid](#)

Configures GTID-based replication from a MariaDB instance running external to Amazon RDS to a MariaDB DB instance. This stored procedure is supported only where the external MariaDB instance is version 10.0.24 or greater. When setting up replication where one or both instances do not support MariaDB global transaction identifiers (GTIDs), use [mysql.rds_set_external_master \(p. 954\)](#).

Using GTIDs for replication provides crash-safety features not offered by binary log replication, so we recommend it in cases where the replicating instances support it.

Syntax

```
CALL mysql.rds_set_external_master_gtid(
    host_name
    , host_port
    , replication_user_name
    , replication_user_password
    , gtid
    , ssl_encryption
);
```

Parameters

host_name

String. The host name or IP address of the MariaDB instance running external to Amazon RDS that will become the source instance.

host_port

Integer. The port used by the MariaDB instance running external to Amazon RDS to be configured as the source instance. If your network configuration includes SSH port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

String. The ID of a user with REPLICATION SLAVE permissions in the MariaDB DB instance to be configured as the read replica.

replication_user_password

String. The password of the user ID specified in *replication_user_name*.

gtid

String. The global transaction ID on the source instance that replication should start from.

You can use @@gtid_current_pos to get the current GTID if the source instance has been locked while you are configuring replication, so the binary log doesn't change between the points when you get the GTID and when replication starts.

Otherwise, if you are using mysqldump version 10.0.13 or greater to populate the replica instance prior to starting replication, you can get the GTID position in the output by using the --master-data or --dump-slave options. If you are not using mysqldump version 10.0.13 or greater, you can run the SHOW MASTER STATUS or use those same mysqldump options to get the binary log file name and position, then convert them to a GTID by running BINLOG_GTID_POS on the external MariaDB instance:

```
SELECT BINLOG_GTID_POS('<binary log file name>', <binary log file position>);
```

For more information about the MariaDB implementation of GTIDs, go to [Global transaction ID](#) in the MariaDB documentation.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

Note

The MASTER_SSL_VERIFY_SERVER_CERT option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

Usage notes

The `mysql.rds_set_external_master_gtid` procedure must be run by the master user. It must be run on the MariaDB DB instance that you are configuring as the replica of a MariaDB instance running external to Amazon RDS. Before running `mysql.rds_set_external_master_gtid`, you must have configured the instance of MariaDB running external to Amazon RDS as a source instance. For more information, see [Importing data into a MariaDB DB instance \(p. 616\)](#).

Warning

Do not use `mysql.rds_set_external_master_gtid` to manage replication between two Amazon RDS DB instances. Use it only when replicating with a MariaDB instance running external to RDS. For information about managing replication between Amazon RDS DB instances, see [Working with read replicas \(p. 278\)](#).

After calling `mysql.rds_set_external_master_gtid` to configure an Amazon RDS DB instance as a read replica, you can call [mysql.rds_start_replication \(p. 964\)](#) on the replica to start the replication process. You can call [mysql.rds_reset_external_master \(p. 961\)](#) to remove the read replica configuration.

When `mysql.rds_set_external_master_gtid` is called, Amazon RDS records the time, user, and an action of "set master" in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

Examples

When run on a MariaDB DB instance, the following example configures it as the replica of an instance of MariaDB running external to Amazon RDS.

```
call mysql.rds_set_external_master_gtid
('Sourcedb.some.com',3306,'ReplicationUser','SomePassWOrd','0-123-456',0);
```

mysql.rds_kill_query_id

Ends a query running against the MariaDB server.

Syntax

```
CALL mysql.rds_kill_query_id(queryID);
```

Parameters

queryID

Integer. The identity of the query to be ended.

Usage notes

To stop a query running against the MariaDB server, use the `mysql.rds_kill_query_id` procedure and pass in the ID of that query. To obtain the query ID, query the MariaDB [Information schema PROCESSLIST table](#), as shown following:

```
SELECT USER, HOST, COMMAND, TIME, STATE, INFO, QUERY_ID FROM
INFORMATION_SCHEMA.PROCESSLIST WHERE USER = '<user name>';
```

The connection to the MariaDB server is retained.

Examples

The following example ends a query with a query ID of 230040:

```
call mysql.rds_kill_query_id(230040);
```

Microsoft SQL Server on Amazon RDS

Amazon RDS supports DB instances running several versions and editions of Microsoft SQL Server. Following, you can find the most recent supported version of each major version. For the full list of supported versions, editions, and RDS engine versions, see [Microsoft SQL Server versions on Amazon RDS \(p. 637\)](#).

- SQL Server 2019 CU8 15.00.4073.23, released per [KB4577194](#) on October 1, 2020.
- SQL Server 2017 CU22 14.00.3356.20, released per [KB4577467](#) on September 10, 2020.
- SQL Server 2016 SP2 CU15 13.00.5850.14, released per [KB4577775](#) on September 28, 2020.
- SQL Server 2014 SP3 CU4 12.00.6329.1, released per [KB4500181](#) on July 29, 2019.
- SQL Server 2012 SP4 GDR 11.0.7493.4, released per [KB4532098](#) on February 11, 2020.
- SQL Server 2008: It's no longer possible to provision new instances in any Region. Amazon RDS is actively migrating existing instances off this version.

For information about licensing for SQL Server, see [Licensing Microsoft SQL Server on Amazon RDS \(p. 655\)](#). For information about SQL Server builds, see this Microsoft support article about [the latest SQL Server builds](#).

With Amazon RDS, you can create DB instances and DB snapshots, point-in-time restores, and automated or manual backups. DB instances running SQL Server can be used inside a VPC. You can also use Secure Sockets Layer (SSL) to connect to a DB instance running SQL Server, and you can use transparent data encryption (TDE) to encrypt data at rest. Amazon RDS currently supports Multi-AZ deployments for SQL Server using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs) as a high-availability, failover solution.

To deliver a managed service experience, Amazon RDS does not provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application such as Microsoft SQL Server Management Studio. Amazon RDS does not allow direct host access to a DB instance via Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection. When you create a DB instance, the master user is assigned to the `db_owner` role for all user databases on that instance, and has all database-level permissions except for those that are used for backups. Amazon RDS manages backups for you.

Before creating your first DB instance, you should complete the steps in the setting up section of this guide. For more information, see [Setting up for Amazon RDS \(p. 67\)](#).

Common management tasks for Microsoft SQL Server on Amazon RDS

The following are the common management tasks you perform with an Amazon RDS for SQL Server DB instance, with links to relevant documentation for each task.

Task area	Relevant documentation
Instance classes, storage, and PIOPS If you are creating a DB instance for production purposes, you should understand how instance classes, storage types, and Provisioned IOPS work in Amazon RDS.	DB instance class support for Microsoft SQL Server (p. 634) Amazon RDS storage types (p. 40)
Multi-AZ deployments A production DB instance should use Multi-AZ deployments. Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances. Multi-AZ deployments for SQL Server are implemented using SQL Server's native DBM or AGs technology.	High availability (Multi-AZ) for Amazon RDS (p. 53) Multi-AZ deployments using Microsoft SQL Server Database Mirroring or Always On availability groups (p. 643)
Amazon Virtual Private Cloud (VPC) If your AWS account has a default VPC, then your DB instance is automatically created inside the default VPC. If your account does not have a default VPC, and you want the DB instance in a VPC, you must create the VPC and subnet groups before you create the DB instance.	Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1718) Working with a DB instance in a VPC (p. 1727)
Security groups By default, DB instances are created with a firewall that prevents access to them. You therefore must create a security group with the correct IP addresses and network configuration to access the DB instance. The security group you create depends on what Amazon EC2 platform your DB instance is on, and whether you will access your DB instance from an Amazon EC2 instance. In general, if your DB instance is on the <i>EC2-Classic</i> platform, you will need to create a DB security group; if your DB instance is on the <i>EC2-VPC</i> platform, you will need to create a VPC security group.	Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1718) Controlling access with security groups (p. 1699)
Parameter groups If your DB instance is going to require specific database parameters, you should create a parameter group before you create the DB instance.	Working with DB parameter groups (p. 228)
Option groups If your DB instance is going to require specific database options, you should create an option group before you create the DB instance.	Options for the Microsoft SQL Server database engine (p. 749)
Connecting to your DB instance After creating a security group and associating it to a DB instance, you can connect to the DB instance using any standard SQL client application such as Microsoft SQL Server Management Studio.	Connecting to a DB instance running the Microsoft SQL Server database engine (p. 656)
Backup and restore	Working with backups (p. 328) Importing and exporting SQL Server databases (p. 671)

Task area	Relevant documentation
When you create your DB instance, you can configure it to take automated backups. You can also back up and restore your databases manually by using full backup files (.bak files).	
Monitoring You can monitor your SQL Server DB instance by using CloudWatch Amazon RDS metrics, events, and enhanced monitoring.	Viewing DB instance metrics (p. 548) Viewing Amazon RDS events (p. 503)
Log files You can access the log files for your SQL Server DB instance.	Accessing Amazon RDS database log files (p. 504) Microsoft SQL Server database log files (p. 516)

There are also advanced administrative tasks for working with SQL Server DB instances. For more information, see the following documentation:

- [Common DBA tasks for Microsoft SQL Server \(p. 809\)](#).
- [Using Windows Authentication with a SQL Server DB instance \(p. 711\)](#)
- [Accessing the tempdb database \(p. 810\)](#)

Limits for Microsoft SQL Server DB instances

The Amazon RDS implementation of Microsoft SQL Server on a DB instance has some limitations that you should be aware of:

- The maximum number of databases supported on a DB instance depends on the instance class type and the availability mode—Single-AZ, Multi-AZ Database Mirroring (DBM), or Multi-AZ Availability Groups (AGs). The Microsoft SQL Server system databases don't count toward this limit.

The following table shows the maximum number of supported databases for each instance class type and availability mode. Use this table to help you decide if you can move from one instance class type to another, or from one availability mode to another. If your source DB instance has more databases than the target instance class type or availability mode can support, modifying the DB instance fails. You can see the status of your request in the **Events** pane.

Instance class type	Single-AZ	Multi-AZ with DBM	Multi-AZ with Always On AGs
db.*.micro to db.*.medium	30	N/A	N/A
db.*.large	30	30	30
db.*.xlarge to db.*.16xlarge	100	50	75
db.*.24xlarge	100	50	100

* Represents the different instance class types.

For example, let's say that your DB instance runs on a db.*.16xlarge with Single-AZ and that it has 76 databases. You modify the DB instance to upgrade to using Multi-AZ Always On AGs. This upgrade fails, because your DB instance contains more databases than your target configuration can support. If you upgrade your instance class type to db.*.24xlarge instead, the modification succeeds.

If the upgrade fails, you see events and messages similar to the following:

- Unable to modify database instance class. The instance has 76 databases, but after conversion it would only support 75.
- Unable to convert the DB instance to Multi-AZ: The instance has 76 databases, but after conversion it would only support 75.

If the point-in-time restore or snapshot restore fails, you see events and messages similar to the following:

- Database instance put into incompatible-restore. The instance has 76 databases, but after conversion it would only support 75.
- Some ports are reserved for Amazon RDS, and you can't use them when you create a DB instance.
- Client connections from IP addresses within the range 169.254.0.0/16 are not permitted. This is the Automatic Private IP Addressing Range (APIPA), which is used for local-link addressing.
- SQL Server Standard Edition uses only a subset of the available processors if the DB instance has more processors than the software limits (24 cores, 4 sockets, and 128GB RAM). Examples of this are the db.m5.24xlarge and db.r5.24xlarge instance classes.

For more information, see the table of scale limits under [Editions and supported features of SQL Server 2019 \(15.x\)](#) in the Microsoft documentation.

- Amazon RDS for SQL Server doesn't support importing data into the msdb database.
- You can't rename databases on a DB instance in a SQL Server Multi-AZ deployment.
- Make sure that you use these guidelines when setting the following DB parameters on RDS for SQL Server:
 - `max server memory (mb) >= 256 MB`
 - `max worker threads >= (number of logical CPUs * 7)`
 - For the upper limit on `max worker threads`, see [Configure the max worker threads server configuration option](#) in the Microsoft documentation.

For more information on setting DB parameters, see [Working with DB parameter groups \(p. 228\)](#).

- The maximum storage size for SQL Server DB instances is the following:
 - General Purpose (SSD) storage – 16 TiB for all editions
 - Provisioned IOPS storage – 16 TiB for all editions
 - Magnetic storage – 1 TiB for all editions

If you have a scenario that requires a larger amount of storage, you can use sharding across multiple DB instances to get around the limit. This approach requires data-dependent routing logic in applications that connect to the sharded system. You can use an existing sharding framework, or you can write custom code to enable sharding. If you use an existing framework, the framework can't install any components on the same server as the DB instance.

- The minimum storage size for SQL Server DB instances is the following:
 - General Purpose (SSD) storage – 20 GiB for Enterprise, Standard, Web, and Express Editions
 - Provisioned IOPS storage – 20 GiB for Enterprise, Standard, Web, and Express Editions
 - Magnetic storage – 20 GiB for Enterprise, Standard, Web, and Express Editions
- Amazon RDS doesn't support running these services on the same server as your RDS DB instance:
 - Data Quality Services
 - Master Data Services

To use these features, we recommend that you install SQL Server on an Amazon EC2 instance, or use an on-premises SQL Server instance. In these cases, the EC2 or SQL Server instance acts as the Master Data Services server for your SQL Server DB instance on Amazon RDS. You can install SQL Server on an Amazon EC2 instance with Amazon EBS storage, pursuant to Microsoft licensing policies.

- Because of limitations in Microsoft SQL Server, restoring to a point in time before successfully running `DROP DATABASE` might not reflect the state of that database at that point in time. For example, the dropped database is typically restored to its state up to 5 minutes before the `DROP DATABASE` command was issued. This type of restore means that you can't restore the transactions made during those few minutes on your dropped database. To work around this, you can reissue the `DROP DATABASE` command after the restore operation is completed. Dropping a database removes the transaction logs for that database.
 - For SQL Server, you create your databases after you create your DB instance. Database names follow the usual SQL Server naming rules with the following differences:
 - Database names can't start with `rdsadmin`.
 - They can't start or end with a space or a tab.
 - They can't contain any of the characters that create a new line.
 - They can't contain a single quote (`'`).

DB instance class support for Microsoft SQL Server

The computation and memory capacity of a DB instance is determined by its DB instance class. The DB instance class you need depends on your processing power and memory requirements. For more information, see [DB instance classes \(p. 7\)](#).

The following list of DB instance classes supported for Microsoft SQL Server is provided here for your convenience. For the most current list, see the RDS console: <https://console.aws.amazon.com/rds/>.

SQL Server edition	2019 support range	2017 and 2016 support range	2014 and 2012 support range
Enterprise Edition	db.t3.xlarge-db.t3.2xlarge db.r5.xlarge-db.r5.24xlarge db.r5b.xlarge-db.r5b.24xlarge db.r5d.xlarge-db.r5d.24xlarge db.m5.xlarge-db.m5.24xlarge db.m5d.xlarge-db.m5d.24xlarge db.x1.16xlarge-db.x1.32xlarge db.xle.xlarge-db.xle.32xlarge db.z1d.xlarge-db.z1d.12xlarge	db.t3.xlarge-db.t3.2xlarge db.r3.xlarge-db.r3.8xlarge db.r4.16xlarge-db.r4.8xlarge db.r5.24xlarge-db.r5.24xlarge db.r5b.24xlarge-db.r5b.24xlarge db.r5d.24xlarge-db.r5d.24xlarge db.m4.16xlarge-db.m4.10xlarge db.m5.24xlarge-db.m5.24xlarge db.x1.32xlarge-db.x1.16xlarge db.xle.32xlarge-db.xle.16xlarge db.z1d.12xlarge-db.z1d.xlarge	db.t3.xlarge-db.t3.2xlarge db.r3.xlarge-db.r3.8xlarge db.r4.16xlarge-db.r4.8xlarge db.r5.24xlarge-db.r5.24xlarge db.r5b.24xlarge-db.r5b.24xlarge db.r5d.24xlarge-db.r5d.24xlarge db.m4.16xlarge-db.m4.10xlarge db.m5.24xlarge-db.m5.24xlarge db.x1.32xlarge-db.x1.16xlarge db.xle.32xlarge-db.xle.16xlarge db.z1d.12xlarge-db.z1d.xlarge

Microsoft SQL Server security

The Microsoft SQL Server database engine uses role-based security. The master user name you use when you create a DB instance is a SQL Server Authentication login that is a member of the `processadmin`, `public`, and `setupadmin` fixed server roles.

Any user who creates a database is assigned to the db_owner role for that database and has all database-level permissions except for those that are used for backups. Amazon RDS manages backups for you.

The following server-level roles are not currently available in Amazon RDS:

- bulkadmin
- dbcreator
- diskadmin
- securityadmin
- serveradmin
- sysadmin

The following server-level permissions are not available on SQL Server DB instances:

- ALTER ANY CREDENTIAL
- ALTER ANY EVENT NOTIFICATION
- ALTER ANY EVENT SESSION
- ALTER RESOURCES
- ALTER SETTINGS (you can use the DB parameter group API operations to modify parameters; for more information, see [Working with DB parameter groups \(p. 228\)](#))
- AUTHENTICATE SERVER
- CONTROL_SERVER
- CREATE DDL EVENT NOTIFICATION
- CREATE ENDPOINT
- CREATE TRACE EVENT NOTIFICATION
- EXTERNAL ACCESS ASSEMBLY
- SHUTDOWN (You can use the RDS reboot option instead)
- UNSAFE ASSEMBLY
- ALTER ANY AVAILABILITY GROUP (SQL Server 2012 only)
- CREATE ANY AVAILABILITY GROUP (SQL Server 2012 only)

Compliance program support for Microsoft SQL Server DB instances

AWS Services in scope have been fully assessed by a third-party auditor and result in a certification, attestation of compliance, or Authority to Operate (ATO). For more information, see [AWS services in scope by compliance program](#).

HIPAA support for Microsoft SQL Server DB instances

You can use Amazon RDS for Microsoft SQL Server databases to build HIPAA-compliant applications. You can store healthcare-related information, including protected health information (PHI), under a Business Associate Agreement (BAA) with AWS. For more information, see [HIPAA compliance](#).

Amazon RDS for SQL Server supports HIPAA for the following versions and editions:

- SQL Server 2019 Enterprise, Standard, and Web Editions

- SQL Server 2017 Enterprise, Standard, and Web Editions
- SQL Server 2016 Enterprise, Standard, and Web Editions
- SQL Server 2014 Enterprise, Standard, and Web Editions
- SQL Server 2012 Enterprise, Standard, and Web Editions

To enable HIPAA support on your DB instance, set up the following three components.

Component	Details
Auditing	To set up auditing, set the parameter <code>rds.sqlserver_audit</code> to the value <code>fedramp_hipaa</code> . If your DB instance is not already using a custom DB parameter group, you must create a custom parameter group and attach it to your DB instance before you can modify the <code>rds.sqlserver_audit</code> parameter. For more information, see Working with DB parameter groups (p. 228) .
Transport encryption	To set up transport encryption, force all connections to your DB instance to use Secure Sockets Layer (SSL). For more information, see Forcing connections to your DB instance to use SSL (p. 704) .
Encryption at rest	To set up encryption at rest, you have two options: <ol style="list-style-type: none"> 1. If you're running SQL Server 2012–2019 Enterprise Edition or 2019 Standard Edition, you can use Transparent Data Encryption (TDE) to achieve encryption at rest. For more information, see Support for Transparent Data Encryption in SQL Server (p. 754). 2. You can set up encryption at rest by using AWS Key Management Service (AWS KMS) encryption keys. For more information, see Encrypting Amazon RDS resources (p. 1630).

SSL support for Microsoft SQL Server DB instances

You can use SSL to encrypt connections between your applications and your Amazon RDS DB instances running Microsoft SQL Server. You can also force all connections to your DB instance to use SSL. If you force connections to use SSL, it happens transparently to the client, and the client doesn't have to do any work to use SSL.

SSL is supported in all AWS Regions and for all supported SQL Server editions. For more information, see [Using SSL with a Microsoft SQL Server DB instance \(p. 704\)](#).

Microsoft SQL Server versions on Amazon RDS

You can specify any currently supported Microsoft SQL Server version when creating a new DB instance. You can specify the Microsoft SQL Server major version (such as Microsoft SQL Server 14.00), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified.

The following table shows the supported versions for all editions and all AWS Regions, except where noted. You can also use the `describe-db-engine-versions` AWS CLI command to see a list of supported versions, as well as defaults for newly created DB instances.

SQL Server versions supported in RDS

Major version	Minor version	RDS API EngineVersion and CLI engine-version
SQL Server 2019	15.00.4073.23 (CU8)	15.00.4073.23.v1
	15.00.4043.16 (CU5)	15.00.4043.16.v1
SQL Server 2017	14.00.3356.20 (CU22)	14.00.3356.20.v1
	14.00.3294.2 (CU20)	14.00.3294.2.v1
	14.00.3281.6 (CU19)	14.00.3281.6.v1
	14.00.3223.3 (CU16)	14.00.3223.3.v1
	14.00.3192.2 (CU15 GDR)	14.00.3192.2.v1
	14.00.3049.1 (CU13 hotfix update)	14.00.3049.1.v1
	14.00.3035.2 (CU9 GDR)	14.00.3035.2.v1
	14.00.3015.40 (CU3)	14.00.3015.40.v1
	14.00.1000.169 (RTM)	14.00.1000.169.v1
SQL Server 2016	13.00.5850.14 (SP2 CU15)	13.00.5850.14.v1
	13.00.5820.21 (SP2 CU13)	13.00.5820.21.v1
	13.00.5598.27 (SP2 CU11)	13.00.5598.27.v1
	13.00.5426.0 (SP2 CU8)	13.00.5426.0.v1
	13.00.5366.0 (SP2)	13.00.5366.0.v1
	13.00.5292.0 (CU6)	13.00.5292.0.v1
	13.00.5216.0 (CU3)	13.00.5216.0.v1
	13.00.4522.0 (SP1 CU10 security update)	13.00.4522.0.v1
	13.00.4466.4 (SP1 CU7)	13.00.4466.4.v1
	13.00.4451.0 (SP1 CU5)	13.00.4451.0.v1
	13.00.4422.0 (SP1 CU2)	13.00.4422.0.v1
	13.00.2164.0 (RTM CU2)	13.00.2164.0.v1
SQL Server 2014	12.00.6329.1 (SP3 CU4)	12.00.6329.1.v1
	12.00.6293.0 (SP3 CU3)	12.00.6293.0.v1
	12.00.5571.0 (SP2 CU10)	12.00.5571.0.v1
	12.00.5546.0 (SP2 CU5)	12.00.5546.0.v1
	12.00.5000.0 (SP2)	12.00.5000.0.v1

Major version	Minor version	RDS API EngineVersion and CLI engine-version
SQL Server 2012	11.00.7493.4 (SP4 GDR)	11.00.7493.4.v1
	11.00.7462.6 (SP4 GDR)	11.00.7462.6.v1
	11.00.6594.0 (SP3 CU8)	11.00.6594.0.v1
	11.00.6020.0 (SP3)	11.00.6020.0.v1
	11.00.5058.0 (SP2), except US East (Ohio), Canada (Central), and Europe (London)	11.00.5058.0.v1

Version management in Amazon RDS

Amazon RDS includes flexible version management that enables you to control when and how your DB instance is patched or upgraded. This enables you to do the following for your DB engine:

- Maintain compatibility with database engine patch versions.
- Test new patch versions to verify that they work with your application before you deploy them in production.
- Plan and perform version upgrades to meet your service level agreements and timing requirements.

Microsoft SQL Server engine patching in Amazon RDS

Amazon RDS periodically aggregates official Microsoft SQL Server database patches into a DB instance engine version that's specific to Amazon RDS. For more information about the Microsoft SQL Server patches in each engine version, see [Version and feature support on Amazon RDS](#).

Currently, you manually perform all engine upgrades on your DB instance. For more information, see [Upgrading the Microsoft SQL Server DB engine \(p. 666\)](#).

Deprecation schedule for major engine versions of Microsoft SQL Server on Amazon RDS

The table following displays the planned schedule of deprecations for major engine versions of Microsoft SQL Server.

Date	Information
July 12, 2019	<p>The Amazon RDS team deprecated support for Microsoft SQL Server 2008 R2 in June 2019. Customers who are migrating to SQL Server 2012 (latest minor version available).</p> <p>To avoid an automatic upgrade from Microsoft SQL Server 2008 R2, you can upgrade at any time. For more information, see Upgrading a DB instance engine version (p. 271).</p>
April 25, 2019	Before the end of April 2019, you will no longer be able to create new Amazon RDS for Microsoft SQL Server 2008R2.

Microsoft SQL Server features on Amazon RDS

The supported SQL Server versions on Amazon RDS include the following features.

Microsoft SQL Server 2019 features

SQL Server 2019 includes many new features, such as the following:

- Accelerated database recovery (ADR) – Reduces crash recovery time after a restart or a long-running transaction rollback.
- Intelligent Query Processing (IQP):
 - Row mode memory grant feedback – Corrects excessive grants automatically, that would otherwise result in wasted memory and reduced concurrency.
 - Batch mode on rowstore – Enables batch mode execution for analytic workloads without requiring columnstore indexes.
 - Table variable deferred compilation – Improves plan quality and overall performance for queries that reference table variables.
- Intelligent performance:
 - `OPTIMIZE_FOR_SEQUENTIAL_KEY` index option – Improves throughput for high-concurrency inserts into indexes.
 - Improved indirect checkpoint scalability – Helps databases with heavy DML workloads.
 - Concurrent Page Free Space (PFS) updates – Enables handling as a shared latch rather than an exclusive latch.
- Monitoring improvements:
 - `WAIT_ON_SYNC_STATISTICS_REFRESH` wait type – Shows accumulated instance-level time spent on synchronous statistics refresh operations.
 - Database-scoped configurations – Include `LIGHTWEIGHT_QUERY_PROFILING` and `LAST_QUERY_PLAN_STATS`.
 - Dynamic management functions (DMFs) – Include `sys.dm_exec_query_plan_stats` and `sys.dm_db_page_info`.
- Verbose truncation warnings – The data truncation error message defaults to include table and column names and the truncated value.
- Resumable online index creation – In SQL Server 2017, only resumable online index rebuild is supported.

For the full list of SQL Server 2019 features, see [What's new in SQL Server 2019 \(15.x\)](#) in the Microsoft documentation.

For a list of unsupported features, see [Features not supported and features with limited support \(p. 643\)](#).

Microsoft SQL Server 2017 features

SQL Server 2017 includes many new features, such as the following:

- Adaptive query processing
- Automatic plan correction
- GraphDB
- Resumable index rebuilds

For the full list of SQL Server 2017 features, see [What's new in SQL Server 2017](#) in the Microsoft documentation.

For a list of unsupported features, see [Features not supported and features with limited support \(p. 643\)](#).

Microsoft SQL Server 2016 features

Amazon RDS supports the following features of SQL Server 2016:

- Always Encrypted
- JSON Support
- Operational Analytics
- Query Store
- Temporal Tables

For the full list of SQL Server 2016 features, see [What's new in SQL Server 2016](#) in the Microsoft documentation.

Microsoft SQL Server 2014 features

In addition to supported features of SQL Server 2012, Amazon RDS supports the new query optimizer available in SQL Server 2014, and also the delayed durability feature.

For a list of unsupported features, see [Features not supported and features with limited support \(p. 643\)](#).

SQL Server 2014 supports all the parameters from SQL Server 2012 and uses the same default values. SQL Server 2014 includes one new parameter, backup checksum default. For more information, see [How to enable the CHECKSUM option if backup utilities do not expose the option](#) in the Microsoft documentation.

Microsoft SQL Server 2012 features

In addition to supported features of SQL Server 2008 R2, Amazon RDS supports the following SQL Server 2012 features:

- Columnstore indexes (Enterprise Edition)
- Online Index Create, Rebuild and Drop for XML, varchar(max), nvarchar(max), and varbinary(max) data types (Enterprise Edition)
- Flexible Server Roles
- Service Broker is supported, Service Broker endpoints are not supported
- Partially Contained Databases
- Sequences
- Transparent Data Encryption (Enterprise Edition only)
- THROW statement
- New and enhanced spatial types
- UTF-16 Support
- ALTER ANY SERVER ROLE server-level permission

For more information about SQL Server 2012, see [Features supported by the editions of SQL Server 2012](#) in the Microsoft documentation.

For a list of unsupported features, see [Features not supported and features with limited support \(p. 643\)](#).

Some SQL Server parameters have changed in SQL Server 2012.

- The following parameters have been removed from SQL Server 2012: `awe_enabled`, `precompute_rank`, and `sql_mail_xps`. These parameters were not modifiable in SQL Server DB Instances and their removal should have no impact on your SQL Server use.
- A new `contained_database_authentication` parameter in SQL Server 2012 supports partially contained databases. When you enable this parameter and then create a partially contained database, an authorized user's user name and password is stored within the partially contained database instead of in the primary database. For more information about partially contained databases, see [Contained databases](#) in the Microsoft documentation.

Microsoft SQL Server 2008 R2 deprecated on Amazon RDS

We are upgrading all existing instances that are still using SQL Server 2008 R2 to the latest minor version of SQL Server 2012. For more information, see [Version management in Amazon RDS \(p. 639\)](#).

For more information about SQL Server 2008 R2, see [Features supported by the editions of SQL Server 2008 R2](#) in the Microsoft documentation.

Change data capture support for Microsoft SQL Server DB instances

Amazon RDS supports change data capture (CDC) for your DB instances running Microsoft SQL Server. CDC captures changes that are made to the data in your tables, and stores metadata about each change that you can access later. For more information, see [Change data capture](#) in the Microsoft documentation.

Amazon RDS supports CDC for the following SQL Server editions and versions:

- Microsoft SQL Server Enterprise Edition (All versions)
- Microsoft SQL Server Standard Edition:
 - 2019
 - 2017
 - 2016 version 13.00.4422.0 SP1 CU2 and later

To use CDC with your Amazon RDS DB instances, first enable or disable CDC at the database level by using RDS-provided stored procedures. After that, any user that has the `db_owner` role for that database can use the native Microsoft stored procedures to control CDC on that database. For more information, see [Using change data capture \(p. 820\)](#).

You can use CDC and AWS Database Migration Service to enable ongoing replication from SQL Server DB instances.

Features not supported and features with limited support

The following Microsoft SQL Server features are not supported on Amazon RDS:

- Backing up to Microsoft Azure Blob Storage
- Buffer pool extension
- Custom password policies
- Data Quality Services
- Database Log Shipping
- Extended stored procedures, including xp_cmdshell
- FILESTREAM support
- File tables
- Machine Learning and R Services (requires OS access to install it)
- Maintenance Plans
- Performance Data Collector
- Policy-Based Management
- PolyBase
- Replication
- Resource Governor
- Server-level triggers
- Service Broker endpoints
- Stretch database
- T-SQL endpoints (all operations using CREATE ENDPOINT are unavailable)
- WCF Data Services

The following Microsoft SQL Server features have limited support on Amazon RDS:

- Distributed Queries / Linked Servers. For more information, see: [Implementing linked servers with Amazon RDS for Microsoft SQL Server](#).

Multi-AZ deployments using Microsoft SQL Server Database Mirroring or Always On availability groups

Amazon RDS supports Multi-AZ deployments for DB instances running Microsoft SQL Server by using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances. In the event of planned database maintenance or unplanned service disruption, Amazon RDS automatically fails over to the up-to-date secondary replica so database operations can resume quickly without manual intervention. The primary and secondary instances use the same endpoint, whose physical network address transitions to the passive secondary replica as part of the failover process. You don't have to reconfigure your application when a failover occurs.

Amazon RDS manages failover by actively monitoring your Multi-AZ deployment and initiating a failover when a problem with your primary occurs. Failover doesn't occur unless the standby and primary are

fully in sync. Amazon RDS actively maintains your Multi-AZ deployment by automatically repairing unhealthy DB instances and re-establishing synchronous replication. You don't have to manage anything. Amazon RDS handles the primary, the witness, and the standby instance for you. When you set up SQL Server Multi-AZ, RDS configures passive secondary instances for all of the databases on the instance.

For more information, see [Multi-AZ deployments for Microsoft SQL Server \(p. 698\)](#).

Using Transparent Data Encryption to encrypt data at rest

Amazon RDS supports Microsoft SQL Server Transparent Data Encryption (TDE), which transparently encrypts stored data. Amazon RDS uses option groups to enable and configure these features. For more information about the TDE option, see [Support for Transparent Data Encryption in SQL Server \(p. 754\)](#).

Functions and stored procedures for Amazon RDS for Microsoft SQL Server

The following table lists Amazon RDS functions and stored procedures that help automate SQL Server tasks.

SQL Server functions and stored procedures

Task type	Procedure or function	Where it's used
Administrative tasks	<code>rds_drop_database</code>	Dropping a Microsoft SQL Server database (p. 818)
	<code>rds_failover</code>	Determining the last failover time (p. 817)
	<code>rds_modify_db</code>	Renaming a Microsoft SQL Server database in a Multi-AZ deployment (p. 818)
	<code>rds_read_error_log</code>	Viewing error and agent logs (p. 824)
	<code>rds_set_configuration</code>	Setting DB instance configurations: <ul style="list-style-type: none">• Change data capture for Multi-AZ instances (p. 821)• Setting the retention period for trace and dump files (p. 824)• Compressing backup files (p. 685)
	<code>rds_set_database</code>	Transitioning a Microsoft SQL Server database from OFFLINE to ONLINE (p. 820)
	<code>rds_show_configuration</code>	Show values set using <code>rds_set_configuration</code> : <ul style="list-style-type: none">• Change data capture for Multi-AZ instances (p. 821)• Setting the retention period for trace and dump files (p. 824)
	<code>rds_shrink_tempdb</code>	Shrinking the tempdb database (p. 810)
Change data capture (CDC)	<code>rds_cdc_disable</code>	Disabling CDC (p. 820)

Task type	Procedure or function	Where it's used
	<code>rds_cdc_enable_db</code>	Enabling CDC (p. 820)
Database Mail	<code>rds_fn_sysmail_viewitem</code>	Viewing messages, logs, and attachments (p. 742)
	<code>rds_fn_sysmail_viewitemlog</code>	Viewing messages, logs, and attachments (p. 742)
	<code>rds_fn_sysmail_viewitemattachment</code>	Viewing item attachments, and attachments (p. 742)
	<code>rds_sysmail_start</code>	Starting and stopping the mail queue: <ul style="list-style-type: none"> Starting the mail queue (p. 743) Stopping the mail queue (p. 743)
	<code>rds_sysmail_delete</code>	Deleting messages (p. 742)
Native backup and restore	<code>rds_backup_database</code>	Backing up a database (p. 675)
	<code>rds_cancel_task</code>	Canceling a task (p. 682)
	<code>rds_finish_restore</code>	Finishing a database restore (p. 681)
	<code>rds_restore_database</code>	Restoring a database (p. 678)
	<code>rds_restore_log</code>	Restoring a log (p. 680)
Amazon S3 file transfer	<code>rds_delete_file</code>	Deleting files on the RDS DB instance (p. 729)
	<code>rds_download_file</code>	Downloading files from an Amazon S3 bucket to a SQL Server DB instance (p. 727)
	<code>rds_gather_file</code>	Gathering files on the RDS DB instance (p. 728)
	<code>rds_upload_to_s3</code>	Uploading files from a SQL Server DB instance to an Amazon S3 bucket (p. 728)
Microsoft Distributed Transaction Coordinator (MSDTC)	<code>rds_msdtc_transaction_tracing</code>	Using transaction tracing (p. 804)
SQL Server Audit	<code>rds_fn_get_audit_file</code>	Viewing audit logs (p. 760)

Task type	Procedure or function	Where it's used
Microsoft Business Intelligence (MSBI)	rds_msbi_task	SQL Server Analysis Services (SSAS): <ul style="list-style-type: none"> Deploying SSAS projects on Amazon RDS (p. 767) Adding a domain user as a database administrator (p. 770) Backing up an SSAS database (p. 770) Restoring an SSAS database (p. 771) SQL Server Integration Services (SSIS): <ul style="list-style-type: none"> Administrative permissions on SSISDB (p. 779) Deploying an SSIS project (p. 781) SQL Server Reporting Services (SSRS): <ul style="list-style-type: none"> Granting access to domain users (p. 792) Revoking system-level permissions (p. 793)
	rds_fn_task_Status	Status of MSBI tasks: <ul style="list-style-type: none"> SSAS: Monitoring the status of a deployment task (p. 768) SSIS: Monitoring the status of a deployment task (p. 781) SSRS: Monitoring the status of a task (p. 793)
SSIS	rds_drop_ssis	Dropping the SSISDB database (p. 786)
	rds_sqlagent	Creating an SSIS proxy (p. 783)
SSRS	rds_drop_ssrs	Deleting databases (p. 796)

Local time zone for Microsoft SQL Server DB instances

The time zone of an Amazon RDS DB instance running Microsoft SQL Server is set by default. The current default is Coordinated Universal Time (UTC). You can set the time zone of your DB instance to a local time zone instead, to match the time zone of your applications.

You set the time zone when you first create your DB instance. You can create your DB instance by using the [AWS Management Console](#), the Amazon RDS API [CreateDBInstance](#) action, or the AWS CLI [create-db-instance](#) command.

If your DB instance is part of a Multi-AZ deployment (using SQL Server DBM or AGs), then when you fail over, your time zone remains the local time zone that you set. For more information, see [Multi-AZ deployments using Microsoft SQL Server Database Mirroring or Always On availability groups \(p. 643\)](#).

When you request a point-in-time restore, you specify the time to restore to. The time is shown in your local time zone. For more information, see [Restoring a DB instance to a specified time \(p. 389\)](#).

The following are limitations to setting the local time zone on your DB instance:

- You can't modify the time zone of an existing SQL Server DB instance.
- You can't restore a snapshot from a DB instance in one time zone to a DB instance in a different time zone.
- We strongly recommend that you don't restore a backup file from one time zone to a different time zone. If you restore a backup file from one time zone to a different time zone, you must audit your queries and applications for the effects of the time zone change. For more information, see [Importing and exporting SQL Server databases \(p. 671\)](#).

Supported time zones

You can set your local time zone to one of the values listed in the following table.

Time zones supported for Amazon RDS on SQL Server

Time zone	Standard time offset	Description	Notes
Afghanistan Standard Time	(UTC+04:30)	Kabul	This time zone doesn't observe daylight saving time.
Alaskan Standard Time	(UTC–09:00)	Alaska	
Aleutian Standard Time	(UTC–10:00)	Aleutian Islands	
Altai Standard Time	(UTC+07:00)	Barnaul, Gorno-Altaysk	
Arab Standard Time	(UTC+03:00)	Kuwait, Riyadh	This time zone doesn't observe daylight saving time.
Arabian Standard Time	(UTC+04:00)	Abu Dhabi, Muscat	
Arabic Standard Time	(UTC+03:00)	Baghdad	This time zone doesn't observe daylight saving time.
Argentina Standard Time	(UTC–03:00)	City of Buenos Aires	This time zone doesn't observe daylight saving time.
Astrakhan Standard Time	(UTC+04:00)	Astrakhan, Ulyanovsk	
Atlantic Standard Time	(UTC–04:00)	Atlantic Time (Canada)	
AUS Central Standard Time	(UTC+09:30)	Darwin	This time zone doesn't observe daylight saving time.
Aus Central W. Standard Time	(UTC+08:45)	Eucla	
AUS Eastern Standard Time	(UTC+10:00)	Canberra, Melbourne, Sydney	
Azerbaijan Standard Time	(UTC+04:00)	Baku	

Time zone	Standard time offset	Description	Notes
Azores Standard Time	(UTC-01:00)	Azores	
Bahia Standard Time	(UTC-03:00)	Salvador	
Bangladesh Standard Time	(UTC+06:00)	Dhaka	This time zone doesn't observe daylight saving time.
Belarus Standard Time	(UTC+03:00)	Minsk	This time zone doesn't observe daylight saving time.
Bougainville Standard Time	(UTC+11:00)	Bougainville Island	
Canada Central Standard Time	(UTC-06:00)	Saskatchewan	This time zone doesn't observe daylight saving time.
Cape Verde Standard Time	(UTC-01:00)	Cabo Verde Is.	This time zone doesn't observe daylight saving time.
Caucasus Standard Time	(UTC+04:00)	Yerevan	
Cen. Australia Standard Time	(UTC+09:30)	Adelaide	
Central America Standard Time	(UTC-06:00)	Central America	This time zone doesn't observe daylight saving time.
Central Asia Standard Time	(UTC+06:00)	Astana	This time zone doesn't observe daylight saving time.
Central Brazilian Standard Time	(UTC-04:00)	Cuiaba	
Central Europe Standard Time	(UTC+01:00)	Belgrade, Bratislava, Budapest, Ljubljana, Prague	
Central European Standard Time	(UTC+01:00)	Sarajevo, Skopje, Warsaw, Zagreb	
Central Pacific Standard Time	(UTC+11:00)	Solomon Islands, New Caledonia	This time zone doesn't observe daylight saving time.
Central Standard Time	(UTC-06:00)	Central Time (US and Canada)	
Central Standard Time (Mexico)	(UTC-06:00)	Guadalajara, Mexico City, Monterrey	
Chatham Islands Standard Time	(UTC+12:45)	Chatham Islands	

Time zone	Standard time offset	Description	Notes
China Standard Time	(UTC+08:00)	Beijing, Chongqing, Hong Kong, Urumqi	This time zone doesn't observe daylight saving time.
Cuba Standard Time	(UTC-05:00)	Havana	
Dateline Standard Time	(UTC-12:00)	International Date Line West	This time zone doesn't observe daylight saving time.
E. Africa Standard Time	(UTC+03:00)	Nairobi	This time zone doesn't observe daylight saving time.
E. Australia Standard Time	(UTC+10:00)	Brisbane	This time zone doesn't observe daylight saving time.
E. Europe Standard Time	(UTC+02:00)	Chisinau	
E. South America Standard Time	(UTC-03:00)	Brasilia	
Easter Island Standard Time	(UTC-06:00)	Easter Island	
Eastern Standard Time	(UTC-05:00)	Eastern Time (US and Canada)	
Eastern Standard Time (Mexico)	(UTC-05:00)	Chetumal	
Egypt Standard Time	(UTC+02:00)	Cairo	
Ekaterinburg Standard Time	(UTC+05:00)	Ekaterinburg	
Fiji Standard Time	(UTC+12:00)	Fiji	
FLE Standard Time	(UTC+02:00)	Helsinki, Kyiv, Riga, Sofia, Tallinn, Vilnius	
Georgian Standard Time	(UTC+04:00)	Tbilisi	This time zone doesn't observe daylight saving time.
GMT Standard Time	(UTC)	Dublin, Edinburgh, Lisbon, London	This time zone isn't the same as Greenwich Mean Time. This time zone does observe daylight saving time.
Greenland Standard Time	(UTC-03:00)	Greenland	
Greenwich Standard Time	(UTC)	Monrovia, Reykjavik	This time zone doesn't observe daylight saving time.
GTB Standard Time	(UTC+02:00)	Athens, Bucharest	
Haiti Standard Time	(UTC-05:00)	Haiti	

Time zone	Standard time offset	Description	Notes
Hawaiian Standard Time	(UTC-10:00)	Hawaii	
India Standard Time	(UTC+05:30)	Chennai, Kolkata, Mumbai, New Delhi	This time zone doesn't observe daylight saving time.
Iran Standard Time	(UTC+03:30)	Tehran	
Israel Standard Time	(UTC+02:00)	Jerusalem	
Jordan Standard Time	(UTC+02:00)	Amman	
Kaliningrad Standard Time	(UTC+02:00)	Kaliningrad	
Kamchatka Standard Time	(UTC+12:00)	Petropavlovsk-Kamchatsky – Old	
Korea Standard Time	(UTC+09:00)	Seoul	This time zone doesn't observe daylight saving time.
Libya Standard Time	(UTC+02:00)	Tripoli	
Line Islands Standard Time	(UTC+14:00)	Kiritimati Island	
Lord Howe Standard Time	(UTC+10:30)	Lord Howe Island	
Magadan Standard Time	(UTC+11:00)	Magadan	This time zone doesn't observe daylight saving time.
Magallanes Standard Time	(UTC-03:00)	Punta Arenas	
Marquesas Standard Time	(UTC-09:30)	Marquesas Islands	
Mauritius Standard Time	(UTC+04:00)	Port Louis	This time zone doesn't observe daylight saving time.
Middle East Standard Time	(UTC+02:00)	Beirut	
Montevideo Standard Time	(UTC-03:00)	Montevideo	
Morocco Standard Time	(UTC+01:00)	Casablanca	
Mountain Standard Time	(UTC-07:00)	Mountain Time (US and Canada)	
Mountain Standard Time (Mexico)	(UTC-07:00)	Chihuahua, La Paz, Mazatlan	
Myanmar Standard Time	(UTC+06:30)	Yangon (Rangoon)	This time zone doesn't observe daylight saving time.
N. Central Asia Standard Time	(UTC+07:00)	Novosibirsk	
Namibia Standard Time	(UTC+02:00)	Windhoek	

Time zone	Standard time offset	Description	Notes
Nepal Standard Time	(UTC+05:45)	Kathmandu	This time zone doesn't observe daylight saving time.
New Zealand Standard Time	(UTC+12:00)	Auckland, Wellington	
Newfoundland Standard Time	(UTC−03:30)	Newfoundland	
Norfolk Standard Time	(UTC+11:00)	Norfolk Island	
North Asia East Standard Time	(UTC+08:00)	Irkutsk	
North Asia Standard Time	(UTC+07:00)	Krasnoyarsk	
North Korea Standard Time	(UTC+09:00)	Pyongyang	
Omsk Standard Time	(UTC+06:00)	Omsk	
Pacific SA Standard Time	(UTC−03:00)	Santiago	
Pacific Standard Time	(UTC−08:00)	Pacific Time (US and Canada)	
Pacific Standard Time (Mexico)	(UTC−08:00)	Baja California	
Pakistan Standard Time	(UTC+05:00)	Islamabad, Karachi	This time zone doesn't observe daylight saving time.
Paraguay Standard Time	(UTC−04:00)	Asuncion	
Romance Standard Time	(UTC+01:00)	Brussels, Copenhagen, Madrid, Paris	
Russia Time Zone 10	(UTC+11:00)	Chokurdakh	
Russia Time Zone 11	(UTC+12:00)	Anadyr, Petropavlovsk-Kamchatsky	
Russia Time Zone 3	(UTC+04:00)	Izhevsk, Samara	
Russian Standard Time	(UTC+03:00)	Moscow, St. Petersburg, Volgograd	This time zone doesn't observe daylight saving time.
SA Eastern Standard Time	(UTC−03:00)	Cayenne, Fortaleza	This time zone doesn't observe daylight saving time.
SA Pacific Standard Time	(UTC−05:00)	Bogota, Lima, Quito, Rio Branco	This time zone doesn't observe daylight saving time.
SA Western Standard Time	(UTC−04:00)	Georgetown, La Paz, Manaus, San Juan	This time zone doesn't observe daylight saving time.

Time zone	Standard time offset	Description	Notes
Saint Pierre Standard Time	(UTC-03:00)	Saint Pierre and Miquelon	
Sakhalin Standard Time	(UTC+11:00)	Sakhalin	
Samoa Standard Time	(UTC+13:00)	Samoa	
Sao Tome Standard Time	(UTC+01:00)	Sao Tome	
Saratov Standard Time	(UTC+04:00)	Saratov	
SE Asia Standard Time	(UTC+07:00)	Bangkok, Hanoi, Jakarta	This time zone doesn't observe daylight saving time.
Singapore Standard Time	(UTC+08:00)	Kuala Lumpur, Singapore	This time zone doesn't observe daylight saving time.
South Africa Standard Time	(UTC+02:00)	Harare, Pretoria	This time zone doesn't observe daylight saving time.
Sri Lanka Standard Time	(UTC+05:30)	Sri Jayawardenepura	This time zone doesn't observe daylight saving time.
Sudan Standard Time	(UTC+02:00)	Khartoum	
Syria Standard Time	(UTC+02:00)	Damascus	
Taipei Standard Time	(UTC+08:00)	Taipei	This time zone doesn't observe daylight saving time.
Tasmania Standard Time	(UTC+10:00)	Hobart	
Tocantins Standard Time	(UTC-03:00)	Araguaina	
Tokyo Standard Time	(UTC+09:00)	Osaka, Sapporo, Tokyo	This time zone doesn't observe daylight saving time.
Tomsk Standard Time	(UTC+07:00)	Tomsk	
Tonga Standard Time	(UTC+13:00)	Nuku'alofa	This time zone doesn't observe daylight saving time.
Transbaikal Standard Time	(UTC+09:00)	Chita	
Turkey Standard Time	(UTC+03:00)	Istanbul	
Turks And Caicos Standard Time	(UTC-05:00)	Turks and Caicos	
Ulaanbaatar Standard Time	(UTC+08:00)	Ulaanbaatar	This time zone doesn't observe daylight saving time.

Time zone	Standard time offset	Description	Notes
US Eastern Standard Time	(UTC-05:00)	Indiana (East)	
US Mountain Standard Time	(UTC-07:00)	Arizona	This time zone doesn't observe daylight saving time.
UTC	UTC	Coordinated Universal Time	This time zone doesn't observe daylight saving time.
UTC-02	(UTC-02:00)	Coordinated Universal Time-02	This time zone doesn't observe daylight saving time.
UTC-08	(UTC-08:00)	Coordinated Universal Time-08	
UTC-09	(UTC-09:00)	Coordinated Universal Time-09	
UTC-11	(UTC-11:00)	Coordinated Universal Time-11	This time zone doesn't observe daylight saving time.
UTC+12	(UTC+12:00)	Coordinated Universal Time+12	This time zone doesn't observe daylight saving time.
UTC+13	(UTC+13:00)	Coordinated Universal Time+13	
Venezuela Standard Time	(UTC-04:00)	Caracas	This time zone doesn't observe daylight saving time.
Vladivostok Standard Time	(UTC+10:00)	Vladivostok	
Volgograd Standard Time	(UTC+04:00)	Volgograd	
W. Australia Standard Time	(UTC+08:00)	Perth	This time zone doesn't observe daylight saving time.
W. Central Africa Standard Time	(UTC+01:00)	West Central Africa	This time zone doesn't observe daylight saving time.
W. Europe Standard Time	(UTC+01:00)	Amsterdam, Berlin, Bern, Rome, Stockholm, Vienna	
W. Mongolia Standard Time	(UTC+07:00)	Hovd	
West Asia Standard Time	(UTC+05:00)	Ashgabat, Tashkent	This time zone doesn't observe daylight saving time.

Time zone	Standard time offset	Description	Notes
West Bank Standard Time	(UTC+02:00)	Gaza, Hebron	
West Pacific Standard Time	(UTC+10:00)	Guam, Port Moresby	This time zone doesn't observe daylight saving time.
Yakutsk Standard Time	(UTC+09:00)	Yakutsk	

Licensing Microsoft SQL Server on Amazon RDS

When you set up an Amazon RDS DB instance for Microsoft SQL Server, the software license is included.

This means that you don't need to purchase SQL Server licenses separately. AWS holds the license for the SQL Server database software. Amazon RDS pricing includes the software license, underlying hardware resources, and Amazon RDS management capabilities.

Amazon RDS supports the following Microsoft SQL Server editions:

- Enterprise
- Standard
- Web
- Express

Note

Licensing for SQL Server Web Edition supports only public and internet-accessible webpages, websites, web applications, and web services. This level of support is required for compliance with Microsoft's usage rights. For more information, see [AWS service terms](#).

Amazon RDS supports Multi-AZ deployments for DB instances running Microsoft SQL Server by using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). There are no additional licensing requirements for Multi-AZ deployments. For more information, see [Multi-AZ deployments for Microsoft SQL Server \(p. 698\)](#).

Restoring license-terminated DB instances

Amazon RDS takes snapshots of license-terminated DB instances. If your instance is terminated for licensing issues, you can restore it from the snapshot to a new DB instance. New DB instances have a license included.

For more information, see [Restoring license-terminated DB instances \(p. 819\)](#).

Development and test

Because of licensing requirements, we can't offer SQL Server Developer Edition on Amazon RDS. You can use Express Edition for many development, testing, and other nonproduction needs. However, if you need the full feature capabilities of an enterprise-level installation of SQL Server for development, you can download and install SQL Server Developer Edition (and other MSDN products) on Amazon EC2. Dedicated infrastructure isn't required for Developer Edition. By using your own host, you also gain access to other programmability features that are not accessible on Amazon RDS. For more information on the difference between SQL Server editions, see [Editions and supported features of SQL Server 2017](#) in the Microsoft documentation.

Connecting to a DB instance running the Microsoft SQL Server database engine

After Amazon RDS provisions your DB instance, you can use any standard SQL client application to connect to the DB instance. In this topic, you connect to your DB instance by using either Microsoft SQL Server Management Studio (SSMS) or SQL Workbench/J.

For an example that walks you through the process of creating and connecting to a sample DB instance, see [Creating a Microsoft SQL Server DB instance and connecting to it \(p. 80\)](#).

Connecting to your DB instance with Microsoft SQL Server Management Studio

In this procedure, you connect to your sample DB instance by using Microsoft SQL Server Management Studio (SSMS). To download a standalone version of this utility, see [Download SQL Server Management Studio \(SSMS\)](#) in the Microsoft documentation.

To connect to a DB instance using SSMS

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region of your DB instance.
3. Find the Domain Name System (DNS) name and port number for your DB instance:
 - a. Open the RDS console and choose **Databases** to display a list of your DB instances.
 - b. Choose the SQL Server DB instance name to display its details.
 - c. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

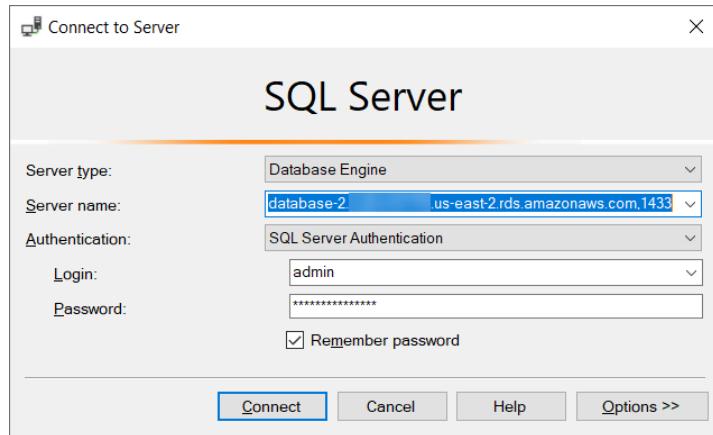

The screenshot shows the Amazon RDS console interface for a DB instance named 'database-2'. The 'Summary' tab is visible at the top, showing basic details like DB identifier and role. Below it, the 'Connectivity & security' tab is selected, showing the endpoint (database-2.REDACTED.us-east-2.rds.amazonaws.com) and port (1433).

Summary	
DB identifier	database-2
Role	Instance

Connectivity & security	
Endpoint	database-2. REDACTED .us-east-2.rds.amazonaws.com
Port	1433

4. Start SQL Server Management Studio.

The **Connect to Server** dialog box appears.

5. Provide the information for your DB instance:

- a. For **Server type**, choose **Database Engine**.
- b. For **Server name**, enter the DNS name and port number of your DB instance, separated by a comma.

Important

Change the colon between the DNS name and port number to a comma.

For example, your server name should look like the following.

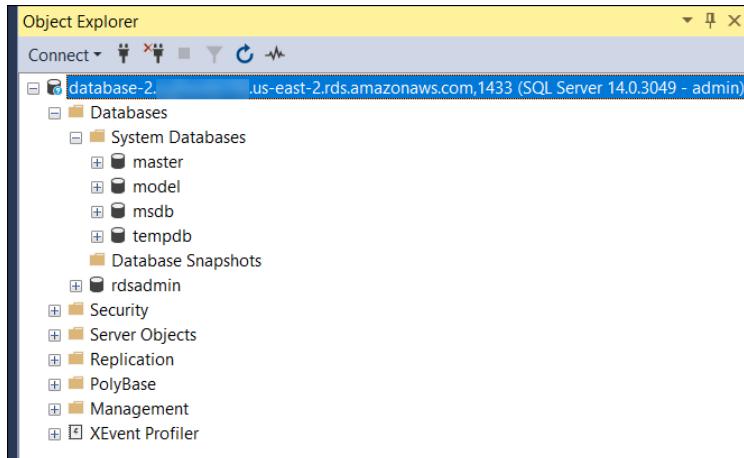

database-2.cg034itsfake.us-east-1.rds.amazonaws.com,1433

- c. For **Authentication**, choose **SQL Server Authentication**.
- d. For **Login**, enter the master user name for your DB instance.
- e. For **Password**, enter the password for your DB instance.

6. Choose **Connect**.

After a few moments, SSMS connects to your DB instance. If you can't connect to your DB instance, see [Security group considerations \(p. 660\)](#) and [Troubleshooting connections to your SQL Server DB instance \(p. 661\)](#).

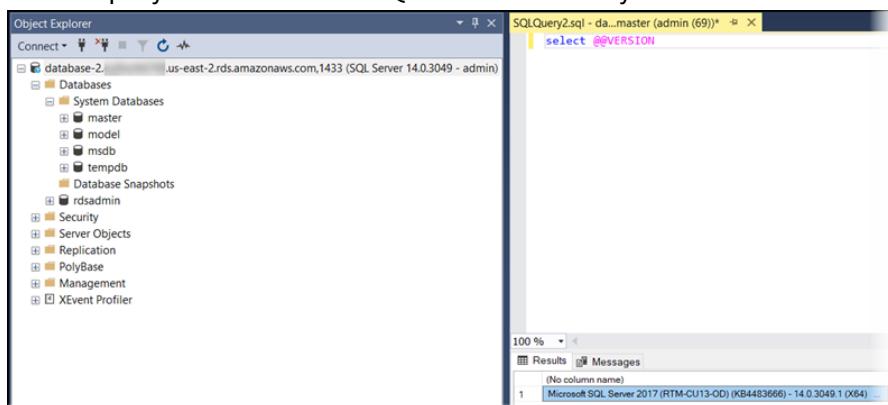

7. Your SQL Server DB instance comes with SQL Server's standard built-in system databases (`master`, `model`, `msdb`, and `tempdb`). To explore the system databases, do the following:
 - a. In SSMS, on the **View** menu, choose **Object Explorer**.
 - b. Expand your DB instance, expand **Databases**, and then expand **System Databases**.

8. Your SQL Server DB instance also comes with a database named `rdsadmin`. Amazon RDS uses this database to store the objects that it uses to manage your database. The `rdsadmin` database also includes stored procedures that you can run to perform advanced tasks. For more information, see [Common DBA tasks for Microsoft SQL Server \(p. 809\)](#).
9. You can now start creating your own databases and running queries against your DB instance and databases as usual. To run a test query against your DB instance, do the following:
 - a. In SSMS, on the **File** menu point to **New** and then choose **Query with Current Connection**.
 - b. Enter the following SQL query.

```
select @@VERSION
```

- c. Run the query. SSMS returns the SQL Server version of your Amazon RDS DB instance.

Connecting to your DB instance with SQL Workbench/J

This example shows how to connect to a DB instance running the Microsoft SQL Server database engine by using the SQL Workbench/J database tool. To download SQL Workbench/J, see [SQL Workbench/J](#).

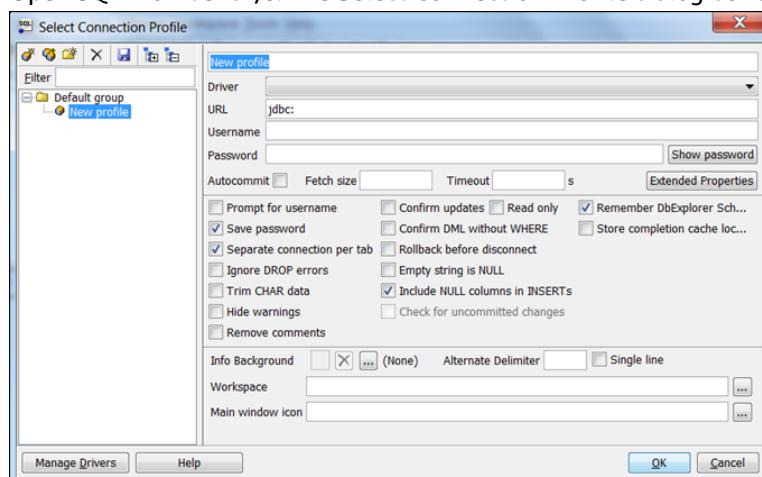

SQL Workbench/J uses JDBC to connect to your DB instance. You also need the JDBC driver for SQL Server. To download this driver, see [Microsoft JDBC drivers 4.1 \(preview\) and 4.0 for SQL Server](#).

To connect to a DB instance using SQL Workbench/J

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the upper-right corner of the Amazon RDS console, choose the AWS Region of your DB instance.
3. Find the DNS name and port number for your DB instance:
 - a. Open the RDS console, then choose **Databases** to display a list of your DB instances.
 - b. Choose the name of your SQL Server DB instance to display its details.

The screenshot shows the 'Summary' tab of the RDS console for a database instance named 'database-2'. It displays basic information like DB identifier, CPU usage, and role. Below it, the 'Connectivity & security' tab is selected, showing the endpoint and port details: Endpoint is 'database-2.[REDACTED].us-east-2.rds.amazonaws.com' and Port is '1433'.

- c. On the **Connectivity** tab, copy the endpoint. Also, note the port used by the DB instance.
4. Open SQL Workbench/J. The **Select Connection Profile** dialog box appears, as shown following.

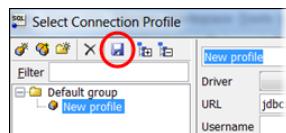

5. In the first box at the top of the dialog box, enter a name for the profile.
6. For **Driver**, choose **SQL JDBC 4.0**.

7. For **URL**, enter `jdbc:sqlserver://`, then enter the endpoint of your DB instance. For example, the URL value might be the following.

```
jdbc:sqlserver://sqlsvr-pdz.abcd12340.us-west-2.rds.amazonaws.com:1433
```

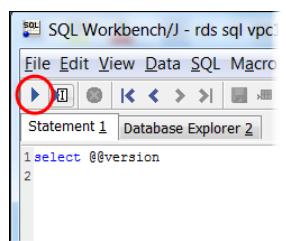

8. For **Username**, enter the master user name for the DB instance.
9. For **Password**, enter the password for the master user.
10. Choose the save icon in the dialog toolbar, as shown following.

11. Choose **OK**. After a few moments, SQL Workbench/J connects to your DB instance. If you can't connect to your DB instance, see [Security group considerations \(p. 660\)](#) and [Troubleshooting connections to your SQL Server DB instance \(p. 661\)](#).
12. In the query pane, enter the following SQL query.

```
select @@VERSION
```

13. Choose the **Execute** icon in the toolbar, as shown following.

The query returns the version information for your DB instance, similar to the following.

```
Microsoft SQL Server 2012 - 11.0.2100.60 (X64)
```

Security group considerations

To connect to your DB instance, your DB instance must be associated with a security group. This security group contains the IP addresses and network configuration that you use to access the DB instance. You might have associated your DB instance with an appropriate security group when you created your DB instance. If you assigned a default, no-configured security group when you created your DB instance, your DB instance firewall prevents connections.

In some cases, you might need to create a new security group to enable access. If so, the type of security group to create depends on what Amazon EC2 platform your DB instance is on. To determine your platform, see [Determining whether you are using the EC2-VPC or EC2-Classic platform \(p. 1718\)](#). In general, if your DB instance is on the EC2-Classic platform, you create a DB security group. If your DB instance is on the VPC platform, you create a VPC security group.

For instructions on creating a new security group, see [Controlling access with security groups \(p. 1699\)](#). For a topic that walks you through the process of setting up rules for your VPC security group, see [Tutorial: Create an Amazon VPC for use with a DB instance \(p. 1737\)](#).

After you have created the new security group, modify your DB instance to associate it with the security group. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

You can enhance security by using SSL to encrypt connections to your DB instance. For more information, see [Using SSL with a Microsoft SQL Server DB instance \(p. 704\)](#).

Troubleshooting connections to your SQL Server DB instance

The following table shows error messages that you might encounter when you attempt to connect to your SQL Server DB instance. For more information on connection issues, see [Can't connect to Amazon RDS DB instance \(p. 1746\)](#).

Issue	Troubleshooting suggestions
Could not open a connection to SQL Server – Microsoft SQL Server, Error: 53	<p>Make sure that you specified the server name correctly. For Server name, enter the DNS name and port number of your sample DB instance, separated by a comma.</p> <p>Important If you have a colon between the DNS name and port number, change the colon to a comma. Your server name should look like the following example.</p> <div style="border: 1px solid black; padding: 5px; width: fit-content;">sample-instance.cg034itsfake.us-east-1.rds.amazonaws.com,1433</div>
No connection could be made because the target machine actively refused it – Microsoft SQL Server, Error: 10061	You were able to reach the DB instance but the connection was refused. This issue is usually caused by specifying the user name or password incorrectly. Verify the user name and password, then retry.
A network-related or instance-specific error occurred while establishing a connection to SQL Server. The server was not found or was not accessible... The wait operation timed out – Microsoft SQL Server, Error: 258	<p>The access rules enforced by your local firewall and the IP addresses authorized to access your DB instance might not match. The problem is most likely the inbound rules in your security group.</p> <p>Your database instance must be publicly accessible. To connect to it from outside of the VPC, the instance must have a public IP address assigned.</p>

Updating applications to connect to Microsoft SQL Server DB instances using new SSL/TLS certificates

As of September 19, 2019, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances. If they do, you can further check whether those applications require certificate verification to connect.

Note

Some applications are configured to connect to SQL Server DB instances only if they can successfully verify the certificate on the server.

For such applications, you must update your client application trust stores to include the new CA certificates.

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see [Rotating your SSL/TLS certificate \(p. 1636\)](#). For more information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 1634\)](#). For information about using SSL/TLS with Microsoft SQL Server DB instances, see [Using SSL with a Microsoft SQL Server DB instance \(p. 704\)](#).

Topics

- [Determining whether any applications are connecting to your Microsoft SQL Server DB instance using SSL \(p. 662\)](#)
- [Determining whether a client requires certificate verification in order to connect \(p. 663\)](#)
- [Updating your application trust store \(p. 664\)](#)

Determining whether any applications are connecting to your Microsoft SQL Server DB instance using SSL

Check the DB instance configuration for the value of the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off). If the `rds.force_ssl` parameter is set to 1 (on), clients are required to use SSL/TLS for connections. For more information about parameter groups, see [Working with DB parameter groups \(p. 228\)](#). You can also find the setting for this parameter in the `sys.dm_server_registry` DMV.

Run the following query to get the current encryption option for all the open connections to a DB instance. The column `ENCRYPT_OPTION` returns `TRUE` if the connection is encrypted.

```
select SESSION_ID,
       ENCRYPT_OPTION,
       NET_TRANSPORT,
       AUTH_SCHEME
  from SYS.DM_EXEC_CONNECTIONS
```

This query shows only the current connections. It doesn't show whether applications that have connected and disconnected in the past have used SSL.

Determining whether a client requires certificate verification in order to connect

You can check whether different types of clients require certificate verification to connect.

Note

If you use connectors other than the ones listed, see the specific connector's documentation for information about how it enforces encrypted connections. For more information, see [Connection modules for Microsoft SQL databases](#) in the Microsoft SQL Server documentation.

SQL Server Management Studio

Check whether encryption is enforced for SQL Server Management Studio connections:

1. Launch SQL Server Management Studio.
2. For **Connect to server**, enter the server information, login user name, and password.
3. Choose **Options**.
4. Check if **Encrypt connection** is selected in the connect page.

For more information about SQL Server Management Studio, see [Use SQL Server Management Studio](#).

Sqlcmd

The following example with the `sqlcmd` client shows how to check a script's SQL Server connection to determine whether successful connections require a valid certificate. For more information, see [Connecting with sqlcmd](#) in the Microsoft SQL Server documentation.

When using `sqlcmd`, an SSL connection requires verification against the server certificate if you use the `-N` command argument to encrypt connections, as in the following example.

```
$ sqlcmd -N -S dbinstance.rds.amazonaws.com -d ExampleDB
```

Note

If `sqlcmd` is invoked with the `-C` option, it trusts the server certificate, even if that doesn't match the client-side trust store.

ADO.NET

In the following example, the application connects using SSL, and the server certificate must be verified.

```
using SQLC = Microsoft.Data.SqlClient;  
  
...  
  
static public void Main()  
{  
    using (var connection = new SQLC.SqlConnection(  
        "Server=tcp:dbinstance.rds.amazonaws.com;" +  
        "Database=ExampleDB;User ID=LOGIN_NAME;" +  
        "Password=YOUR_PASSWORD;" +  
        "Encrypt=True;TrustServerCertificate=False;"  
    ))
```

```
{  
    connection.Open();  
    ...  
}
```

Java

In the following example, the application connects using SSL, and the server certificate must be verified.

```
String connectionUrl =  
    "jdbc:sqlserver://dbinstance.rds.amazonaws.com;" +  
    "databaseName=ExampleDB;integratedSecurity=true;" +  
    "encrypt=true;trustServerCertificate=false";
```

To enable SSL encryption for clients that connect using JDBC, you might need to add the Amazon RDS certificate to the Java CA certificate store. For instructions, see [Configuring the client for encryption](#) in the Microsoft SQL Server documentation. You can also provide the trusted CA certificate file name directly by appending `trustStore=path-to-certificate-trust-store-file` to the connection string.

Note

If you use `TrustServerCertificate=true` (or its equivalent) in the connection string, the connection process skips the trust chain validation. In this case, the application connects even if the certificate can't be verified. Using `TrustServerCertificate=false` enforces certificate validation and is a best practice.

Updating your application trust store

You can update the trust store for applications that use Microsoft SQL Server. For instructions, see [Encrypting specific connections \(p. 705\)](#). Also, see [Configuring the client for encryption](#) in the Microsoft SQL Server documentation.

If you are using an operating system other than Microsoft Windows, see the software distribution documentation for SSL/TLS implementation for information about adding a new root CA certificate. For example, OpenSSL and GnuTLS are popular options. Use the implementation method to add trust to the RDS root CA certificate. Microsoft provides instructions for configuring certificates on some systems.

Note

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

Updating your application trust store for JDBC

You can update the trust store for applications that use JDBC for SSL/TLS connections.

To update the trust store for JDBC applications

1. Download the 2019 root certificate that works for all AWS Regions and put the file in the trust store directory.

For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 1634\)](#).
2. Convert the certificate to .der format using the following command.

```
openssl x509 -outform der -in rds-ca-2019-root.pem -out rds-ca-2019-root.der
```

Replace the file name with the one that you downloaded.

3. Import the certificate into the key store using the following command.

```
keytool -import -alias rds-root -keystore clientkeystore -file rds-ca-2019-root.der
```

4. Confirm that the key store was updated successfully.

```
keytool -list -v -keystore clientkeystore.jks
```

Enter the key store password when you are prompted for it.

Your output should contain the following.

```
rds-root,date, trustedCertEntry,  
Certificate fingerprint (SHA1):  
D4:0D:DB:29:E3:75:0D:FF:A6:71:C3:14:0B:BF:5F:47:8D:1C:80:96  
# This fingerprint should match the output from the below command  
openssl x509 -fingerprint -in rds-ca-2019-root.pem -noout
```

Important

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-2019 certificates. For instructions, see step 3 in [Updating your CA certificate by modifying your DB instance \(p. 1636\)](#).

Upgrading the Microsoft SQL Server DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for SQL Server DB instances: major version upgrades and minor version upgrades.

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you test the upgrade by following the steps described in [Testing an upgrade \(p. 669\)](#).

In contrast, *minor version upgrades* include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance.

Amazon RDS on SQL Server doesn't support automatic minor version upgrades. You can confirm this by using the `describe-db-engine-versions` AWS CLI command. For example:

```
aws rds describe-db-engine-versions --engine sqlserver-se --engine-version 14.00.3049.1.v1
```

In this example, the CLI command returns the following response that indicates that the upgrade will *not* be automatic, even if **Auto minor version upgrade** had been enabled:

```
...
"ValidUpgradeTarget": [
    {
        "Engine": "sqlserver-se",
        "EngineVersion": "14.00.3192.2.v1",
        "Description": "SQL Server 2017 14.00.3192.2.v1",
        "AutoUpgrade": false,
        "IsMajorVersionUpgrade": false
    }
]
...
```

For more information about performing upgrades, see [Upgrading a SQL Server DB instance \(p. 669\)](#). For information about what SQL Server versions are available on Amazon RDS, see [Microsoft SQL Server on Amazon RDS \(p. 630\)](#).

Topics

- [Overview of upgrading \(p. 666\)](#)
- [Major version upgrades \(p. 667\)](#)
- [Multi-AZ and in-memory optimization considerations \(p. 668\)](#)
- [Option and parameter group considerations \(p. 668\)](#)
- [Testing an upgrade \(p. 669\)](#)
- [Upgrading a SQL Server DB instance \(p. 669\)](#)
- [Upgrading deprecated DB instances before support ends \(p. 670\)](#)

Overview of upgrading

Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the DB instance before any upgrade changes have been made. If the upgrade doesn't work for your databases,

you can restore this snapshot to create a DB instance running the old version. The second DB snapshot is taken after the upgrade completes.

Note

Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

After an upgrade is complete, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore the DB snapshot that was taken before the upgrade to create a new DB instance.

During a minor or major version upgrade of SQL Server, the **Free Storage Space** and **Disk Queue Depth** metrics will display -1. After the upgrade is complete, both metrics will return to normal.

Major version upgrades

Amazon RDS currently supports the following major version upgrades to a Microsoft SQL Server DB instance.

You can upgrade your existing DB instance to SQL Server 2017 or 2019 from any version except SQL Server 2008. To upgrade from SQL Server 2008, first upgrade to one of the other versions.

Current version	Supported upgrade versions
SQL Server 2017	SQL Server 2019
SQL Server 2016	SQL Server 2019 SQL Server 2017
SQL Server 2014	SQL Server 2019 SQL Server 2017 SQL Server 2016
SQL Server 2012	SQL Server 2019 SQL Server 2017 SQL Server 2016 SQL Server 2014
SQL Server 2008 R2 (Deprecated)	SQL Server 2016 SQL Server 2014 SQL Server 2012

You can use an AWS CLI query, such as the following example, to find the available upgrades for a particular database engine version.

Example

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine sqlserver-se \
```

```
--engine-version 14.00.3049.1.v1 \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" \
--output table
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine sqlserver-se ^
--engine-version 14.00.3049.1.v1 ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" ^
--output table
```

The output shows that you can upgrade version 14.00.3049.1 to the latest SQL Server 2017 or 2019 version.

```
-----
|DescribeDBEngineVersions|
+-----+
|   EngineVersion      |
+-----+
| 14.00.3294.2.v1     |
| 15.00.4043.16.v1    |
+-----+
```

Database compatibility level

You can use Microsoft SQL Server database compatibility levels to adjust some database behaviors to mimic previous versions of SQL Server. For more information, see [Compatibility level](#) in the Microsoft documentation.

When you upgrade your DB instance, all existing databases remain at their original compatibility level. For example, if you upgrade from SQL Server 2012 to SQL Server 2014, all existing databases have a compatibility level of 110. Any new database created after the upgrade have compatibility level 120.

You can change the compatibility level of a database by using the ALTER DATABASE command. For example, to change a database named `customeracct` to be compatible with SQL Server 2014, issue the following command:

```
ALTER DATABASE customeracct SET COMPATIBILITY_LEVEL = 120
```

Multi-AZ and in-memory optimization considerations

Amazon RDS supports Multi-AZ deployments for DB instances running Microsoft SQL Server by using SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). For more information, see [Multi-AZ deployments for Microsoft SQL Server \(p. 698\)](#).

If your DB instance is in a Multi-AZ deployment, both the primary and standby instances are upgraded. Amazon RDS does rolling upgrades. You have an outage only for the duration of a failover.

SQL Server 2014 through 2019 Enterprise Edition support in-memory optimization.

Option and parameter group considerations

Option group considerations

If your DB instance uses a custom option group, in some cases Amazon RDS can't automatically assign your DB instance a new option group. For example, when you upgrade to a new major version. In that

case, you must specify a new option group when you upgrade. We recommend that you create a new option group, and add the same options to it as your existing custom option group.

For more information, see [Creating an option group \(p. 214\)](#) or [Copying an option group \(p. 215\)](#).

Parameter group considerations

If your DB instance uses a custom parameter group, in some cases Amazon RDS can't automatically assign your DB instance a new parameter group. For example, when you upgrade to a new major version. In that case, you must specify a new parameter group when you upgrade. We recommend that you create a new parameter group, and configure the parameters as in your existing custom parameter group.

For more information, see [Creating a DB parameter group \(p. 229\)](#) or [Copying a DB parameter group \(p. 236\)](#).

Testing an upgrade

Before you perform a major version upgrade on your DB instance, you should thoroughly test your database, and all applications that access the database, for compatibility with the new version. We recommend that you use the following procedure.

To test a major version upgrade

1. Review [Upgrade SQL Server](#) in the Microsoft documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications.
2. If your DB instance uses a custom option group, create a new option group compatible with the new version you are upgrading to. For more information, see [Option group considerations \(p. 668\)](#).
3. If your DB instance uses a custom parameter group, create a new parameter group compatible with the new version you are upgrading to. For more information, see [Parameter group considerations \(p. 669\)](#).
4. Create a DB snapshot of the DB instance to be upgraded. For more information, see [Creating a DB snapshot \(p. 346\)](#).
5. Restore the DB snapshot to create a new test DB instance. For more information, see [Restoring from a DB snapshot \(p. 349\)](#).
6. Modify this new test DB instance to upgrade it to the new version, by using one of the following methods:
 - [Console \(p. 271\)](#)
 - [AWS CLI \(p. 272\)](#)
 - [RDS API \(p. 272\)](#)
7. Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage.
8. Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version. Implement any new tests needed to evaluate the impact of any compatibility issues you identified in step 1. Test all stored procedures and functions. Direct test versions of your applications to the upgraded DB instance.
9. If all tests pass, then perform the upgrade on your production DB instance. We recommend that you do not allow write operations to the DB instance until you confirm that everything is working correctly.

Upgrading a SQL Server DB instance

For information about manually or automatically upgrading a SQL Server DB instance, see the following:

- [Upgrading a DB instance engine version \(p. 271\)](#)
- [Best practices for upgrading SQL Server 2008 R2 to SQL Server 2016 on Amazon RDS for SQL Server](#)

Important

If you have any snapshots that are encrypted using AWS KMS, we recommend that you initiate an upgrade before support ends.

Upgrading deprecated DB instances before support ends

After a major version is deprecated, you can't install it on new DB instances. RDS will try to automatically upgrade all existing DB instances.

If you need to restore a deprecated DB instance, you can do point-in-time recovery (PITR) or restore a snapshot. Doing this gives you temporary access a DB instance that uses the version that is being deprecated. However, after a major version is fully deprecated, these DB instances will also be automatically upgraded to a supported version.

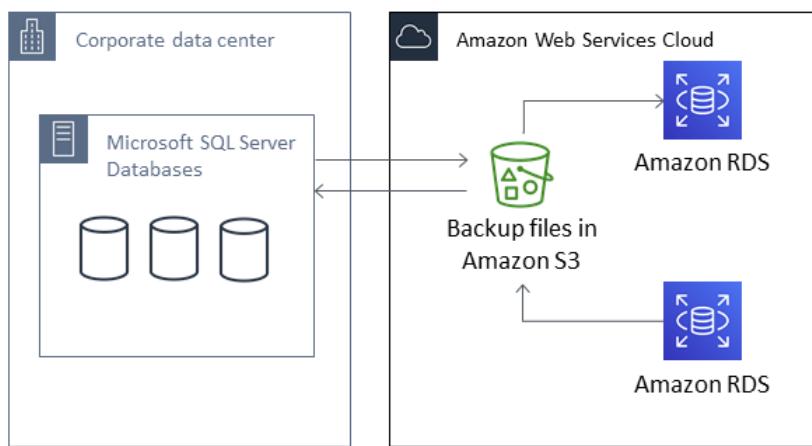

Importing and exporting SQL Server databases

Amazon RDS supports native backup and restore for Microsoft SQL Server databases using full backup files (.bak files). When you use RDS, you access files stored in Amazon S3 rather than using the local file system on the database server.

For example, you can create a full backup from your local server, store it on S3, and then restore it onto an existing Amazon RDS DB instance. You can also make backups from RDS, store them on S3, and then restore them wherever you want.

Native backup and restore is available in all AWS Regions for Single-AZ and Multi-AZ DB instances, including Multi-AZ DB instances with read replicas. Native backup and restore is available for all editions of Microsoft SQL Server supported on Amazon RDS.

The following diagram shows the supported scenarios.

Using native .bak files to back up and restore databases is usually the fastest way to back up and restore databases. There are many additional advantages to using native backup and restore. For example, you can do the following:

- Migrate databases to or from Amazon RDS.
- Move databases between RDS for SQL Server DB instances.
- Migrate data, schemas, stored procedures, triggers, and other database code inside .bak files.
- Backup and restore single databases, instead of entire DB instances.
- Create copies of databases for development, testing, training, and demonstrations.
- Store and transfer backup files with Amazon S3, for an added layer of protection for disaster recovery.

Limitations and recommendations

The following are some limitations to using native backup and restore:

- You can't back up to, or restore from, an Amazon S3 bucket in a different AWS Region from your Amazon RDS DB instance.
- We strongly recommend that you don't restore backups from one time zone to a different time zone. If you restore backups from one time zone to a different time zone, you must audit your queries and applications for the effects of the time zone change.
- Amazon S3 has a size limit of 5 TB per file. For native backups of larger databases, you can use multifile backup.

- The maximum database size that can be backed up to S3 depends on the available memory, CPU, I/O, and network resources on the DB instance. The larger the database, the more memory the backup agent consumes. Our testing shows that you can make a compressed backup of a 16-TB database on our newest-generation instance types from 2xlarge instance sizes and larger, given sufficient system resources.
- You can't back up to or restore from more than 10 backup files at the same time.
- A differential backup is based on the last full backup. For differential backups to work, you can't take a snapshot between the last full backup and the differential backup. If you want a differential backup, but a manual or automated snapshot exists, then do another full backup before proceeding with the differential backup.
- Differential and log restores aren't supported for databases with files that have their file_guid (unique identifier) set to NULL.
- You can run up to two backup or restore tasks at the same time.
- You can't perform native log backups from SQL Server on Amazon RDS.
- RDS supports native restores of databases up to 16 TB. Native restores of databases on SQL Server Express Edition are limited to 10 GB.
- You can't do a native backup during the maintenance window, or any time Amazon RDS is in the process of taking a snapshot of the database. If a native backup task overlaps with the RDS daily backup window, the native backup task is canceled.
- On Multi-AZ DB instances, you can only natively restore databases that are backed up in the full recovery model.
- Restoring from differential backups on Multi-AZ instances isn't supported.
- Calling the RDS procedures for native backup and restore within a transaction isn't supported.
- Use a symmetric AWS KMS customer master key (CMK) to encrypt your backups. Amazon RDS doesn't support asymmetric CMKs. For more information, see [Using symmetric and asymmetric keys](#) in the *AWS Key Management Service Developer Guide*.
- Native backup files are encrypted with the specified AWS KMS CMK using the "Encryption-Only" crypto mode. When you are restoring encrypted backup files, be aware that they were encrypted with the "Encryption-Only" crypto mode.
- You can't restore a database that contains a FILESTREAM file group.

If your database can be offline while the backup file is created, copied, and restored, we recommend that you use native backup and restore to migrate it to RDS. If your on-premises database can't be offline, we recommend that you use the AWS Database Migration Service to migrate your database to Amazon RDS. For more information, see [What is AWS Database Migration Service?](#)

Native backup and restore isn't intended to replace the data recovery capabilities of the cross-region snapshot copy feature. We recommend that you use snapshot copy to copy your database snapshot to another AWS Region for cross-region disaster recovery in Amazon RDS. For more information, see [Copying a snapshot \(p. 352\)](#).

Setting up for native backup and restore

To set up for native backup and restore, you need three components:

1. An Amazon S3 bucket to store your backup files.

You must have an S3 bucket to use for your backup files and then upload backups you want to migrate to RDS. If you already have an Amazon S3 bucket, you can use that. If you don't, you can [create a bucket](#). Alternatively, you can choose to have a new bucket created for you when you add the `SQLSERVER_BACKUP_RESTORE` option by using the AWS Management Console.

For information on using S3, see the *Amazon Simple Storage Service Getting Started Guide* for a simple introduction. For more depth, see the *Amazon Simple Storage Service Console User Guide*.

2. An AWS Identity and Access Management (IAM) role to access the bucket.

If you already have an IAM role, you can use that. You can choose to have a new IAM role created for you when you add the `SQLSERVER_BACKUP_RESTORE` option by using the AWS Management Console. Alternatively, you can create a new one manually.

If you want to create a new IAM role manually, take the approach discussed in the next section. Do the same if you want to attach trust relationships and permissions policies to an existing IAM role.

3. The SOL SERVER BACKUP RESTORE option added to an option group on your DB instance.

To enable native backup and restore on your DB instance, you add the `SQlSERVER_BACKUP_RESTORE` option to an option group on your DB instance. For more information and instructions, see [Support for native backup and restore in SQL Server \(p. 751\)](#).

Manually creating an IAM role for native backup and restore

If you want to manually create a new IAM role to use with native backup and restore, you can do so. In this case, you create a role to delegate permissions from the Amazon RDS service to your Amazon S3 bucket. When you create an IAM role, you attach a trust relationship and a permissions policy. The trust relationship allows RDS to assume this role. The permissions policy defines the actions this role can do. For more information about creating the role, see [Creating a role to delegate permissions to an AWS service](#).

For the native backup and restore feature, use trust relationships and permissions policies similar to the examples in this section. In the following example, we use the service principal name `rds.amazonaws.com` as an alias for all service accounts. In the other examples, we specify an Amazon Resource Name (ARN) to identify another account, user, or role that we're granting access to in the trust policy.

Example Trust relationship for native backup and restore

```
{  
    "Version": "2012-10-17",  
    "Statement":  
    [ {  
        "Effect": "Allow",  
        "Principal": {"Service": "rds.amazonaws.com"},  
        "Action": "sts:AssumeRole"  
    }]  
}
```

The following example uses an ARN to specify a resource. For more information on using ARNs, see [Amazon resource names \(ARNs\)](#).

Example Permissions policy for native backup and restore without encryption support

```
{
  "Version": "2012-10-17",
  "Statement":
  [
    {

Example Permissions policy for native backup and restore with encryption support

If you want to encrypt your backup files, include an encryption key in your permissions policy. For more information about encryption keys, see [Getting started](#) in the *AWS Key Management Service Developer Guide*.

Note

You must use a symmetric AWS KMS CMK to encrypt your backups. Amazon RDS doesn't support asymmetric CMKs. For more information, see [Using symmetric and asymmetric keys](#) in the *AWS Key Management Service Developer Guide*.

The IAM role must also be a key user and key administrator for the AWS KMS CMK, that is, it must be specified in the key policy. For more information, see [Creating symmetric CMKs](#) in the *AWS Key Management Service Developer Guide*.

```
{
    "Version": "2012-10-17",
    "Statement":
    [
        {
            "Effect": "Allow",
            "Action":
            [
                "kms:DescribeKey",
                "kms:GenerateDataKey",
                "kms:Encrypt",
                "kms:Decrypt"
            ],
            "Resource": "arn:aws:kms:region:account-id:key/key-id"
        },
        {
            "Effect": "Allow",
            "Action":
            [
                "s3>ListBucket",
                "s3:GetBucketLocation"
            ],
            "Resource": "arn:aws:s3:::bucket_name"
        },
        {

            "Action":
            [
                "s3:GetObject",
                "s3:PutObject",
                "s3>ListMultipartUploadParts",
                "s3:AbortMultipartUpload"
            ],
            "Resource": "arn:aws:s3:::bucket_name/*"
        }
    ]
}
```

```
        "s3:AbortMultipartUpload"
    ],
    "Resource": "arn:aws:s3:::bucket_name/*"
}
]
```

Using native backup and restore

After you have enabled and configured native backup and restore, you can start using it. First, you connect to your Microsoft SQL Server database, and then you call an Amazon RDS stored procedure to do the work. For instructions on connecting to your database, see [Connecting to a DB instance running the Microsoft SQL Server database engine \(p. 656\)](#).

Some of the stored procedures require that you provide an Amazon Resource Name (ARN) to your Amazon S3 bucket and file. The format for your ARN is `arn:aws:s3:::bucket_name/file_name.extension`. Amazon S3 doesn't require an account number or AWS Region in ARNs.

If you also provide an optional AWS KMS customer master key (CMK), the format for the ARN of the key is `arn:aws:kms:region:account-id:key/key-id`. For more information, see [Amazon resource names \(ARNs\) and AWS service namespaces](#). You must use a symmetric AWS KMS CMK to encrypt your backups. Amazon RDS doesn't support asymmetric CMKs. For more information, see [Using symmetric and asymmetric keys](#) in the [AWS Key Management Service Developer Guide](#).

Note

Whether or not you use a KMS CMK, the native backup and restore tasks enable server-side Advanced Encryption Standard (AES) 256-bit encryption by default for files uploaded to S3.

For instructions on how to call each stored procedure, see the following topics:

- [Backing up a database \(p. 675\)](#)
- [Restoring a database \(p. 678\)](#)
- [Restoring a log \(p. 680\)](#)
- [Finishing a database restore \(p. 681\)](#)
- [Working with partially restored databases \(p. 682\)](#)
- [Canceling a task \(p. 682\)](#)
- [Tracking the status of tasks \(p. 682\)](#)

Backing up a database

To back up your database, use the `rds_backup_database` stored procedure.

Note

You can't back up a database during the maintenance window, or while Amazon RDS is taking a snapshot.

Usage

```
exec msdb.dbo.rds_backup_database
@source_db_name='database_name',
@s3_arn_to_backup_to='arn:aws:s3:::bucket_name/file_name.extension',
[@kms_master_key_arn='arn:aws:kms:region:account-id:key/key-id'],
[@overwrite_s3_backup_file=0/1],
[@type='DIFFERENTIAL/FULL'],
[@number_of_files=n];
```

The following parameters are required:

- `@source_db_name` – The name of the database to back up.
- `@s3_arn_to_backup_to` – The ARN indicating the Amazon S3 bucket to use for the backup, plus the name of the backup file.

The file can have any extension, but `.bak` is usually used.

The following parameters are optional:

- `@kms_master_key_arn` – The ARN for the symmetric AWS KMS CMK to use to encrypt the item.
- You can't use the default encryption key. If you use the default key, the database won't be backed up.
- If you don't specify a AWS KMS key identifier, the backup file won't be encrypted. For more information, see [Encrypting Amazon RDS resources](#).
- When you specify a AWS KMS CMK, client-side encryption is used.
- Amazon RDS doesn't support asymmetric CMKs. For more information, see [Using symmetric and asymmetric keys in the AWS Key Management Service Developer Guide](#).
- `@overwrite_s3_backup_file` – A value that indicates whether to overwrite an existing backup file.
 - 0 – Doesn't overwrite an existing file. This value is the default.

Setting `@overwrite_s3_backup_file` to 0 returns an error if the file already exists.

- 1 – Overwrites an existing file that has the specified name, even if it isn't a backup file.
- `@type` – The type of backup.
 - `DIFFERENTIAL` – Makes a differential backup.
 - `FULL` – Makes a full backup. This value is the default.

A differential backup is based on the last full backup. For differential backups to work, you can't take a snapshot between the last full backup and the differential backup. If you want a differential backup, but a snapshot exists, then do another full backup before proceeding with the differential backup.

You can look for the last full backup or snapshot using the following example SQL query:

```
select top 1
    database_name
    , backup_start_date
    , backup_finish_date
from msdb.dbo.backupset
where database_name = 'mydatabase'
and type = 'D'
order by backup_start_date desc;
```

- `@number_of_files` – The number of files into which the backup will be divided (chunked). The maximum number is 10.
 - Multifile backup is supported for both full and differential backups.
 - If you enter a value of 1 or omit the parameter, a single backup file is created.

Provide the prefix that the files have in common, then suffix that with an asterisk (*). The asterisk can be anywhere in the `file_name` part of the S3 ARN. The asterisk is replaced by a series of alphanumeric strings in the generated files, starting with 1-of-`number_of_files`.

For example, if the file names in the S3 ARN are `backup*.bak` and you set `@number_of_files=4`, the backup files generated are `backup1-of-4.bak`, `backup2-of-4.bak`, `backup3-of-4.bak`, and `backup4-of-4.bak`.

- If any of the file names already exists, and `@overwrite_s3_backup_file` is 0, an error is returned.

- Multifile backups can only have one asterisk in the *file_name* part of the S3 ARN.
- Single-file backups can have any number of asterisks in the *file_name* part of the S3 ARN.
Asterisks aren't removed from the generated file name.

Examples

Example of differential backup

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup1.bak',
@overwrite_s3_backup_file=1,
@type='DIFFERENTIAL';
```

Example of full backup with encryption

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup1.bak',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE',
@overwrite_s3_backup_file=1,
@type='FULL';
```

Example of multifile backup

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@number_of_files=4;
```

Example of multifile differential backup

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@type='DIFFERENTIAL',
@number_of_files=4;
```

Example of multifile backup with encryption

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE',
@number_of_files=4;
```

Example of multifile backup with S3 overwrite

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@overwrite_s3_backup_file=1,
@number_of_files=4;
```

Example of single-file backup with the @number_of_files parameter

This example generates a backup file named `backup*.bak`.

```
exec msdb.dbo.rds_backup_database
@source_db_name='mydatabase',
@s3_arn_to_backup_to='arn:aws:s3:::mybucket/backup*.bak',
@number_of_files=1;
```

Restoring a database

To restore your database, call the `rds_restore_database` stored procedure. Amazon RDS creates an initial snapshot of the database after the restore task is complete and the database is open.

Usage

```
exec msdb.dbo.rds_restore_database
@restore_db_name='database_name',
@s3_arn_to_restore_from='arn:aws:s3:::bucket_name/file_name.extension',
@with_norecovery=0|1,
[@kms_master_key_arn='arn:aws:kms:region:account-id:key/key-id'],
[@type='DIFFERENTIAL|FULL'];
```

The following parameters are required:

- `@restore_db_name` – The name of the database to restore.
- `@s3_arn_to_restore_from` – The ARN indicating the Amazon S3 prefix and names of the backup files used to restore the database.
 - For a single-file backup, provide the entire file name.
 - For a multifile backup, provide the prefix that the files have in common, then suffix that with an asterisk (*).
 - If `@s3_arn_to_restore_from` is empty, the following error message is returned: S3 ARN prefix cannot be empty.

The following parameter is required for differential restores, but optional for full restores:

- `@with_norecovery` – The recovery clause to use for the restore operation.
 - Set it to 0 to restore with RECOVERY. In this case, the database is online after the restore.
 - Set it to 1 to restore with NORECOVERY. In this case, the database remains in the RESTORING state after restore task completion. With this approach, you can do later differential restores.
 - For DIFFERENTIAL restores, specify 0 or 1.
 - For FULL restores, this value defaults to 0.

The following parameters are optional:

- `@kms_master_key_arn` – If you encrypted the backup file, the AWS KMS customer master key (CMK) to use to decrypt the file.

When you specify a AWS KMS CMK, client-side encryption is used.
- `@type` – The type of restore. Valid types are DIFFERENTIAL and FULL. The default value is FULL.

Note

For differential restores, either the database must be in the RESTORING state or a task must already exist that restores with NORECOVERY.

You can't restore later differential backups while the database is online.
You can't submit a restore task for a database that already has a pending restore task with RECOVERY.
Full restores with NORECOVERY and differential restores aren't supported on Multi-AZ instances.
Restoring a database on a Multi-AZ instance with read replicas is similar to restoring a database on a Multi-AZ instance. You don't have to take any additional actions to restore a database on a replica.

Examples

Example of single-file restore

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak';
```

Example of multifile restore

To avoid errors when restoring multiple files, make sure that all the backup files have the same prefix, and that no other files use that prefix.

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup*';
```

Example of full database restore with RECOVERY

The following three examples perform the same task, full restore with RECOVERY.

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak';
```

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
[@type='DIFFERENTIAL | FULL'];
```

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='FULL',
@with_norecovery=0;
```

Example of full database restore with encryption

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE';
```

Example of full database restore with NORECOVERY

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
```

```
@type='FULL',
@with_norecovery=1;
```

Example of differential restore with NORECOVERY

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='DIFFERENTIAL',
@with_norecovery=1;
```

Example of differential restore with RECOVERY

```
exec msdb.dbo.rds_restore_database
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/backup1.bak',
@type='DIFFERENTIAL',
@with_norecovery=0;
```

Restoring a log

To restore your log, call the `rds_restore_log` stored procedure.

Usage

```
exec msdb.dbo.rds_restore_log
@restore_db_name='database_name',
@s3_arn_to_restore_from='arn:aws:s3:::bucket_name/log_file_name.extension',
[@kms_master_key_arn='arn:aws:kms:region:account-id:key/key-id'],
[@with_norecovery=0|1],
[@stopat='datetime'];
```

The following parameters are required:

- `@restore_db_name` – The name of the database whose log to restore.
- `@s3_arn_to_restore_from` – The ARN indicating the Amazon S3 prefix and name of the log file used to restore the log. The file can have any extension, but `.trn` is usually used.

If `@s3_arn_to_restore_from` is empty, the following error message is returned: S3 ARN prefix cannot be empty.

The following parameters are optional:

- `@kms_master_key_arn` – If you encrypted the log, the AWS KMS customer master key (CMK) to use to decrypt the log.
- `@with_norecovery` – The recovery clause to use for the restore operation. This value defaults to 1.
 - Set it to 0 to restore with RECOVERY. In this case, the database is online after the restore. You can't restore further log backups while the database is online.
 - Set it to 1 to restore with NORECOVERY. In this case, the database remains in the RESTORING state after restore task completion. With this approach, you can do later log restores.
- `@stopat` – A value that specifies that the database is restored to its state at the date and time specified (in datetime format). Only transaction log records written before the specified date and time are applied to the database.

If this parameter isn't specified (it is NULL), the complete log is restored.

Note

For log restores, either the database must be in a state of restoring or a task must already exist that restores with NORECOVERY.

You can't restore log backups while the database is online.

You can't submit a log restore task on a database that already has a pending restore task with RECOVERY.

Log restores aren't supported on Multi-AZ instances.

Examples

Example of log restore

```
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn';
```

Example of log restore with encryption

```
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@kms_master_key_arn='arn:aws:kms:us-east-1:123456789012:key/AKIAIOSFODNN7EXAMPLE';
```

Example of log restore with NORECOVERY

The following two examples perform the same task, log restore with NORECOVERY.

```
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@with_norecovery=1;
```

```
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn';
```

Example of log restore with RECOVERY

```
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@with_norecovery=0;
```

Example of log restore with STOPAT clause

```
exec msdb.dbo.rds_restore_log
@restore_db_name='mydatabase',
@s3_arn_to_restore_from='arn:aws:s3:::mybucket/mylog.trn',
@with_norecovery=0,
@stopat='2019-12-01 03:57:09';
```

Finishing a database restore

If the last restore task on the database was performed using @with_norecovery=1, the database is now in the RESTORING state. Open this database for normal operation by using the rds_finish_restore stored procedure.

Usage

```
exec msdb.dbo.rds_finish_restore @db_name='database_name';
```

Note

To use this approach, the database must be in the RESTORING state without any pending restore tasks.

The `rds_finish_restore` procedure isn't supported on Multi-AZ instances.

To finish restoring the database, use the master login. Or use the user login that most recently restored the database or log with NORECOVERY.

Working with partially restored databases

Dropping a partially restored database

To drop a partially restored database (left in the RESTORING state), use the `rds_drop_database` stored procedure.

```
exec msdb.dbo.rds_drop_database @db_name='database_name';
```

Note

You can't submit a DROP database request for a database that already has a pending restore or finish restore task.

To drop the database, use the master login. Or use the user login that most recently restored the database or log with NORECOVERY.

Snapshot restore and point-in-time recovery behavior for partially restored databases

Partially restored databases in the source instance (left in the RESTORING state) are dropped from the target instance during snapshot restore and point-in-time recovery.

Cancelling a task

To cancel a backup or restore task, call the `rds_cancel_task` stored procedure.

Note

You can't cancel a FINISH_RESTORE task.

Usage

```
exec msdb.dbo.rds_cancel_task @task_id=ID_number;
```

The following parameter is required:

- `@task_id` – The ID of the task to cancel. You can get the task ID by calling `rds_task_status`.

Tracking the status of tasks

To track the status of your backup and restore tasks, call the `rds_task_status` stored procedure. If you don't provide any parameters, the stored procedure returns the status of all tasks. The status for tasks is updated approximately every two minutes. Task history is retained for 36 days.

Usage

```
exec msdb.dbo.rds_task_status
```

```
[@db_name='database_name'],
[@task_id=ID_number];
```

The following parameters are optional:

- @db_name – The name of the database to show the task status for.
- @task_id – The ID of the task to show the task status for.

Examples

Example of listing the status for a specific task

```
exec msdb.dbo.rds_task_status @task_id=5;
```

Example of listing the status for a specific database and task

```
exec msdb.dbo.rds_task_status
@db_name='my_database',
@task_id=5;
```

Example of listing all tasks and their statuses on a specific database

```
exec msdb.dbo.rds_task_status @db_name='my_database';
```

Example of listing all tasks and their statuses on the current instance

```
exec msdb.dbo.rds_task_status;
```

Response

The `rds_task_status` stored procedure returns the following columns.

Column	Description
<code>task_id</code>	The ID of the task.
<code>task_type</code>	Task type depending on the input parameters, as follows: <ul style="list-style-type: none">• For backup tasks:<ul style="list-style-type: none">• BACKUP_DB – Full database backup• BACKUP_DB_DIFFERENTIAL – Differential database backup• For restore tasks:<ul style="list-style-type: none">• RESTORE_DB – Full database restore with RECOVERY• RESTORE_DB_NORECOVERY – Full database restore with NORECOVERY• RESTORE_DB_DIFFERENTIAL – Differential database restore with RECOVERY• RESTORE_DB_DIFFERENTIAL_NORECOVERY – Differential database restore with NORECOVERY• RESTORE_DB_LOG – Log restore with RECOVERY• RESTORE_DB_LOG_NORECOVERY – Log restore with NORECOVERY• For tasks that finish a restore:<ul style="list-style-type: none">• FINISH_RESTORE – Finish restore and open database

Column	Description
	<p>Amazon RDS creates an initial snapshot of the database after it is open on completion of the following restore tasks:</p> <ul style="list-style-type: none"> • RESTORE_DB • RESTORE_DB_DIFFERENTIAL • RESTORE_DB_LOG • FINISH_RESTORE
database_name	The name of the database that the task is associated with.
% complete	The progress of the task as a percent value.
duration (mins)	The amount of time spent on the task, in minutes.
lifecycle	<p>The status of the task. The possible statuses are the following:</p> <ul style="list-style-type: none"> • CREATED – As soon as you call <code>rds_backup_database</code> or <code>rds_restore_database</code>, a task is created and the status is set to <code>CREATED</code>. • IN_PROGRESS – After a backup or restore task starts, the status is set to <code>IN_PROGRESS</code>. It can take up to 5 minutes for the status to change from <code>CREATED</code> to <code>IN_PROGRESS</code>. • SUCCESS – After a backup or restore task completes, the status is set to <code>SUCCESS</code>. • ERROR – If a backup or restore task fails, the status is set to <code>ERROR</code>. For more information about the error, see the <code>task_info</code> column. • CANCEL_REQUESTED – As soon as you call <code>rds_cancel_task</code>, the status of the task is set to <code>CANCEL_REQUESTED</code>. • CANCELLED – After a task is successfully canceled, the status of the task is set to <code>CANCELLED</code>.
task_info	<p>Additional information about the task.</p> <p>If an error occurs while backing up or restoring a database, this column contains information about the error. For a list of possible errors, and mitigation strategies, see Troubleshooting (p. 685).</p>
last_updated	The date and time that the task status was last updated. The status is updated after every 5 percent of progress.
created_at	The date and time that the task was created.
S3_object_arn	The ARN indicating the Amazon S3 prefix and the name of the file that is being backed up or restored.
overwrite_s3_backup_file	The value of the <code>@overwrite_s3_backup_file</code> parameter specified when calling a backup task. For more information, see Backing up a database (p. 675) .
KMS_master_key_arn	The ARN for the AWS KMS CMK used for encryption (for backup) and decryption (for restore).
filepath	Not applicable to native backup and restore tasks.
overwrite_file	Not applicable to native backup and restore tasks.

Compressing backup files

To save space in your Amazon S3 bucket, you can compress your backup files. For more information about compressing backup files, see [Backup compression](#) in the Microsoft documentation.

Compressing your backup files is supported for the following database editions:

- Microsoft SQL Server Enterprise Edition
- Microsoft SQL Server Standard Edition

To turn on compression for your backup files, run the following code:

```
exec rdsadmin..rds_set_configuration 'S3 backup compression', 'true';
```

To turn off compression for your backup files, run the following code:

```
exec rdsadmin..rds_set_configuration 'S3 backup compression', 'false';
```

Troubleshooting

The following are issues you might encounter when you use native backup and restore.

Issue	Troubleshooting suggestions
Access Denied	<p>The backup or restore process can't access the backup file. This is usually caused by issues like the following:</p> <ul style="list-style-type: none">• Referencing the incorrect bucket. Referencing the bucket using an incorrect format. Referencing a file name without using the ARN.• Incorrect permissions on the bucket file. For example, if it is created by a different account that is trying to access it now, add the correct permissions.• An IAM policy that is incorrect or incomplete. Your IAM role must include all the necessary elements, including, for example, the correct version. These are highlighted in Importing and exporting SQL Server databases (p. 671).
BACKUP DATABASE WITH COMPRESSION isn't supported on <edition_name> Edition	<p>Compressing your backup files is only supported for Microsoft SQL Server Enterprise Edition and Standard Edition.</p> <p>For more information, see Compressing backup files (p. 685).</p>
Key <ARN> does not exist	<p>You attempted to restore an encrypted backup, but didn't provide a valid encryption key. Check your encryption key and retry.</p> <p>For more information, see Restoring a database (p. 678).</p>
Please reissue task with correct type and overwrite property	<p>If you attempt to back up your database and provide the name of a file that already exists, but set the overwrite property to false, the save operation fails. To fix this error, either provide the name of a file that doesn't already exist, or set the overwrite property to true.</p> <p>For more information, see Backing up a database (p. 675).</p>

Issue	Troubleshooting suggestions

Importing and exporting SQL Server data using other methods

Following, you can find information about using snapshots to import your Microsoft SQL Server data to Amazon RDS. You can also find information about using snapshots to export your data from an RDS DB instance running SQL Server.

If your scenario supports it, it's easier to move data in and out of Amazon RDS by using the native backup and restore functionality. For more information, see [Importing and exporting SQL Server databases \(p. 671\)](#).

Note

Amazon RDS for Microsoft SQL Server does not support importing data into the `msdb` database.

Importing data into SQL Server on Amazon RDS by using a snapshot

To import data into a SQL Server DB instance by using a snapshot

1. Create a DB instance. For more information, see [Creating an Amazon RDS DB instance \(p. 141\)](#).
2. Stop applications from accessing the destination DB instance.

If you prevent access to your DB instance while you are importing data, data transfer is faster. Additionally, you don't need to worry about conflicts while data is being loaded if other applications cannot write to the DB instance at the same time. If something goes wrong and you have to roll back to an earlier database snapshot, the only changes that you lose are the imported data. You can import this data again after you resolve the issue.

For information about controlling access to your DB instance, see [Working with DB security groups \(EC2-Classic platform\) \(p. 1704\)](#).

3. Create a snapshot of the target database.

If the target database is already populated with data, we recommend that you take a snapshot of the database before you import the data. If something goes wrong with the data import or you want to discard the changes, you can restore the database to its previous state by using the snapshot. For information about database snapshots, see [Creating a DB snapshot \(p. 346\)](#).

Note

When you take a database snapshot, I/O operations to the database are suspended for a moment (milliseconds) while the backup is in progress.

4. Disable automated backups on the target database.

Disabling automated backups on the target DB instance improves performance while you are importing your data because Amazon RDS doesn't log transactions when automatic backups are disabled. However, there are some things to consider. Automated backups are required to perform a point-in-time recovery. Thus, you can't restore the database to a specific point in time while you are importing data. Additionally, any automated backups that were created on the DB instance are erased unless you choose to retain them.

Choosing to retain the automated backups can help protect you against accidental deletion of data. Amazon RDS also saves the database instance properties along with each automated backup to make it easy to recover. Using this option lets you can restore a deleted database instance to a specified point in time within the backup retention period even after deleting it. Automated backups are automatically deleted at the end of the specified backup window, just as they are for an active database instance.

You can also use previous snapshots to recover the database, and any snapshots that you have taken remain available. For information about automated backups, see [Working with backups \(p. 328\)](#).

5. Disable foreign key constraints, if applicable.

If you need to disable foreign key constraints, you can do so with the following script.

```
--Disable foreign keys on all tables
DECLARE @table_name SYSNAME;
DECLARE @cmd NVARCHAR(MAX);
DECLARE table_cursor CURSOR FOR SELECT name FROM sys.tables;

OPEN table_cursor;
FETCH NEXT FROM table_cursor INTO @table_name;

WHILE @@FETCH_STATUS = 0 BEGIN
    SELECT @cmd = 'ALTER TABLE '+QUOTENAME(@table_name)+' NOCHECK CONSTRAINT ALL';
    EXEC (@cmd);
    FETCH NEXT FROM table_cursor INTO @table_name;
END

CLOSE table_cursor;
DEALLOCATE table_cursor;

GO
```

6. Drop indexes, if applicable.
7. Disable triggers, if applicable.

If you need to disable triggers, you can do so with the following script.

```
--Disable triggers on all tables
DECLARE @enable BIT = 0;
DECLARE @trigger SYSNAME;
DECLARE @table SYSNAME;
DECLARE @cmd NVARCHAR(MAX);
DECLARE trigger_cursor CURSOR FOR SELECT trigger_object.name trigger_name,
    table_object.name table_name
FROM sysobjects trigger_object
JOIN sysobjects table_object ON trigger_object.parent_obj = table_object.id
WHERE trigger_object.type = 'TR';

OPEN trigger_cursor;
FETCH NEXT FROM trigger_cursor INTO @trigger, @table;

WHILE @@FETCH_STATUS = 0 BEGIN
    IF @enable = 1
        SET @cmd = 'ENABLE ';
    ELSE
        SET @cmd = 'DISABLE ';

    SET @cmd = @cmd + ' TRIGGER dbo.'+QUOTENAME(@trigger)+'' ON
dbo.'+QUOTENAME(@table)+'' ;
    EXEC (@cmd);
    FETCH NEXT FROM trigger_cursor INTO @trigger, @table;
END

CLOSE trigger_cursor;
DEALLOCATE trigger_cursor;

GO
```

8. Query the source SQL Server instance for any logins that you want to import to the destination DB instance.

SQL Server stores logins and passwords in the `master` database. Because Amazon RDS doesn't grant access to the `master` database, you cannot directly import logins and passwords into your destination DB instance. Instead, you must query the `master` database on the source SQL Server instance to generate a data definition language (DDL) file. This file should include all logins and passwords that you want to add to the destination DB instance. This file also should include role memberships and permissions that you want to transfer.

For information about querying the `master` database, see [How to transfer the logins and the passwords between instances of SQL Server 2005 and SQL Server 2008](#) in the Microsoft Knowledge Base.

The output of the script is another script that you can run on the destination DB instance. The script in the Knowledge Base article has the following code:

```
p.type IN
```

Every place `p.type` appears, use the following code instead:

```
p.type = 'S'
```

9. Import the data using the method in [Import the data \(p. 690\)](#).
10. Grant applications access to the target DB instance.

When your data import is complete, you can grant access to the DB instance to those applications that you blocked during the import. For information about controlling access to your DB instance, see [Working with DB security groups \(EC2-Classic platform\) \(p. 1704\)](#).

11. Enable automated backups on the target DB instance.

For information about automated backups, see [Working with backups \(p. 328\)](#).

12. Enable foreign key constraints.

If you disabled foreign key constraints earlier, you can now enable them with the following script.

```
--Enable foreign keys on all tables
DECLARE @table_name SYSNAME;
DECLARE @cmd NVARCHAR(MAX);
DECLARE table_cursor CURSOR FOR SELECT name FROM sys.tables;

OPEN table_cursor;
FETCH NEXT FROM table_cursor INTO @table_name;

WHILE @@FETCH_STATUS = 0 BEGIN
    SELECT @cmd = 'ALTER TABLE '+QUOTENAME(@table_name)+' CHECK CONSTRAINT ALL';
    EXEC (@cmd);
    FETCH NEXT FROM table_cursor INTO @table_name;
END

CLOSE table_cursor;
DEALLOCATE table_cursor;
```

13. Enable indexes, if applicable.
14. Enable triggers, if applicable.

If you disabled triggers earlier, you can now enable them with the following script.

```
--Enable triggers on all tables
DECLARE @enable BIT = 1;
DECLARE @trigger SYSNAME;
DECLARE @table SYSNAME;
DECLARE @cmd NVARCHAR(MAX);
DECLARE trigger_cursor CURSOR FOR SELECT trigger_object.name trigger_name,
    table_object.name table_name
FROM sysobjects trigger_object
JOIN sysobjects table_object ON trigger_object.parent_obj = table_object.id
WHERE trigger_object.type = 'TR';

OPEN trigger_cursor;
FETCH NEXT FROM trigger_cursor INTO @trigger, @table;

WHILE @@FETCH_STATUS = 0 BEGIN
    IF @enable = 1
        SET @cmd = 'ENABLE ';
    ELSE
        SET @cmd = 'DISABLE ';

    SET @cmd = @cmd + ' TRIGGER dbo.'+QUOTENAME(@trigger)+' ON
dbo.'+QUOTENAME(@table)+';
    EXEC (@cmd);
    FETCH NEXT FROM trigger_cursor INTO @trigger, @table;
END

CLOSE trigger_cursor;
DEALLOCATE trigger_cursor;
```

Import the data

Microsoft SQL Server Management Studio is a graphical SQL Server client that is included in all Microsoft SQL Server editions except the Express Edition. SQL Server Management Studio Express is available from Microsoft as a free download. To find this download, see [the Microsoft website](#).

Note

SQL Server Management Studio is available only as a Windows-based application.

SQL Server Management Studio includes the following tools, which are useful in importing data to a SQL Server DB instance:

- Generate and Publish Scripts Wizard
- Import and Export Wizard
- Bulk copy

Generate and Publish Scripts Wizard

The Generate and Publish Scripts Wizard creates a script that contains the schema of a database, the data itself, or both. You can generate a script for a database in your local SQL Server deployment. You can then run the script to transfer the information that it contains to an Amazon RDS DB instance.

Note

For databases of 1 GiB or larger, it's more efficient to script only the database schema. You then use the Import and Export Wizard or the bulk copy feature of SQL Server to transfer the data.

For detailed information about the Generate and Publish Scripts Wizard, see the [Microsoft SQL Server documentation](#).

In the wizard, pay particular attention to the advanced options on the **Set Scripting Options** page to ensure that everything you want your script to include is selected. For example, by default, database triggers are not included in the script.

When the script is generated and saved, you can use SQL Server Management Studio to connect to your DB instance and then run the script.

Import and Export Wizard

The Import and Export Wizard creates a special Integration Services package, which you can use to copy data from your local SQL Server database to the destination DB instance. The wizard can filter which tables and even which tuples within a table are copied to the destination DB instance.

Note

The Import and Export Wizard works well for large datasets, but it might not be the fastest way to remotely export data from your local deployment. For an even faster way, consider the SQL Server bulk copy feature.

For detailed information about the Import and Export Wizard, see the [Microsoft SQL Server documentation](#).

In the wizard, on the **Choose a Destination** page, do the following:

- For **Server Name**, type the name of the endpoint for your DB instance.
- For the server authentication mode, choose **Use SQL Server Authentication**.
- For **User name** and **Password**, type the credentials for the master user that you created for the DB instance.

Bulk copy

The SQL Server bulk copy feature is an efficient means of copying data from a source database to your DB instance. Bulk copy writes the data that you specify to a data file, such as an ASCII file. You can then run bulk copy again to write the contents of the file to the destination DB instance.

This section uses the **bcp** utility, which is included with all editions of SQL Server. For detailed information about bulk import and export operations, see [the Microsoft SQL Server documentation](#).

Note

Before you use bulk copy, you must first import your database schema to the destination DB instance. The Generate and Publish Scripts Wizard, described earlier in this topic, is an excellent tool for this purpose.

The following command connects to the local SQL Server instance. It generates a tab-delimited file of a specified table in the C:\ root directory of your existing SQL Server deployment. The table is specified by its fully qualified name, and the text file has the same name as the table that is being copied.

```
bcp dbname.schema_name.table_name out C:\table_name.txt -n -S localhost -U username -P password -b 10000
```

The preceding code includes the following options:

- **-n** specifies that the bulk copy uses the native data types of the data to be copied.
- **-S** specifies the SQL Server instance that the *bcp* utility connects to.
- **-U** specifies the user name of the account to log in to the SQL Server instance.
- **-P** specifies the password for the user specified by **-U**.

- **-b** specifies the number of rows per batch of imported data.

Note

There might be other parameters that are important to your import situation. For example, you might need the **-E** parameter that pertains to identity values. For more information; see the full description of the command line syntax for the **bcp** utility in the [Microsoft SQL Server documentation](#).

For example, suppose that a database named **store** that uses the default schema, **dbo**, contains a table named **customers**. The user account **admin**, with the password **insecure**, copies 10,000 rows of the **customers** table to a file named **customers.txt**.

```
bcp store.dbo.customers out C:\customers.txt -n -S localhost -U admin -P insecure -b 10000
```

After you generate the data file, you can upload the data to your DB instance by using a similar command. Beforehand, create the database and schema on the target DB instance. Then use the **in** argument to specify an input file instead of **out** to specify an output file. Instead of using **localhost** to specify the local SQL Server instance, specify the endpoint of your DB instance. If you use a port other than 1433, specify that too. The user name and password are the master user and password for your DB instance. The syntax is as follows.

```
bcp dbname.schema_name.table_name in C:\table_name.txt -n -S endpoint,port -  
U master_user_name -P master_user_password -b 10000
```

To continue the previous example, suppose that the master user name is **admin**, and the password is **insecure**. The endpoint for the DB instance is **rds.ckz2kqd4qsn1.us-east-1.rds.amazonaws.com**, and you use port 4080. The command is as follows.

```
bcp store.dbo.customers in C:\customers.txt -n -S rds.ckz2kqd4qsn1.us-east-1.rds.amazonaws.com,4080 -U admin -P insecure -b 10000
```

Exporting data from SQL Server on Amazon RDS

You can choose one of the following options to export data from an RDS for SQL Server DB instance:

- **Native database backup using a full backup file (.bak)** – Using .bak files to backup databases is heavily optimized, and is usually the fastest way to export data. For more information, see [Importing and exporting SQL Server databases \(p. 671\)](#).
- **SQL Server Import and Export Wizard** – For more information, see [SQL Server Import and Export Wizard \(p. 692\)](#).
- **SQL Server Generate and Publish Scripts Wizard and bcp utility** – For more information, see [SQL Server Generate and Publish Scripts Wizard and bcp utility \(p. 694\)](#).

SQL Server Import and Export Wizard

You can use the SQL Server Import and Export Wizard to copy one or more tables, views, or queries from your RDS for SQL Server DB instance to another data store. This choice is best if the target data store is not SQL Server. For more information, see [SQL Server Import and Export Wizard](#) in the SQL Server documentation.

The SQL Server Import and Export Wizard is available as part of Microsoft SQL Server Management Studio. This graphical SQL Server client is included in all Microsoft SQL Server editions except the Express Edition. SQL Server Management Studio is available only as a Windows-based application.

SQL Server Management Studio Express is available from Microsoft as a free download. To find this download, see [the Microsoft website](#).

To use the SQL Server Import and Export Wizard to export data

1. In SQL Server Management Studio, connect to your RDS for SQL Server DB instance. For details on how to do this, see [Connecting to a DB instance running the Microsoft SQL Server database engine \(p. 656\)](#).
2. In **Object Explorer**, expand **Databases**, open the context (right-click) menu for the source database, choose **Tasks**, and then choose **Export Data**. The wizard appears.
3. On the **Choose a Data Source** page, do the following:
 - a. For **Data source**, choose **SQL Server Native Client 11.0**.
 - b. Verify that the **Server name** box shows the endpoint of your RDS for SQL Server DB instance.
 - c. Select **Use SQL Server Authentication**. For **User name** and **Password**, type the master user name and password of your DB instance.
 - d. Verify that the **Database** box shows the database from which you want to export data.
 - e. Choose **Next**.
4. On the **Choose a Destination** page, do the following:
 - a. For **Destination**, choose **SQL Server Native Client 11.0**.

Note

Other target data sources are available. These include .NET Framework data providers, OLE DB providers, SQL Server Native Client providers, ADO.NET providers, Microsoft Office Excel, Microsoft Office Access, and the Flat File source. If you choose to target one of these data sources, skip the remainder of step 4. For details on the connection information to provide next, see [Choose a destination](#) in the SQL Server documentation.

- b. For **Server name**, type the server name of the target SQL Server DB instance.
- c. Choose the appropriate authentication type. Type a user name and password if necessary.
- d. For **Database**, choose the name of the target database, or choose **New** to create a new database to contain the exported data.

If you choose **New**, see [Create database](#) in the SQL Server documentation for details on the database information to provide.

- e. Choose **Next**.
5. On the **Table Copy or Query** page, choose **Copy data from one or more tables or views** or **Write a query to specify the data to transfer**. Choose **Next**.
6. If you chose **Write a query to specify the data to transfer**, you see the **Provide a Source Query** page. Type or paste in a SQL query, and then choose **Parse** to verify it. Once the query validates, choose **Next**.
7. On the **Select Source Tables and Views** page, do the following:
 - a. Select the tables and views that you want to export, or verify that the query you provided is selected.
 - b. Choose **Edit Mappings** and specify database and column mapping information. For more information, see [Column mappings](#) in the SQL Server documentation.
 - c. (Optional) To see a preview of data to be exported, select the table, view, or query, and then choose **Preview**.
 - d. Choose **Next**.
8. On the **Run Package** page, verify that **Run immediately** is selected. Choose **Next**.
9. On the **Complete the Wizard** page, verify that the data export details are as you expect. Choose **Finish**.

10. On the **The execution was successful** page, choose **Close**.

SQL Server Generate and Publish Scripts Wizard and bcp utility

You can use the SQL Server Generate and Publish Scripts Wizard to create scripts for an entire database or just selected objects. You can run these scripts on a target SQL Server DB instance to recreate the scripted objects. You can then use the bcp utility to bulk export the data for the selected objects to the target DB instance. This choice is best if you want to move a whole database (including objects other than tables) or large quantities of data between two SQL Server DB instances. For a full description of the bcp command-line syntax, see [bcp utility](#) in the Microsoft SQL Server documentation.

The SQL Server Generate and Publish Scripts Wizard is available as part of Microsoft SQL Server Management Studio. This graphical SQL Server client is included in all Microsoft SQL Server editions except the Express Edition. SQL Server Management Studio is available only as a Windows-based application. SQL Server Management Studio Express is available from Microsoft as a [free download](#).

To use the SQL Server Generate and Publish Scripts Wizard and the bcp utility to export data

1. In SQL Server Management Studio, connect to your RDS for SQL Server DB instance. For details on how to do this, see [Connecting to a DB instance running the Microsoft SQL Server database engine \(p. 656\)](#).
2. In **Object Explorer**, expand the **Databases** node and select the database you want to script.
3. Follow the instructions in [Generate and publish scripts Wizard](#) in the SQL Server documentation to create a script file.
4. In SQL Server Management Studio, connect to your target SQL Server DB instance.
5. With the target SQL Server DB instance selected in **Object Explorer**, choose **Open** on the **File** menu, choose **File**, and then open the script file.
6. If you have scripted the entire database, review the CREATE DATABASE statement in the script. Make sure that the database is being created in the location and with the parameters that you want. For more information, see [CREATE DATABASE](#) in the SQL Server documentation.
7. If you are creating database users in the script, check to see if server logins exist on the target DB instance for those users. If not, create logins for those users; the scripted commands to create the database users fail otherwise. For more information, see [Create a login](#) in the SQL Server documentation.
8. Choose **!Execute** on the SQL Editor menu to run the script file and create the database objects. When the script finishes, verify that all database objects exist as expected.
9. Use the bcp utility to export data from the RDS for SQL Server DB instance into files. Open a command prompt and type the following command.

```
bcp database_name.schema_name.table_name out data_file -n -S aws_rds_sql_endpoint -U
username -P password
```

The preceding code includes the following options:

- *table_name* is the name of one of the tables that you've recreated in the target database and now want to populate with data.
- *data_file* is the full path and name of the data file to be created.
- *-n* specifies that the bulk copy uses the native data types of the data to be copied.
- *-S* specifies the SQL Server DB instance to export from.
- *-U* specifies the user name to use when connecting to the SQL Server DB instance.
- *-P* specifies the password for the user specified by *-U*.

The following shows an example command.

```
bcp world.dbo.city out C:\Users\JohnDoe\city.dat -n -S sql-jdoe.1234abcd.us-west-2.rds.amazonaws.com,1433 -U JohnDoe -P ClearTextPassword
```

Repeat this step until you have data files for all of the tables you want to export.

10. Prepare your target DB instance for bulk import of data by following the instructions at [Basic guidelines for bulk importing data](#) in the SQL Server documentation.
11. Decide on a bulk import method to use after considering performance and other concerns discussed in [About bulk import and bulk export operations](#) in the SQL Server documentation.
12. Bulk import the data from the data files that you created using the bcp utility. To do so, follow the instructions at either [Import and export bulk data by using the bcp utility](#) or [Import bulk data by using BULK INSERT or OPENROWSET\(BULK...\)](#) in the SQL Server documentation, depending on what you decided in step 11.

Working with read replicas for Microsoft SQL Server in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see [Working with read replicas \(p. 278\)](#).

In this section, you can find specific information about working with read replicas on Amazon RDS for SQL Server.

Topics

- [Configuring read replicas for SQL Server \(p. 696\)](#)
- [Read replica limitations with SQL Server \(p. 696\)](#)
- [Troubleshooting a SQL Server read replica problem \(p. 697\)](#)

Configuring read replicas for SQL Server

Before a DB instance can serve as a source instance for replication, you must enable automatic backups on the source DB instance. To do so, you set the backup retention period to a value other than 0. The source DB instance must be a Multi-AZ deployment with Always On Availability Groups (AGs). Setting this type of deployment also enforces that automatic backups are enabled.

Creating a SQL Server read replica doesn't require an outage for the primary DB instance. Amazon RDS sets the necessary parameters and permissions for the source DB instance and the read replica without any service interruption. A snapshot is taken of the source DB instance, and this snapshot becomes the read replica. No outage occurs when you delete a read replica.

You can create up to five read replicas from one source DB instance. For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

The SQL Server DB engine version of the source DB instance and all of its read replicas must be the same. Amazon RDS upgrades the primary immediately after upgrading the read replicas, regardless of the maintenance window. For more information about upgrading the DB engine version, see [Upgrading the Microsoft SQL Server DB engine \(p. 666\)](#).

For a read replica to receive and apply changes from the source, it should have sufficient compute and storage resources. If a read replica reaches compute, network, or storage resource capacity, the read replica stops receiving or applying changes from its source. You can modify the storage and CPU resources of a read replica independently from its source and other read replicas.

Read replica limitations with SQL Server

The following limitations apply to SQL Server read replicas on Amazon RDS:

- Read replicas are only available on the SQL Server Enterprise Edition (EE) engine.
- Read replicas are available for SQL Server versions 2016–2019.
- The source DB instance to be replicated must be a Multi-AZ deployment with Always On AGs.
- Read replicas are only available for DB instances on the EC2-VPC platform.
- Read replicas are only available for DB instances running on DB instance classes with four or more vCPUs.
- The following aren't supported on Amazon RDS for SQL Server:
 - Creating a read replica in a different AWS Region (a cross-Region read replica)

- Backup retention of read replicas
- Point-in-time recovery from read replicas
- Manual snapshots of read replicas
- Multi-AZ read replicas
- Creating read replicas of read replicas
- Synchronization of user logins to read replicas
- Amazon RDS for SQL Server doesn't intervene to mitigate high replica lag between a source DB instance and its read replicas. Make sure that the source DB instance and its read replicas are sized properly, in terms of computing power and storage, to suit their operational load.
- A SQL Server read replica belongs to the same option group as the source DB instance. Modifications to the source option group or source option group membership propagate to read replicas. These changes are applied to the read replicas immediately after they are applied to the source DB instance, regardless of the read replica's maintenance window.

For more information about option groups, see [Working with option groups \(p. 212\)](#).

Troubleshooting a SQL Server read replica problem

You can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric. For information about replication lag time, see [Monitoring read replication \(p. 288\)](#).

If replication lag is too long, you can use the following query to get information about the lag.

```
SELECT AR.replica_server_name
      , DB_NAME(ARS.database_id) 'database_name'
      , AR.availability_mode_desc
      , ARS.synchronization_health_desc
      , ARS.last_hardened_lsn
      , ARS.last_redone_lsn
      , ARS.secondary_lag_seconds
  FROM sys.dm_hadr_database_replica_states ARS
 INNER JOIN sys.availability_replicas AR ON ARS.replica_id = AR.replica_id
--WHERE DB_NAME(ARS.database_id) = 'database_name'
 ORDER BY AR.replica_server_name;
```

Multi-AZ deployments for Microsoft SQL Server

Multi-AZ deployments provide increased availability, data durability, and fault tolerance for DB instances. In the event of planned database maintenance or unplanned service disruption, Amazon RDS automatically fails over to the up-to-date secondary DB instance. This functionality lets database operations resume quickly without manual intervention. The primary and standby instances use the same endpoint, whose physical network address transitions to the secondary replica as part of the failover process. You don't have to reconfigure your application when a failover occurs.

Amazon RDS supports Multi-AZ deployments for Microsoft SQL Server by using either SQL Server Database Mirroring (DBM) or Always On Availability Groups (AGs). Amazon RDS monitors and maintains the health of your Multi-AZ deployment. If problems occur, RDS automatically repairs unhealthy DB instances, reestablishes synchronization, and initiates failovers. Failover only occurs if the standby and primary are fully in sync. You don't have to manage anything.

When you set up SQL Server Multi-AZ, RDS automatically configures all databases on the instance to use DBM or AGs. Amazon RDS handles the primary, the witness, and the secondary DB instance for you. Because configuration is automatic, RDS selects DBM or Always On AGs based on the version of SQL Server that you deploy.

Amazon RDS supports Multi-AZ with Always On AGs for the following SQL Server versions and editions:

- SQL Server 2019: Standard and Enterprise Editions
- SQL Server 2017: Enterprise Edition 14.00.3049.1 or later
- SQL Server 2016: Enterprise Edition 13.00.5216.0 or later

Amazon RDS supports Multi-AZ with DBM for the following SQL Server versions and editions, except for the versions noted previously:

- SQL Server 2017: Standard and Enterprise Editions
- SQL Server 2016: Standard and Enterprise Editions
- SQL Server 2014: Standard and Enterprise Editions
- SQL Server 2012: Standard and Enterprise Editions

Amazon RDS supports Multi-AZ for SQL Server in all AWS Regions, with the following exceptions:

- Asia Pacific (Osaka): Neither DBM nor Always On AGs are supported here.
- Asia Pacific (Sydney): Supported for [DB instances in VPCs](#).
- Asia Pacific (Tokyo): Supported for [DB instances in VPCs](#).
- South America (São Paulo): Supported on all [DB instance classes](#) except m1 and m2.

You can use the following SQL query to determine whether your SQL Server DB instance is Single-AZ, Multi-AZ with DBM, or Multi-AZ with Always On AGs:

```
SELECT CASE WHEN dm.mirroring_state_desc IS NOT NULL THEN 'Multi-AZ (Mirroring)'
            WHEN dhdrs.group_database_id IS NOT NULL THEN 'Multi-AZ (AlwaysOn)'
            ELSE 'Single-AZ'
        END 'high_availability'
FROM sys.databases sd
LEFT JOIN sys.database_mirroring dm ON sd.database_id = dm.database_id
LEFT JOIN sys.dm_hadr_database_replica_states dhdrs ON sd.database_id = dhdrs.database_id
AND dhdrs.is_local = 1
WHERE DB_NAME(sd.database_id) = 'rdsadmin';
```

The output resembles the following:

```
high_availability  
Multi-AZ (Mirroring)
```

Adding Multi-AZ to a Microsoft SQL Server DB instance

When you create a new SQL Server DB instance using the AWS Management Console, you can add Multi-AZ with Database Mirroring (DBM) or Always On AGs. You do so by choosing **Yes (Mirroring / Always On)** from **Multi-AZ deployment**. For more information, see [Creating an Amazon RDS DB instance \(p. 141\)](#).

When you modify an existing SQL Server DB instance using the AWS Management Console, you can add Multi-AZ with DBM or AGs by choosing **Yes (Mirroring / Always On)** from **Multi-AZ deployment** on the **Modify DB instance** page. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

Note

If your DB instance is running Database Mirroring (DBM)—not Always On Availability Groups (AGs)—you might need to disable in-memory optimization before you add Multi-AZ. Disable in-memory optimization with DBM before you add Multi-AZ if your DB instance runs SQL Server 2014, 2016, or 2017 Enterprise Edition and has in-memory optimization enabled.

If your DB instance is running AGs, it doesn't require this step.

Microsoft SQL Server Multi-AZ deployment notes and recommendations

The following are some restrictions when working with Multi-AZ deployments for Microsoft SQL Server DB instances:

- Cross-Region Multi-AZ isn't supported.
- You can't configure the secondary DB instance to accept database read activity.
- Multi-AZ with Always On Availability Groups (AGs) supports in-memory optimization.
- Multi-AZ with Always On Availability Groups (AGs) doesn't support Kerberos authentication for the availability group listener. This is because the listener has no Service Principal Name (SPN).
- You can't rename a database on a SQL Server DB instance that is in a SQL Server Multi-AZ deployment. If you need to rename a database on such an instance, first turn off Multi-AZ for the DB instance, then rename the database. Finally, turn Multi-AZ back on for the DB instance.
- You can only restore Multi-AZ DB instances that are backed up using the full recovery model.

The following are some notes about working with Multi-AZ deployments for Microsoft SQL Server DB instances:

- Amazon RDS exposes the Always On AGs **availability group listener endpoint**. The endpoint is visible in the console, and is returned by the `DescribeDBInstances` API as an entry in the endpoints field.
- Amazon RDS supports **availability group multisubnet failovers**.
- To use SQL Server Multi-AZ with a SQL Server DB instance in a VPC, first create a DB subnet group that has subnets in at least two distinct Availability Zones. Then assign the DB subnet group to the primary replica of the SQL Server DB instance.
- When a DB instance is modified to be a Multi-AZ deployment, during the modification it has a status of **modifying**. Amazon RDS creates the standby, and makes a backup of the primary DB instance. After the process is complete, the status of the primary DB instance becomes **available**.

- Multi-AZ deployments maintain all databases on the same node. If a database on the primary host fails over, all your SQL Server databases fail over as one atomic unit to your standby host. Amazon RDS provisions a new healthy host, and replaces the unhealthy host.
- Multi-AZ with DBM or AGs supports a single standby replica.
- Users, logins, and permissions are automatically replicated for you on the secondary. You don't need to recreate them. User-defined server roles (a SQL Server 2012 feature) are only replicated in Multi-AZ instances for AGs instances.
- If you have SQL Server Agent jobs, recreate them on the secondary. You do so because these jobs are stored in the msdb database, and you can't replicate this database by using Database Mirroring (DBM) or Always On Availability Groups (AGs). Create the jobs first in the original primary, then fail over, and create the same jobs in the new primary.
- You might observe elevated latencies compared to a standard DB instance deployment (in a single Availability Zone) because of the synchronous data replication.
- Failover times are affected by the time it takes to complete the recovery process. Large transactions increase the failover time.

The following are some recommendations for working with Multi-AZ deployments for Microsoft SQL Server DB instances:

- For databases used in production or preproduction, we recommend the following options:
 - Multi-AZ deployments for high availability
 - "Provisioned IOPS" for fast, consistent performance
 - "Memory optimized" rather than "General purpose"
- You can't select the Availability Zone (AZ) for the secondary instance, so when you deploy application hosts, take this into account. Your database might fail over to another AZ, and the application hosts might not be in the same AZ as the database. For this reason, we recommend that you balance your application hosts across all AZs in the given AWS Region.
- For best performance, don't enable Database Mirroring or Always On AGs during a large data load operation. If you want your data load to be as fast as possible, finish loading data before you convert your DB instance to a Multi-AZ deployment.
- Applications that access the SQL Server databases should have exception handling that catches connection errors. The following code sample shows a try/catch block that catches a communication error. In this example, the break statement exits the while loop if the connection is successful, but retries up to 10 times if an exception is thrown.

```
int RetryMaxAttempts = 10;
int RetryIntervalPeriodInSeconds = 1;
int iRetryCount = 0;
while (iRetryCount < RetryMaxAttempts)
{
    using (SqlConnection connection = new SqlConnection(DatabaseConnectionString))
    {
        using (SqlCommand command = connection.CreateCommand())
        {
            command.CommandText = "INSERT INTO SOME_TABLE VALUES ('SomeValue');";
            try
            {
                connection.Open();
                command.ExecuteNonQuery();
                break;
            }
            catch (Exception ex)
            {
                Logger(ex.Message);
                iRetryCount++;
            }
        }
    }
}
```

```

        finally {
            connection.Close();
        }
    }
    Thread.Sleep(RetryIntervalPeriodInSeconds * 1000);
}

```

- Don't use the `Set Partner Off` command when working with Multi-AZ instances. For example, don't do the following.

```
--Don't do this
ALTER DATABASE db1 SET PARTNER off
```

- Don't set the recovery mode to `simple`. For example, don't do the following.

```
--Don't do this
ALTER DATABASE db1 SET RECOVERY simple
```

- Don't use the `DEFAULT_DATABASE` parameter when creating new logins on Multi-AZ DB instances, because these settings can't be applied to the standby mirror. For example, don't do the following.

```
--Don't do this
CREATE LOGIN [test_dba] WITH PASSWORD=foo, DEFAULT_DATABASE=[db2]
```

Also, don't do the following.

```
--Don't do this
ALTER LOGIN [test_dba] SET DEFAULT_DATABASE=[db3]
```

Determining the location of the secondary

You can determine the location of the secondary replica by using the AWS Management Console. You need to know the location of the secondary if you are setting up your primary DB instance in a VPC.

Instance		
Configuration	Instance class	Storage
DB instance id database-1	Instance class db.m4.large	Encryption Enabled
Engine version 14.00.3192.2.v1	vCPU 2	KMS key aws/rds
DB name -	RAM 8 GB	Storage type General Purpose (SSD)
License model License Included	Availability	IOPS -
Collation SQL_Latin1_General_CI_AS	Master username admin	Storage 20 GiB
Option groups default:sqlserver-se-14-00	IAM db authentication Not Enabled	Storage autoscaling Enabled
ARN arn:aws:rds:us-west-2: db:database-1	Multi AZ Yes (Mirroring)	Maximum storage threshold 1000 GiB
Resource id db-	Secondary Zone us-west-2c	

You can also view the Availability Zone of the secondary using the AWS CLI command `describe-db-instances` or RDS API operation `DescribeDBInstances`. The output shows the secondary AZ where the standby mirror is located.

Migrating from Database Mirroring to Always On availability groups

In version 14.00.3049.1 of Microsoft SQL Server Enterprise edition, Always On availability groups (AGs) is enabled by default.

To migrate from Database Mirroring (DBM) to AGs, first check your version. If you are using a DB instance with a version prior to Enterprise Edition 13.00.5216.0, modify the instance to patch it to 13.00.5216.0 or later. If you are using a DB instance with a version prior to Enterprise Edition 14.00.3049.1, modify the instance to patch it to 14.00.3049.1 or later.

If you want to upgrade a mirrored DB instance to use AGs, run the upgrade first, modify the instance to remove Multi-AZ, and then modify it again to add Multi-AZ. This converts your instance to use Always On AGs.

Additional features for Microsoft SQL Server on Amazon RDS

In the following sections, you can find information about augmenting Amazon RDS instances running the Microsoft SQL Server DB engine.

Topics

- [Using SSL with a Microsoft SQL Server DB instance \(p. 704\)](#)
- [Configuring security protocols and ciphers \(p. 707\)](#)
- [Using Windows Authentication with an Amazon RDS for SQL Server DB instance \(p. 711\)](#)
- [Integrating an Amazon RDS for SQL Server DB instance with Amazon S3 \(p. 721\)](#)
- [Using Database Mail on Amazon RDS for SQL Server \(p. 734\)](#)
- [Instance store support for the tempdb database on Amazon RDS for SQL Server \(p. 744\)](#)
- [Using extended events with Amazon RDS for Microsoft SQL Server \(p. 746\)](#)

Using SSL with a Microsoft SQL Server DB instance

You can use Secure Sockets Layer (SSL) to encrypt connections between your client applications and your Amazon RDS DB instances running Microsoft SQL Server. SSL support is available in all AWS regions for all supported SQL Server editions.

When you create a SQL Server DB instance, Amazon RDS creates an SSL certificate for it. The SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks.

There are 2 ways to use SSL to connect to your SQL Server DB instance:

- Force SSL for all connections — this happens transparently to the client, and the client doesn't have to do any work to use SSL.
- Encrypt specific connections — this sets up an SSL connection from a specific client computer, and you must do work on the client to encrypt connections.

For information about Transport Layer Security (TLS) support for SQL Server, see [TLS 1.2 support for Microsoft SQL Server](#).

Forcing connections to your DB instance to use SSL

You can force all connections to your DB instance to use SSL. If you force connections to use SSL, it happens transparently to the client, and the client doesn't have to do any work to use SSL.

If you want to force SSL, use the `rds.force_ssl` parameter. By default, the `rds.force_ssl` parameter is set to 0 (off). Set the `rds.force_ssl` parameter to 1 (on) to force connections to use SSL. The `rds.force_ssl` parameter is static, so after you change the value, you must reboot your DB instance for the change to take effect.

To force all connections to your DB instance to use SSL

1. Determine the parameter group that is attached to your DB instance:
 - a. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
 - b. In the top right corner of the Amazon RDS console, choose the AWS Region of your DB instance.
 - c. In the navigation pane, choose **Databases**, and then choose the name of your DB instance to show its details.
 - d. Choose the **Configuration** tab. Find the **Parameter group** in the section.
2. If necessary, create a new parameter group. If your DB instance uses the default parameter group, you must create a new parameter group. If your DB instance uses a nondefault parameter group, you can choose to edit the existing parameter group or to create a new parameter group. If you edit an existing parameter group, the change affects all DB instances that use that parameter group.

To create a new parameter group, follow the instructions in [Creating a DB parameter group \(p. 229\)](#).

3. Edit your new or existing parameter group to set the `rds.force_ssl` parameter to `true`. To edit the parameter group, follow the instructions in [Modifying parameters in a DB parameter group \(p. 232\)](#).
4. If you created a new parameter group, modify your DB instance to attach the new parameter group. Modify the **DB Parameter Group** setting of the DB instance. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).
5. Reboot your DB instance. For more information, see [Rebooting a DB instance \(p. 276\)](#).

Encrypting specific connections

You can force all connections to your DB instance to use SSL, or you can encrypt connections from specific client computers only. To use SSL from a specific client, you must obtain certificates for the client computer, import certificates on the client computer, and then encrypt the connections from the client computer.

Note

All SQL Server instances created after August 5, 2014, use the DB instance endpoint in the Common Name (CN) field of the SSL certificate. Prior to August 5, 2014, SSL certificate verification was not available for VPC-based SQL Server instances. If you have a VPC-based SQL Server DB instance that was created before August 5, 2014, and you want to use SSL certificate verification and ensure that the instance endpoint is included as the CN for the SSL certificate for that DB instance, then rename the instance. When you rename a DB instance, a new certificate is deployed and the instance is rebooted to enable the new certificate.

Obtaining certificates for client computers

To encrypt connections from a client computer to an Amazon RDS DB instance running Microsoft SQL Server, you need a certificate on your client computer.

To obtain that certificate, download the certificate to your client computer. You can download a root certificate that works for all regions. You can also download a certificate bundle that contains both the old and new root certificate. In addition, you can download region-specific intermediate certificates. For more information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 1634\)](#).

After you have downloaded the appropriate certificate, import the certificate into your Microsoft Windows operating system by following the procedure in the section following.

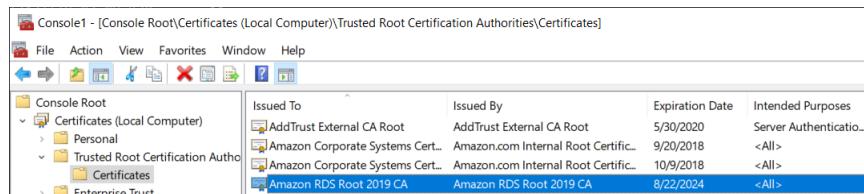

Importing certificates on client computers

You can use the following procedure to import your certificate into the Microsoft Windows operating system on your client computer.

To import the certificate into your Windows operating system:

1. On the **Start** menu, type **Run** in the search box and press **Enter**.
2. In the **Open** box, type **MMC** and then choose **OK**.
3. In the MMC console, on the **File** menu, choose **Add/Remove Snap-in**.
4. In the **Add or Remove Snap-ins** dialog box, for **Available snap-ins**, select **Certificates**, and then choose **Add**.
5. In the **Certificates snap-in** dialog box, choose **Computer account**, and then choose **Next**.
6. In the **Select computer** dialog box, choose **Finish**.
7. In the **Add or Remove Snap-ins** dialog box, choose **OK**.
8. In the MMC console, expand **Certificates**, open the context (right-click) menu for **Trusted Root Certification Authorities**, choose **All Tasks**, and then choose **Import**.
9. On the first page of the Certificate Import Wizard, choose **Next**.
10. On the second page of the Certificate Import Wizard, choose **Browse**. In the browse window, change the file type to **All files (*.*)** because .pem is not a standard certificate extension. Locate the .pem file that you downloaded previously.
11. Choose **Open** to select the certificate file, and then choose **Next**.
12. On the third page of the Certificate Import Wizard, choose **Next**.
13. On the fourth page of the Certificate Import Wizard, choose **Finish**. A dialog box appears indicating that the import was successful.

14. In the MMC console, expand **Certificates**, expand **Trusted Root Certification Authorities**, and then choose **Certificates**. Locate the certificate to confirm it exists, as shown here.

15. Restart your computer.

Encrypting connections to an Amazon RDS DB instance running Microsoft SQL Server

After you have imported a certificate into your client computer, you can encrypt connections from the client computer to an Amazon RDS DB instance running Microsoft SQL Server.

For SQL Server Management Studio, use the following procedure. For more information about SQL Server Management Studio, see [Use SQL Server management studio](#).

To encrypt connections from SQL Server Management Studio

1. Launch SQL Server Management Studio.
2. For **Connect to server**, type the server information, login user name, and password.
3. Choose **Options**.
4. Select **Encrypt connection**.
5. Choose **Connect**.
6. Confirm that your connection is encrypted by running the following query. Verify that the query returns `true` for `encrypt_option`.

```
select ENCRYPT_OPTION from SYS.DM_EXEC_CONNECTIONS where SESSION_ID = @@SPID
```

For any other SQL client, use the following procedure.

To encrypt connections from other SQL clients

1. Append `encrypt=true` to your connection string. This string might be available as an option, or as a property on the connection page in GUI tools.

Note

To enable SSL encryption for clients that connect using JDBC, you might need to add the Amazon RDS SQL certificate to the Java CA certificate (`cacerts`) store. You can do this by using the `keytool` utility.

2. Confirm that your connection is encrypted by running the following query. Verify that the query returns `true` for `encrypt_option`.

```
select ENCRYPT_OPTION from SYS.DM_EXEC_CONNECTIONS where SESSION_ID = @@SPID
```

Configuring security protocols and ciphers

You can turn certain security protocols and ciphers on and off using DB parameters. The security parameters that you can configure (except for TLS version 1.2) are shown in the following table.

A value of **default** means that the operating system default value is used, whether it is enabled or disabled.

Note

You can't disable TLS 1.2, because Amazon RDS uses it internally.

DB parameter	Allowed values (default in bold)	Description
rds.tls10	default , enabled, disabled	TLS 1.0.
rds.tls11	default , enabled, disabled	TLS 1.1.
rds.tls12	default	TLS 1.2. You can't modify this value.
rds.rc4	default , enabled, disabled	RC4 stream cipher.
rds.diffie-hellman	default , enabled, disabled	Diffie-Hellman key-exchange encryption.
rds.diffie-hellman-min-key-bit-length	default , 1024, 2048, 4096	Minimum bit length for Diffie-Hellman keys.
rds.curve25519	default , enabled, disabled	Curve25519 elliptic-curve encryption cipher. This parameter isn't supported for all engine versions.
rds.3des168	default , enabled, disabled	Triple Data Encryption Standard (DES) encryption cipher with a 168-bit key length.

Note

For more information on the default values for SQL Server security protocols and ciphers, see [Protocols in TLS/SSL \(Schannel SSP\)](#) and [Cipher Suites in TLS/SSL \(Schannel SSP\)](#) in the Microsoft documentation.

Use the following process to configure the security protocols and ciphers:

1. Create a custom DB parameter group.
2. Modify the parameters in the parameter group.
3. Associate the DB parameter group with your DB instance.

For more information on DB parameter groups, see [Working with DB parameter groups \(p. 228\)](#).

Creating the security-related parameter group

Create a parameter group for your security-related parameters that corresponds to the SQL Server edition and version of your DB instance.

Console

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
4. In the **Create parameter group** pane, do the following:
 - a. For **Parameter group family**, choose **sqlserver-se-13.0**.
 - b. For **Group name**, enter an identifier for the parameter group, such as **sqlserver-ciphers-se-13**.
 - c. For **Description**, enter **Parameter group for security protocols and ciphers**.
5. Choose **Create**.

CLI

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
    --db-parameter-group-name sqlserver-ciphers-se-13 \
    --db-parameter-group-family "sqlserver-se-13.0" \
    --description "Parameter group for security protocols and ciphers"
```

For Windows:

```
aws rds create-db-parameter-group ^
    --db-parameter-group-name sqlserver-ciphers-se-13 ^
    --db-parameter-group-family "sqlserver-se-13.0" ^
    --description "Parameter group for security protocols and ciphers"
```

Modifying security-related parameters

Modify the security-related parameters in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

Console

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016. This example turns off TLS version 1.0.

To modify the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group, such as **sqlserver-ciphers-se-13**.
4. Under **Parameters**, filter the parameter list for **rds**.
5. Choose **Edit parameters**.
6. Choose **rds.tls10**.
7. For **Values**, choose **disabled**.
8. Choose **Save changes**.

CLI

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016. This example turns off TLS version 1.0.

To modify the parameter group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
    --db-parameter-group-name sqlserver-ciphers-se-13 \
    --parameters
    "ParameterName='rds.tls10',ParameterValue='disabled',ApplyMethod=pending-reboot"
```

For Windows:

```
aws rds modify-db-parameter-group ^
    --db-parameter-group-name sqlserver-ciphers-se-13 ^
    --parameters
    "ParameterName='rds.tls10',ParameterValue='disabled',ApplyMethod=pending-reboot"
```

Associating the security-related parameter group with your DB instance

To associate the parameter group with your DB instance, use the AWS Management Console or the AWS CLI.

Console

You can associate the parameter group with a new or existing DB instance:

- For a new DB instance, associate it when you launch the instance. For more information, see [Creating an Amazon RDS DB instance \(p. 141\)](#).
- For an existing DB instance, associate it by modifying the instance. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

CLI

You can associate the parameter group with a new or existing DB instance.

To create a DB instance with the parameter group

- Specify the same DB engine type and major version as you used when creating the parameter group.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --db-instance-class db.m5.2xlarge \
    --engine sqlserver-se \
    --engine-version 13.00.5426.0.v1 \
    --allocated-storage 100 \
    --master-user-password secret123 \
    --master-username admin \
    --storage-type gp2 \
    --license-model li \
    --db-parameter-group-name sqlserver-ciphers-se-13
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --db-instance-class db.m5.2xlarge ^
    --engine sqlserver-se ^
    --engine-version 13.00.5426.0.v1 ^
    --allocated-storage 100 ^
    --master-user-password secret123 ^
    --master-username admin ^
    --storage-type gp2 ^
    --license-model li ^
    --db-parameter-group-name sqlserver-ciphers-se-13
```

To modify a DB instance and associate the parameter group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --db-parameter-group-name sqlserver-ciphers-se-13 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
    --db-instance-identifier mydbinstance ^
    --db-parameter-group-name sqlserver-ciphers-se-13 ^
    --apply-immediately
```

Using Windows Authentication with an Amazon RDS for SQL Server DB instance

You can use Microsoft Windows Authentication to authenticate users when they connect to your Amazon RDS for Microsoft SQL Server DB instance. The DB instance works with AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to enable Windows Authentication. When users authenticate with a SQL Server DB instance joined to the trusting domain, authentication requests are forwarded to the domain directory that you create with AWS Directory Service.

Amazon RDS supports Windows Authentication for SQL Server in all AWS Regions.

Amazon RDS uses mixed mode for Windows Authentication. This approach means that the *master user* (the name and password used to create your SQL Server DB instance) uses SQL Authentication. Because the master user account is a privileged credential, you should restrict access to this account.

To get Windows Authentication using an on-premises or self-hosted Microsoft Active Directory, create a forest trust. The trust can be one-way or two-way. For more information on setting up forest trusts using AWS Directory Service, see [When to create a trust relationship](#) in the *AWS Directory Service Administration Guide*.

To set up Windows authentication for a SQL Server DB instance, do the following steps, explained in greater detail in [Setting up Windows Authentication for SQL Server DB instances \(p. 712\)](#):

1. Use AWS Managed Microsoft AD, either from the AWS Management Console or AWS Directory Service API, to create an AWS Managed Microsoft AD directory.
2. If you use the AWS CLI or Amazon RDS API to create your SQL Server DB instance, create an AWS Identity and Access Management (IAM) role. This role uses the managed IAM policy `AmazonRDSDirectoryServiceAccess` and allows Amazon RDS to make calls to your directory. If you use the console to create your SQL Server DB instance, AWS creates the IAM role for you.
- For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see [Managing AWS STS in an AWS Region](#) in the *IAM User Guide*.
3. Create and configure users and groups in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users and groups in your Active Directory, see [Manage users and groups in AWS Managed Microsoft AD](#) in the *AWS Directory Service Administration Guide*.
4. If you plan to locate the directory and the DB instance in different VPCs, enable cross-VPC traffic.
5. Use Amazon RDS to create a new SQL Server DB instance either from the console, AWS CLI, or Amazon RDS API. In the create request, you provide the domain identifier ("d-*" identifier) that was generated when you created your directory and the name of the role you created. You can also modify an existing SQL Server DB instance to use Windows Authentication by setting the domain and IAM role parameters for the DB instance.
6. Use the Amazon RDS master user credentials to connect to the SQL Server DB instance as you do any other DB instance. Because the DB instance is joined to the AWS Managed Microsoft AD domain, you can provision SQL Server logins and users from the Active Directory users and groups in their domain. (These are known as SQL Server "Windows" logins.) Database permissions are managed through standard SQL Server permissions granted and revoked to these Windows logins.

Creating the endpoint for Kerberos authentication

Kerberos-based authentication requires that the endpoint be the customer-specified host name, a period, and then the fully qualified domain name (FQDN). For example, the following is an example of an

endpoint you might use with Kerberos-based authentication. In this example, the SQL Server DB instance host name is ad-test and the domain name is corp-ad.company.com.

```
ad-test.corp-ad.company.com
```

If you want to make sure your connection is using Kerberos, run the following query:

```
SELECT net_transport, auth_scheme
  FROM sys.dm_exec_connections
 WHERE session_id = @@SPID;
```

Setting up Windows Authentication for SQL Server DB instances

You use AWS Directory Service for Microsoft Active Directory, also called AWS Managed Microsoft AD, to set up Windows Authentication for a SQL Server DB instance. To set up Windows Authentication, take the following steps.

Step 1: Create a directory using the AWS Directory Service for Microsoft Active Directory

AWS Directory Service creates a fully managed, Microsoft Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name Service (DNS) servers on your behalf. The directory servers are created in two subnets in two different Availability Zones within a VPC. This redundancy helps ensure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up a Microsoft Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

Note

Be sure to save this password. AWS Directory Service doesn't store this password, and you can't retrieve or reset it.

- Creates a security group for the directory controllers.

When you launch an AWS Directory Service for Microsoft Active Directory, AWS creates an Organizational Unit (OU) that contains all your directory's objects. This OU, which has the NetBIOS name that you typed when you created your directory, is located in the domain root. The domain root is owned and managed by AWS.

The *admin* account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users, groups, and computers.
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users and groups in your OU.
- Create additional OUs and containers.
- Delegate authority.
- Create and link group policies.
- Restore deleted objects from the Active Directory Recycle Bin.
- Run AD and DNS Windows PowerShell modules on the Active Directory Web Service.

The admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders).
- View DNS event logs.
- View security event logs.

To create a directory with AWS Managed Microsoft AD

1. In the [AWS Directory Service console](#) navigation pane, choose **Directories** and choose **Set up directory**.
2. Choose **AWS Managed Microsoft AD**. This is the only option currently supported for use with Amazon RDS.
3. Choose **Next**.
4. On the **Enter directory information** page, provide the following information:

Edition

Choose the edition that meets your requirements.

Directory DNS name

The fully qualified name for the directory, such as `corp.example.com`. Names longer than 47 characters aren't supported by SQL Server.

Directory NetBIOS name

An optional short name for the directory, such as `CORP`.

Directory description

An optional description for the directory.

Admin password

The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

The directory administrator password can't include the word `admin`. The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a-z)
- Uppercase letters (A-Z)
- Numbers (0-9)
- Non-alphanumeric characters (~!@#\$%^&*_+=`|\{};:"<,>,?./)

Confirm password

Retype the administrator password.

5. Choose **Next**.
6. On the **Choose VPC and subnets** page, provide the following information:

VPC

Choose the VPC for the directory.

Note

You can locate the directory and the DB instance in different VPCs, but if you do so, make sure to enable cross-VPC traffic. For more information, see [Step 4: Enable cross-VPC traffic between the directory and the DB instance \(p. 716\)](#).

Subnets

Choose the subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Choose **Next**.
8. Review the directory information. If changes are needed, choose **Previous**. When the information is correct, choose **Create directory**.

Review & create

Review	
Directory type	VPC
Microsoft AD	vpc-8b6b78e9 ([REDACTED])
Directory DNS name	Subnets
corp.example.com	subnet-75128d10 ([REDACTED], us-east-1a) subnet-f51665dd ([REDACTED], us-east-1b)
Directory NetBIOS name	
CORP	
Directory description	
My directory

Edition	Free trial eligible Learn more 30-day limited trial
Standard	
~USD [REDACTED] *	
* Includes two domain controllers, USD [REDACTED] /mo for each additional domain controller.	

Cancel [Previous](#) **Create directory**

It takes several minutes for the directory to be created. When it has been successfully created, the **Status** value changes to **Active**.

To see information about your directory, choose the directory ID in the directory listing. Make a note of the **Directory ID**. You need this value when you create or modify your SQL Server DB instance.

The screenshot shows the 'Directory details' page for a Microsoft AD Standard edition. The 'Directory ID' field, which contains the value 'd-90670a8d36', is highlighted with a red oval. Other visible details include the VPC ('vpc-6594f31c'), Subnets ('subnet-7d36a227', 'subnet-a2ab49c6'), Status ('Active'), Last updated ('Tuesday, January 7, 2020'), Launch time ('Tuesday, January 7, 2020'), Availability zones ('us-east-1c, us-east-1d'), and DNS address ('[REDACTED]'). Below the main table, there are tabs for 'Application management' (which is selected), 'Scale & share', 'Networking & security', and 'Maintenance'.

Step 2: Create the IAM role for use by Amazon RDS

If you use the console to create your SQL Server DB instance, you can skip this step. If you use the CLI or RDS API to create your SQL Server DB instance, you must create an IAM role that uses the `AmazonRDSDirectoryServiceAccess` managed IAM policy. This role allows Amazon RDS to make calls to the AWS Directory Service for you.

If you are using a custom policy for joining a domain, rather than using the AWS-managed `AmazonRDSDirectoryServiceAccess` policy, make sure that you allow the `ds:GetAuthorizedApplicationDetails` action. This requirement is effective starting July 2019, due to a change in the AWS Directory Service API.

The following IAM policy, `AmazonRDSDirectoryServiceAccess`, provides access to AWS Directory Service.

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Action": [  
                "ds:DescribeDirectories",  
                "ds:AuthorizeApplication",  
                "ds:UnauthorizeApplication",  
                "ds:GetAuthorizedApplicationDetails"  
            ],  
            "Effect": "Allow",  
            "Resource": "*"  
        }  
    ]  
}
```

```
    ]  
}
```

Create an IAM role using this policy. For more information about creating IAM roles, see [Creating customer managed policies](#) in the *IAM User Guide*.

Step 3: Create and configure users and groups

You can create users and groups with the Active Directory Users and Computers tool. This tool is one of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. Users represent individual people or entities that have access to your directory. Groups are very useful for giving or denying privileges to groups of users, rather than having to apply those privileges to each individual user.

To create users and groups in an AWS Directory Service directory, you must be connected to a Windows EC2 instance that is a member of the AWS Directory Service directory. You must also be logged in as a user that has privileges to create users and groups. For more information, see [Add users and groups \(Simple AD and AWS Managed Microsoft AD\)](#) in the *AWS Directory Service Administration Guide*.

Step 4: Enable cross-VPC traffic between the directory and the DB instance

If you plan to locate the directory and the DB instance in the same VPC, skip this step and move on to [Step 5: Create or modify a SQL Server DB instance \(p. 716\)](#).

If you plan to locate the directory and the DB instance in different VPCs, configure cross-VPC traffic using VPC peering or [AWS Transit Gateway](#).

The following procedure enables traffic between VPCs using VPC peering. Follow the instructions in [What is VPC peering?](#) in the *Amazon Virtual Private Cloud Peering Guide*.

To enable cross-VPC traffic using VPC peering

1. Set up appropriate VPC routing rules to ensure that network traffic can flow both ways.
2. Ensure that the DB instance's security group can receive inbound traffic from the directory's security group.
3. Ensure that there is no network access control list (ACL) rule to block traffic.

If a different AWS account owns the directory, you must share the directory.

To share the directory between AWS accounts

1. Start sharing the directory with the AWS account that the DB instance will be created in by following the instructions in [Tutorial: Sharing your AWS Managed Microsoft AD directory for seamless EC2 domain-join](#) in the *AWS Directory Service Administration Guide*.
2. Sign in to the AWS Directory Service console using the account for the DB instance, and ensure that the domain has the SHARED status before proceeding.
3. While signed into the AWS Directory Service console using the account for the DB instance, note the **Directory ID** value. You use this directory ID to join the DB instance to the domain.

Step 5: Create or modify a SQL Server DB instance

Create or modify a SQL Server DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new SQL Server DB instance using the console, the [create-db-instance](#) CLI command, or the [CreateDBInstance](#) RDS API operation.

For instructions, see [Creating an Amazon RDS DB instance \(p. 141\)](#).
- Modify an existing SQL Server DB instance using the console, the [modify-db-instance](#) CLI command, or the [ModifyDBInstance](#) RDS API operation.

For instructions, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).
- Restore a SQL Server DB instance from a DB snapshot using the console, the [restore-db-instance-from-db-snapshot](#) CLI command, or the [RestoreDBInstanceFromDBSnapshot](#) RDS API operation.

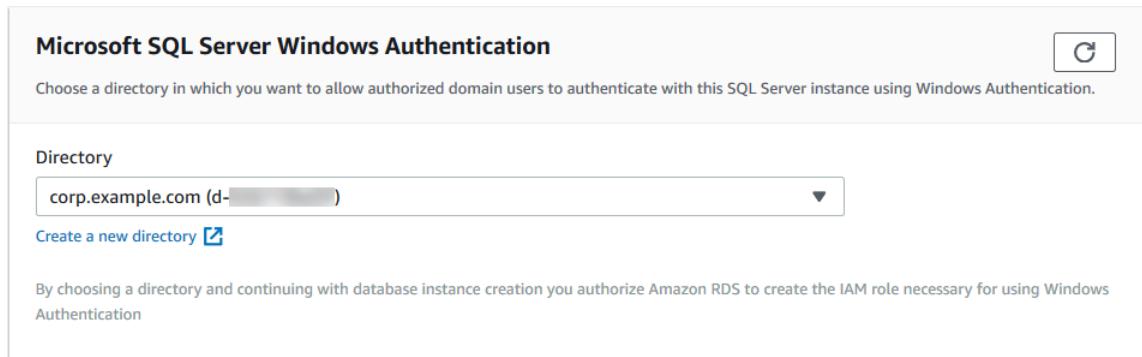

For instructions, see [Restoring from a DB snapshot \(p. 349\)](#).
- Restore a SQL Server DB instance to a point-in-time using the console, the [restore-db-instance-to-point-in-time](#) CLI command, or the [RestoreDBInstanceToPointInTime](#) RDS API operation.

For instructions, see [Restoring a DB instance to a specified time \(p. 389\)](#).

Windows Authentication is only supported for SQL Server DB instances in a VPC.

For the DB instance to be able to use the domain directory that you created, the following is required:

- For **Directory**, you must choose the domain identifier (`d-ID`) generated when you created the directory.
- Make sure that the VPC security group has an outbound rule that lets the DB instance communicate with the directory.

When you use the AWS CLI, the following parameters are required for the DB instance to be able to use the directory that you created:

- For the `--domain` parameter, use the domain identifier (`d-ID`) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role that you created that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--domain d-ID \
--domain-iam-role-name role-name
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--domain d-ID ^
--domain-iam-role-name role-name
```

Important

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

Step 6: Create Windows Authentication SQL Server logins

Use the Amazon RDS master user credentials to connect to the SQL Server DB instance as you do any other DB instance. Because the DB instance is joined to the AWS Managed Microsoft AD domain, you can provision SQL Server logins and users. You do this from the Active Directory users and groups in your domain. Database permissions are managed through standard SQL Server permissions granted and revoked to these Windows logins.

For an Active Directory user to authenticate with SQL Server, a SQL Server Windows login must exist for the user or a group that the user is a member of. Fine-grained access control is handled through granting and revoking permissions on these SQL Server logins. A user that doesn't have a SQL Server login or belong to a group with such a login can't access the SQL Server DB instance.

The ALTER ANY LOGIN permission is required to create an Active Directory SQL Server login. If you haven't created any logins with this permission, connect as the DB instance's master user using SQL Server Authentication.

Run a data definition language (DDL) command such as the following example to create a SQL Server login for an Active Directory user or group.

Note

Specify users and groups using the pre-Windows 2000 login name in the format *domainName\login_name*. You can't use a user principal name (UPN) in the format *login_name@DomainName*.

```
USE [master]
GO
CREATE LOGIN [mydomain\myuser] FROM WINDOWS WITH DEFAULT_DATABASE = [master],
DEFAULT_LANGUAGE = [us_english];
GO
```

For more information, see [CREATE LOGIN \(Transact-SQL\)](#) in the Microsoft Developer Network documentation.

Users (both humans and applications) from your domain can now connect to the RDS for SQL Server instance from a domain-joined client machine using Windows authentication.

Managing a DB instance in a Domain

You can use the console, AWS CLI, or the Amazon RDS API to manage your DB instance and its relationship with your domain. For example, you can move the DB instance into, out of, or between domains.

For example, using the Amazon RDS API, you can do the following:

- To reattempt a domain join for a failed membership, use the [ModifyDBInstance](#) API operation and specify the current membership's directory ID.
- To update the IAM role name for membership, use the [ModifyDBInstance](#) API operation and specify the current membership's directory ID and the new IAM role.
- To remove a DB instance from a domain, use the [ModifyDBInstance](#) API operation and specify `none` as the domain parameter.
- To move a DB instance from one domain to another, use the [ModifyDBInstance](#) API operation and specify the domain identifier of the new domain as the domain parameter.
- To list membership for each DB instance, use the [DescribeDBInstances](#) API operation.

Understanding Domain membership

After you create or modify your DB instance, the instance becomes a member of the domain. The AWS console indicates the status of the domain membership for the DB instance. The status of the DB instance can be one of the following:

- **joined** – The instance is a member of the domain.
- **joining** – The instance is in the process of becoming a member of the domain.
- **pending-join** – The instance membership is pending.
- **pending-maintenance-join** – AWS will attempt to make the instance a member of the domain during the next scheduled maintenance window.
- **pending-removal** – The removal of the instance from the domain is pending.
- **pending-maintenance-removal** – AWS will attempt to remove the instance from the domain during the next scheduled maintenance window.
- **failed** – A configuration problem has prevented the instance from joining the domain. Check and fix your configuration before reissuing the instance modify command.
- **removing** – The instance is being removed from the domain.

A request to become a member of a domain can fail because of a network connectivity issue or an incorrect IAM role. For example, you might create a DB instance or modify an existing instance and have the attempt fail for the DB instance to become a member of a domain. In this case, either reissue the command to create or modify the DB instance or modify the newly created instance to join the domain.

Connecting to SQL Server with Windows authentication

To connect to SQL Server with Windows Authentication, you must be logged into a domain-joined computer as a domain user. After launching SQL Server Management Studio, choose **Windows Authentication** as the authentication type, as shown following.

Restoring a SQL Server DB instance and then adding it to a domain

You can restore a DB snapshot or do point-in-time recovery (PITR) for a SQL Server DB instance and then add it to a domain. Once the DB instance is restored, modify the instance using the process explained in [Step 5: Create or modify a SQL Server DB instance \(p. 716\)](#) to add the DB instance to a domain.

Integrating an Amazon RDS for SQL Server DB instance with Amazon S3

You can transfer files between a DB instance running Amazon RDS for SQL Server and an Amazon S3 bucket. By doing this, you can use Amazon S3 with SQL Server features such as BULK INSERT. For example, you can download .csv, .xml, .txt, and other files from Amazon S3 to the DB instance host and import the data from D:\S3\ into the database. All files are stored in D:\S3\ on the DB instance.

The following limitations apply:

- Files in the D:\S3 folder are deleted on the standby replica after a failover on Multi-AZ instances. For more information, see [Multi-AZ limitations for S3 integration \(p. 731\)](#).
- The DB instance and the S3 bucket must be in the same AWS Region.
- If you run more than one S3 integration task at a time, the tasks run sequentially, not in parallel.

Note

S3 integration tasks share the same queue as native backup and restore tasks. At maximum, you can have only two tasks in progress at any time in this queue. Therefore, two running native backup and restore tasks will block any S3 integration tasks.

- You must re-enable the S3 integration feature on restored instances. S3 integration isn't propagated from the source instance to the restored instance. Files in D:\S3 are deleted on a restored instance.
- Downloading to the DB instance is limited to 100 files. In other words, there can't be more than 100 files in D:\S3\.
- Only files without file extensions or with the following file extensions are supported for download: .abf, .asdatabase, .bcp, .configsettings, .csv, .dat, .deploymentoptions, .deploymenttargets, .fmt, .info, .isp and .xmla.
- The S3 bucket must have the same owner as the related AWS Identity and Access Management (IAM) role. Therefore, cross-account S3 integration isn't supported.
- The S3 bucket can't be open to the public.
- The file size for uploads from RDS to S3 is limited to 50 GB per file.
- The file size for downloads from S3 to RDS is limited to the maximum supported by S3.

- [Disabling RDS for SQL Server integration with S3 \(p. 732\)](#)

For more information on working with files in Amazon S3, see [Getting started with Amazon Simple Storage Service](#).

Prerequisites for integrating RDS for SQL Server with S3

Before you begin, find or create the S3 bucket that you want to use. Also, add permissions so that the RDS DB instance can access the S3 bucket. To configure this access, you create both an IAM policy and an IAM role.

Console

To create an IAM policy for access to Amazon S3

1. In the [IAM Management Console](#), choose **Policies** in the navigation pane.
2. Create a new policy, and use the **Visual editor** tab for the following steps.
3. For **Service**, enter **s3** and then choose the **S3** service.
4. For **Actions**, choose the following to grant the access that your DB instance requires:
 - `ListAllMyBuckets` – required
 - `ListBucket` – required
 - `GetBucketACL` – required
 - `GetBucketLocation` – required
 - `GetObject` – required for downloading files from S3 to `D:\S3\`
 - `PutObject` – required for uploading files from `D:\S3\` to S3
 - `ListMultipartUploadParts` – required for uploading files from `D:\S3\` to S3
 - `AbortMultipartUpload` – required for uploading files from `D:\S3\` to S3
5. For **Resources**, the options that display depend on which actions you choose in the previous step. You might see options for **bucket**, **object**, or both. For each of these, add the appropriate Amazon Resource Name (ARN).

For **bucket**, add the ARN for the bucket that you want to use. For example, if your bucket is named `example-bucket`, set the ARN to `arn:aws:s3:::example-bucket`.

For **object**, enter the ARN for the bucket and then choose one of the following:

- To grant access to all files in the specified bucket, choose **Any** for both **Bucket name** and **Object name**.
 - To grant access to specific files or folders in the bucket, provide ARNs for the specific buckets and objects that you want SQL Server to access.
6. Follow the instructions in the console until you finish creating the policy.

The preceding is an abbreviated guide to setting up a policy. For more detailed instructions on creating IAM policies, see [Creating IAM policies](#) in the *IAM User Guide*.

To create an IAM role that uses the IAM policy from the previous procedure

1. In the [IAM Management Console](#), choose **Roles** in the navigation pane.
2. Create a new IAM role, and choose the following options as they appear in the console:
 - **AWS service**
 - **RDS**
 - **RDS – Add Role to Database**

Then choose **Next:Permissions** at the bottom.

3. For **Attach permissions policies**, enter the name of the IAM policy that you previously created. Then choose the policy from the list.
4. Follow the instructions in the console until you finish creating the role.

The preceding is an abbreviated guide to setting up a role. If you want more detailed instructions on creating roles, see [IAM roles](#) in the *IAM User Guide*.

AWS CLI

To grant Amazon RDS access to an Amazon S3 bucket

1. Create an IAM policy that grants Amazon RDS access to an S3 bucket.

Include the appropriate actions to grant the access your DB instance requires:

- `ListAllMyBuckets` – required
- `ListBucket` – required
- `GetBucketACL` – required
- `GetBucketLocation` – required
- `GetObject` – required for downloading files from S3 to D:\S3\
- `PutObject` – required for uploading files from D:\S3\ to S3
- `ListMultipartUploadParts` – required for uploading files from D:\S3\ to S3
- `AbortMultipartUpload` – required for uploading files from D:\S3\ to S3

The following AWS CLI command creates an IAM policy named `rds-s3-integration-policy` with these options. It grants access to a bucket named `your-s3-bucket-arn`.

Example

For Linux, macOS, or Unix:

```
aws iam create-policy \
--policy-name rds-s3-integration-policy \
--policy-document '{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "s3>ListAllMyBuckets",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3>ListBucket",
                "s3>GetBucketACL",
                "s3>GetBucketLocation"
            ],
            "Resource": "arn:aws:s3:::bucket_name"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3>GetObject",
                "s3>PutObject",
                "s3>ListMultipartUploadParts",
                "s3>AbortMultipartUpload"
            ],
            "Resource": "arn:aws:s3:::bucket_name/key_prefix/*"
        }
    ]
}'
```

For Windows:

Make sure to change the line endings to the ones supported by your interface (^ instead of \). Also, in Windows, you must escape all double quotes with a \. To avoid the need to escape the quotes in the JSON, you can save it to a file instead and pass that in as a parameter.

First, create the `policy.json` file with the following permission policy:

```
{  
    "Version": "2012-10-17",  
    "Statement": [  
        {  
            "Effect": "Allow",  
            "Action": "s3>ListAllMyBuckets",  
            "Resource": "*"  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3>ListBucket",  
                "s3:GetBucketACL",  
                "s3:GetBucketLocation"  
            ],  
            "Resource": "arn:aws:s3:::bucket_name"  
        },  
        {  
            "Effect": "Allow",  
            "Action": [  
                "s3GetObject",  
                "s3PutObject",  
                "s3>ListMultipartUploadParts",  
                "s3AbortMultipartUpload"  
            ],  
            "Resource": "arn:aws:s3:::bucket_name/key_prefix/*"  
        }  
    ]  
}
```

Then use the following command to create the policy:

```
aws iam create-policy ^  
    --policy-name rds-s3-integration-policy ^  
    --policy-document file:///policy_file_path
```

2. After the policy is created, note the Amazon Resource Name (ARN) of the policy. You need the ARN for a later step.
3. Create an IAM role that Amazon RDS can assume on your behalf to access your S3 buckets.

The following AWS CLI command creates the `rds-s3-integration-role` for this purpose.

Example

For Linux, macOS, or Unix:

```
aws iam create-role \  
    --role-name rds-s3-integration-role \  
    --assume-role-policy-document '{  
        "Version": "2012-10-17",  
        "Statement": [  
            {  
                "Effect": "Allow",  
                "Principal": {
```

```
        "Service": "rds.amazonaws.com"
    },
    "Action": "sts:AssumeRole"
]
}'
```

For Windows:

Make sure to change the line endings to the ones supported by your interface (^ instead of \). Also, in Windows, you must escape all double quotes with a \. To avoid the need to escape the quotes in the JSON, you can save it to a file instead and pass that in as a parameter.

First, create the `assume_role_policy.json` file with the following policy:

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "rds.amazonaws.com"
                ]
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

Then use the following command to create the IAM role:

```
aws iam create-role ^
--role-name rds-s3-integration-role ^
--assume-role-policy-document file://assume_role_policy_file_path
```

For more information, see [Creating a role to delegate permissions to an IAM user](#) in the *IAM User Guide*.

4. After the IAM role is created, note the ARN of the role. You need the ARN for a later step.
5. Attach the IAM policy that you created to the IAM role that you created.

The following AWS CLI command attaches the policy to the role named `rds-s3-integration-role`.

Example

For Linux, macOS, or Unix:

```
aws iam attach-role-policy \
--policy-arn your-policy-arn \
--role-name rds-s3-integration-role
```

For Windows:

```
aws iam attach-role-policy ^
--policy-arn your-policy-arn ^
--role-name rds-s3-integration-role
```

Replace *your-policy-arn* with the policy ARN that you noted in a previous step.

Enabling RDS for SQL Server integration with S3

In the following section, you can find how to enable Amazon S3 integration with Amazon RDS for SQL Server. To work with S3 integration, your DB instance must be associated with the IAM role that you previously created before you use the `S3_INTEGRATION` feature-name parameter.

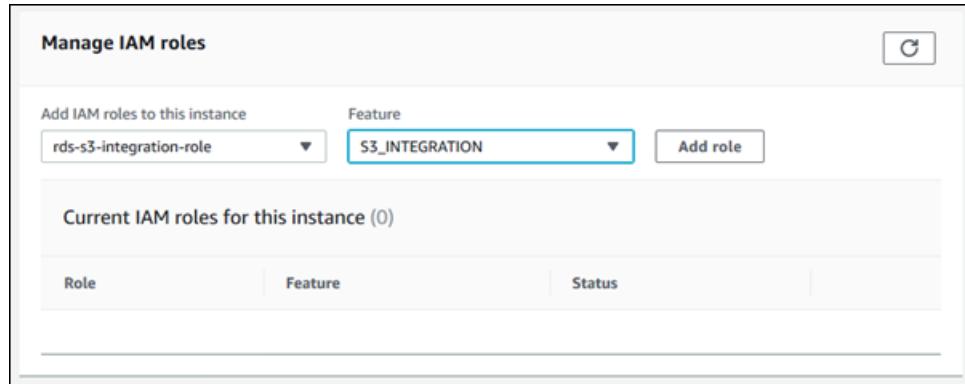

Note

To add an IAM role to a DB instance, the status of the DB instance must be **available**.

Console

To associate your IAM role with your DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose the RDS for SQL Server DB instance name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the IAM role to add for **Add IAM roles to this instance**.
4. For **Feature**, choose `S3_INTEGRATION`.

5. Choose **Add role**.

AWS CLI

To add the IAM role to the RDS for SQL Server DB instance

- The following AWS CLI command adds your IAM role to an RDS for SQL Server DB instance named *mydbinstance*.

Example

For Linux, macOS, or Unix:

```
aws rds add-role-to-db-instance \
    --db-instance-identifier mydbinstance \
    --feature-name S3_INTEGRATION \
    --role-arn your-role-arn
```

For Windows:

```
aws rds add-role-to-db-instance ^
--db-instance-identifier mydbinstance ^
--feature-name S3_INTEGRATION ^
--role-arn your-role-arn
```

Replace *your-role-arn* with the role ARN that you noted in a previous step. S3_INTEGRATION must be specified for the --feature-name option.

Transferring files between RDS for SQL Server and Amazon S3

You can use Amazon RDS stored procedures to download and upload files between Amazon S3 and your RDS DB instance. You can also use Amazon RDS stored procedures to list and delete files on the RDS instance.

The files that you download from and upload to S3 are stored in the D:\S3 folder. This is the only folder that you can use to access your files. You can organize your files into subfolders, which are created for you when you include the destination folder during download.

Some of the stored procedures require that you provide an Amazon Resource Name (ARN) to your S3 bucket and file. The format for your ARN is arn:aws:s3:::bucket_name/file_name. Amazon S3 doesn't require an account number or AWS Region in ARNs.

S3 integration tasks run sequentially and share the same queue as native backup and restore tasks. At maximum, you can have only two tasks in progress at any time in this queue. It can take up to five minutes for the task to begin processing.

Downloading files from an Amazon S3 bucket to a SQL Server DB instance

To download files from an S3 bucket to an RDS for SQL Server DB instance, use the Amazon RDS stored procedure msdb.dbo.rds_download_from_s3 with the following parameters.

Parameter name	Data type	Default	Required	Description
@s3_arn_of_file	NVARCHAR	–	Required	The S3 ARN of the file to download, for example: arn:aws:s3:::bucket_name/mydata.csv
@rds_file_path	NVARCHAR	–	Optional	The file path for the RDS instance. If not specified, the file path is D:\S3\<filename in s3>. RDS supports absolute paths and relative paths. If you want to create a subfolder, include it in the file path.
@overwrite_file	INT	0	Optional	Overwrite the existing file: 0 = Don't overwrite 1 = Overwrite

You can download files without a file extension and files with the following file extensions: .bcp, .csv, .dat, .fmt, .info, .lst, .tbl, .txt, and .xml.

Note

Files with the .ispac file extension are supported for download when SQL Server Integration Services is enabled. For more information on enabling SSIS, see [SQL Server Integration Services \(p. 773\)](#).

Files with the following file extensions are supported for download when SQL Server Analysis Services is enabled: .abf, .asdatabase, .configsettings, .deploymentoptions, .deploymenttargets, and .xmla. For more information on enabling SSAS, see [SQL Server Analysis Services \(p. 762\)](#).

The following example shows the stored procedure to download files from S3.

```
exec msdb.dbo.rds_download_from_s3
    @s3_arn_of_file='arn:aws:s3:::bucket_name/bulk_data.csv',
    @rds_file_path='D:\S3\seed_data\data.csv',
    @overwrite_file=1;
```

The example `rds_download_from_s3` operation creates a folder named `seed_data` in `D:\S3\`, if the folder doesn't exist yet. Then the example downloads the source file `bulk_data.csv` from S3 to a new file named `data.csv` on the DB instance. If the file previously existed, it's overwritten because the `@overwrite_file` parameter is set to 1.

Uploading files from a SQL Server DB instance to an Amazon S3 bucket

To upload files from an RDS for SQL Server DB instance to an S3 bucket, use the Amazon RDS stored procedure `msdb.dbo.rds_upload_to_s3` with the following parameters.

Parameter name	Data type	Default	Required	Description
<code>@s3_arn_of_file</code>	NVARCHAR	–	Required	The S3 ARN of the file to be created in S3, for example: <code>arn:aws:s3:::bucket_name/mydata.csv</code>
<code>@rds_file_path</code>	NVARCHAR	–	Required	The file path of the file to upload to S3. Absolute and relative paths are supported.
<code>@overwrite_file</code>	INT	–	Optional	Overwrite the existing file: 0 = Don't overwrite 1 = Overwrite

The following example uploads the file named `data.csv` from the specified location in `D:\S3\seed_data\` to a file `new_data.csv` in the S3 bucket specified by the ARN.

```
exec msdb.dbo.rds_upload_to_s3
    @rds_file_path='D:\S3\seed_data\data.csv',
    @s3_arn_of_file='arn:aws:s3:::bucket_name/new_data.csv',
    @overwrite_file=1;
```

If the file previously existed in S3, it's overwritten because the `@overwrite_file` parameter is set to 1.

Listing files on the RDS DB instance

To list the files available on the DB instance, use both a stored procedure and a function. First, run the following stored procedure to gather file details from the files in `D:\S3\`.

```
exec msdb.dbo.rds_gather_file_details;
```

The stored procedure returns the ID of the task. Like other tasks, this stored procedure runs asynchronously. As soon as the status of the task is **SUCCESS**, you can use the task ID in the `rds_fn_list_file_details` function to list the existing files and directories in D:\S3\, as shown following.

```
SELECT * FROM msdb.dbo.rds_fn_list_file_details(TASK_ID);
```

The `rds_fn_list_file_details` function returns a table with the following columns.

Output parameter	Description
<code>filepath</code>	Absolute path of the file (for example, D:\S3\mydata.csv)
<code>size_in_bytes</code>	File size (in bytes)
<code>last_modified_utc</code>	Last modification date and time in UTC format
<code>is_directory</code>	Option that indicates whether the item is a directory (true/false)

Deleting files on the RDS DB instance

To delete the files available on the DB instance, use the Amazon RDS stored procedure `msdb.dbo.rds_delete_from_filesystem` with the following parameters.

Parameter name	Data type	Default	Required	Description
<code>@rds_file_path</code>	NVARCHAR	–	Required	The file path of the file to delete. Absolute and relative paths are supported.
<code>@force_delete</code>	INT	0	Optional	To delete a directory, this flag must be included and set to 1. 1 = delete a directory This parameter is ignored if you are deleting a file.

To delete a directory, the `@rds_file_path` must end with a backslash (\) and `@force_delete` must be set to 1.

The following example deletes the file D:\S3\delete_me.txt.

```
exec msdb.dbo.rds_delete_from_filesystem
@rds_file_path='D:\S3\delete_me.txt';
```

The following example deletes the directory D:\S3\example_folder\.

```
exec msdb.dbo.rds_delete_from_filesystem
@rds_file_path='D:\S3\example_folder\' ,
@force_delete=1;
```

Monitoring the status of a file transfer task

To track the status of your S3 integration task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be `NULL` because it doesn't apply to S3 integration. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to `NULL` and the second parameter to 0, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,0);
```

To get a specific task, set the first parameter to `NULL` and the second parameter to the task ID, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,42);
```

The `rds_fn_task_status` function returns the following information.

Output parameter	Description
<code>task_id</code>	The ID of the task.
<code>task_type</code>	For S3 integration, tasks can have the following task types: <ul style="list-style-type: none">• <code>DOWNLOAD_FROM_S3</code>• <code>UPLOAD_TO_S3</code>• <code>LIST_FILES_ON_DISK</code>• <code>DELETE_FILES_ON_DISK</code>
<code>database_name</code>	Not applicable to S3 integration tasks.
<code>% complete</code>	The progress of the task as a percentage.
<code>duration(mins)</code>	The amount of time spent on the task, in minutes.
<code>lifecycle</code>	The status of the task. Possible statuses are the following: <ul style="list-style-type: none">• <code>CREATED</code> – After you call one of the S3 integration stored procedures, a task is created and the status is set to <code>CREATED</code>.• <code>IN_PROGRESS</code> – After a task starts, the status is set to <code>IN_PROGRESS</code>. It can take up to five minutes for the status to change from <code>CREATED</code> to <code>IN_PROGRESS</code>.• <code>SUCCESS</code> – After a task completes, the status is set to <code>SUCCESS</code>.• <code>ERROR</code> – If a task fails, the status is set to <code>ERROR</code>. For more information about the error, see the <code>task_info</code> column.

Output parameter	Description
	<ul style="list-style-type: none"> CANCEL_REQUESTED – After you call <code>rds_cancel_task</code>, the status of the task is set to CANCEL_REQUESTED. CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED.
<code>task_info</code>	Additional information about the task. If an error occurs during processing, this column contains information about the error.
<code>last_updated</code>	The date and time that the task status was last updated.
<code>created_at</code>	The date and time that the task was created.
<code>S3_object_arn</code>	The ARN of the S3 object downloaded from or uploaded to.
<code>overwrite_S3_backup_file</code>	Not applicable to S3 integration tasks.
<code>KMS_master_key_arn</code>	Not applicable to S3 integration tasks.
<code>filepath</code>	The file path on the RDS DB instance.
<code>overwrite_file</code>	An option that indicates if an existing file is overwritten.
<code>task_metadata</code>	Not applicable to S3 integration tasks.

Canceling a task

To cancel S3 integration tasks, use the `msdb.dbo.rds_cancel_task` stored procedure with the `task_id` parameter. Delete and list tasks that are in progress can't be cancelled. The following example shows a request to cancel a task.

```
exec msdb.dbo.rds_cancel_task @task_id = 1234;
```

To get an overview of all tasks and their task IDs, use the `rds_fn_task_status` function as described in [Monitoring the status of a file transfer task \(p. 730\)](#).

Multi-AZ limitations for S3 integration

On Multi-AZ instances, files in the `D:\S3` folder are deleted on the standby replica after a failover. A failover can be planned, for example, during DB instance modifications such as changing the instance class or upgrading the engine version. Or a failover can be unplanned, during an outage of the primary.

Note

We don't recommend using the `D:\S3` folder for file storage. The best practice is to upload created files to Amazon S3 to make them durable, and download files when you need to import data.

To determine the last failover time, you can use the `msdb.dbo.rds_failover_time` stored procedure. For more information, see [Determining the last failover time \(p. 817\)](#).

Example of no recent failover

This example shows the output when there is no recent failover in the error logs. No failover has happened since 2020-04-29 23:59:00.01.

Therefore, all files downloaded after that time that haven't been deleted using the `rds_delete_from_filesystem` stored procedure are still accessible on the current host. Files downloaded before that time might also be available.

errorlog_available_from	recent_failover_time
2020-04-29 23:59:00.0100000	null

Example of recent failover

This example shows the output when there is a failover in the error logs. The most recent failover was at 2020-05-05 18:57:51.89.

All files downloaded after that time that haven't been deleted using the `rds_delete_from_filesystem` stored procedure are still accessible on the current host.

errorlog_available_from	recent_failover_time
2020-04-29 23:59:00.0100000	2020-05-05 18:57:51.8900000

Disabling RDS for SQL Server integration with S3

Following, you can find how to disable Amazon S3 integration with Amazon RDS for SQL Server. Files in D:\S3\ aren't deleted when disabling S3 integration.

Note

To remove an IAM role from a DB instance, the status of the DB instance must be available.

Console

To disassociate your IAM role from your DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Choose the RDS for SQL Server DB instance name to display its details.
3. On the **Connectivity & security** tab, in the **Manage IAM roles** section, choose the IAM role to remove.
4. Choose **Delete**.

AWS CLI

To remove the IAM role from the RDS for SQL Server DB instance

- The following AWS CLI command removes the IAM role from a RDS for SQL Server DB instance named `mydbinstance`.

Example

For Linux, macOS, or Unix:

```
aws rds remove-role-from-db-instance \
--db-instance-identifier mydbinstance \
--feature-name S3_INTEGRATION \
--role-arn your-role-arn
```

For Windows:

```
aws rds remove-role-from-db-instance ^
--db-instance-identifier mydbinstance ^
--feature-name S3_INTEGRATION ^
--role-arn your-role-arn
```

Replace *your-role-arn* with the appropriate IAM role ARN for the --feature-name option.

Using Database Mail on Amazon RDS for SQL Server

You can use Database Mail to send email messages to users from your Amazon RDS on SQL Server database instance. The messages can contain files and query results. Database Mail includes the following components:

- **Configuration and security objects** – These objects create profiles and accounts, and are stored in the msdb database.
- **Messaging objects** – These objects include the `sp_send_dbmail` stored procedure used to send messages, and data structures that hold information about messages. They're stored in the msdb database.
- **Logging and auditing objects** – Database Mail writes logging information to the msdb database and the Microsoft Windows application event log.
- **Database Mail executable** – `DatabaseMail.exe` reads from a queue in the msdb database and sends email messages.

RDS supports Database Mail for all SQL Server versions on the Web, Standard, and Enterprise Editions.

Limitations

The following limitations apply to using Database Mail on your SQL Server DB instance:

- Database Mail isn't supported for SQL Server Express Edition.
- Modifying Database Mail configuration parameters isn't supported. To see the preset (default) values, use the `sysmail_help_configure_sp` stored procedure.
- File attachments aren't fully supported. For more information, see [Working with file attachments \(p. 743\)](#).
- The maximum file attachment size is 1 MB.
- Database Mail requires additional configuration on Multi-AZ DB instances. For more information, see [Considerations for Multi-AZ deployments \(p. 743\)](#).
- Configuring SQL Server Agent to send email messages to predefined operators isn't supported.

Enabling Database Mail

Use the following process to enable Database Mail for your DB instance:

1. Create a new parameter group.
2. Modify the parameter group to set the `database mail xps` parameter to 1.
3. Associate the parameter group with the DB instance.

Creating the parameter group for Database Mail

Create a parameter group for the `database mail xps` parameter that corresponds to the SQL Server edition and version of your DB instance.

Note

You can also modify an existing parameter group. Follow the procedure in [Modifying the parameter that enables Database Mail \(p. 735\)](#).

Console

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
4. In the **Create parameter group** pane, do the following:
 - a. For **Parameter group family**, choose **sqlserver-se-13.0**.
 - b. For **Group name**, enter an identifier for the parameter group, such as **dbmail-sqlserver-se-13**.
 - c. For **Description**, enter **Database Mail XPs**.
5. Choose **Create**.

CLI

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
--db-parameter-group-name dbmail-sqlserver-se-13 \
--db-parameter-group-family "sqlserver-se-13.0" \
--description "Database Mail XPs"
```

For Windows:

```
aws rds create-db-parameter-group ^
--db-parameter-group-name dbmail-sqlserver-se-13 ^
--db-parameter-group-family "sqlserver-se-13.0" ^
--description "Database Mail XPs"
```

Modifying the parameter that enables Database Mail

Modify the `database mail xps` parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

To enable Database Mail, set the `database mail xps` parameter to 1.

Console

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.

3. Choose the parameter group, such as **dbmail-sqlserver-se-13**.
4. Under **Parameters**, filter the parameter list for **mail**.
5. Choose **database mail xps**.
6. Choose **Edit parameters**.
7. Enter **1**.
8. Choose **Save changes**.

CLI

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name dbmail-sqlserver-se-13 \
--parameters "ParameterName='database mail
xps',ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name dbmail-sqlserver-se-13 ^
--parameters "ParameterName='database mail
xps',ParameterValue=1,ApplyMethod=immediate"
```

Associating the parameter group with the DB instance

You can use the AWS Management Console or the AWS CLI to associate the Database Mail parameter group with the DB instance.

Console

You can associate the Database Mail parameter group with a new or existing DB instance.

- For a new DB instance, associate it when you launch the instance. For more information, see [Creating an Amazon RDS DB instance \(p. 141\)](#).
- For an existing DB instance, associate it by modifying the instance. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

CLI

You can associate the Database Mail parameter group with a new or existing DB instance.

To create a DB instance with the Database Mail parameter group

- Specify the same DB engine type and major version as you used when creating the parameter group.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--db-instance-identifier mydbinstance \
--db-instance-class db.m5.2xlarge \
--engine sqlserver-se \
--engine-version 13.00.5426.0.v1 \
--allocated-storage 100 \
--master-user-password secret123 \
--master-username admin \
--storage-type gp2 \
--license-model li \
--db-parameter-group-name dbmail-sqlserver-se-13
```

For Windows:

```
aws rds create-db-instance ^
--db-instance-identifier mydbinstance ^
--db-instance-class db.m5.2xlarge ^
--engine sqlserver-se ^
--engine-version 13.00.5426.0.v1 ^
--allocated-storage 100 ^
--master-user-password secret123 ^
--master-username admin ^
--storage-type gp2 ^
--license-model li ^
--db-parameter-group-name dbmail-sqlserver-se-13
```

To modify a DB instance and associate the Database Mail parameter group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--db-parameter-group-name dbmail-sqlserver-se-13 \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--db-parameter-group-name dbmail-sqlserver-se-13 ^
--apply-immediately
```

Configuring Database Mail

You perform the following tasks to configure Database Mail:

1. Create the Database Mail profile.

2. Create the Database Mail account.
3. Add the Database Mail account to the Database Mail profile.
4. Add users to the Database Mail profile.

Note

To configure Database Mail, make sure that you have `execute` permission on the stored procedures in the `msdb` database.

Creating the Database Mail profile

To create the Database Mail profile, you use the `sysmail_add_profile_sp` stored procedure. The following example creates a profile named `Notifications`.

To create the profile

- Use the following SQL statement.

```
USE msdb
GO

EXECUTE msdb.dbo.sysmail_add_profile_sp
    @profile_name      = 'Notifications',
    @description       = 'Profile used for sending outgoing notifications using
Gmail.';
GO
```

Creating the Database Mail account

To create the Database Mail account, you use the `sysmail_add_account_sp` stored procedure. The following example creates an account named `Gmail`.

To create the account

- Use the following SQL statement.

```
USE msdb
GO

EXECUTE msdb.dbo.sysmail_add_account_sp
    @account_name      = 'Gmail',
    @description        = 'Mail account for sending outgoing notifications.',
    @email_address     = 'dbmail-test@gmail.com',
    @display_name       = 'Automated Mailer',
    @mailserver_name   = 'smtp.gmail.com',
    @port               = 587,
    @enable_ssl         = 1,
    @username           = 'dbmail-test@gmail.com',
    @password           = 'mypassword';
GO
```

Adding the Database Mail account to the Database Mail profile

To add the Database Mail account to the Database Mail profile, you use the `sysmail_add_profileaccount_sp` stored procedure. The following example adds the `Gmail` account to the `Notifications` profile.

To add the account to the profile

- Use the following SQL statement.

```
USE msdb
GO

EXECUTE msdb.dbo.sysmail_add_profileaccount_sp
    @profile_name      = 'Notifications',
    @account_name      = 'Gmail',
    @sequence_number   = 1;
GO
```

Adding users to the Database Mail profile

To grant permission for an msdb database principal to use a Database Mail profile, you use the [sysmail_add_principalprofile_sp](#) stored procedure. A *principal* is an entity that can request SQL Server resources. The database principal must map to a SQL Server authentication user, a Windows Authentication user, or a Windows Authentication group.

The following example grants public access to the Notifications profile.

To add a user to the profile

- Use the following SQL statement.

```
USE msdb
GO

EXECUTE msdb.dbo.sysmail_add_principalprofile_sp
    @profile_name      = 'Notifications',
    @principal_name    = 'public',
    @is_default        = 1;
GO
```

Amazon RDS stored procedures and functions for Database Mail

In addition to the [stored procedures](#) provided by Microsoft, RDS provides the stored procedures and functions for Database Mail shown in the following table.

Procedure/Function	Description
rds_fn_sysmail_allitems	Shows sent messages, including those submitted by other users.
rds_fn_sysmail_event_log	Shows events, including those for messages submitted by other users.
rds_fn_sysmail_mailattachments	Shows attachments, including those to messages submitted by other users.
rds_sysmail_control	Starts and stops the mail queue (DatabaseMail.exe process).
rds_sysmail_delete_mailitems_sp	Deletes email messages sent by all users from the Database Mail internal tables.

Sending email messages using Database Mail

You use the [sp_send_dbmail](#) stored procedure to send email messages using Database Mail.

Usage

```
EXEC msdb.dbo.sp_send_dbmail
@profile_name = 'profile_name',
@recipients = 'recipient1@example.com[; recipient2; ... recipientn]',
@subject = 'subject',
@body = 'message_body',
[@body_format = 'HTML'],
[@file_attachments = 'file_path1; file_path2; ... file_pathn'],
[@query = 'SQL_query'],
[@attach_query_result_as_file = 0/1]';
```

The following parameters are required:

- `@profile_name` – The name of the Database Mail profile from which to send the message.
- `@recipients` – The semicolon-delimited list of email addresses to which to send the message.
- `@subject` – The subject of the message.
- `@body` – The body of the message. You can also use a declared variable as the body.

The following parameters are optional:

- `@body_format` – This parameter is used with a declared variable to send email in HTML format.
- `@file_attachments` – The semicolon-delimited list of message attachments. File paths must be absolute paths.
- `@query` – A SQL query to run. The query results can be attached as a file or included in the body of the message.
- `@attach_query_result_as_file` – Whether to attach the query result as a file. Set to 0 for no, 1 for yes. The default is 0.

Examples

The following examples demonstrate how to send email messages.

Example of sending a message to a single recipient

```
USE msdb
GO

EXEC msdb.dbo.sp_send_dbmail
    @profile_name      = 'Notifications',
    @recipients        = 'nobody@example.com',
    @subject           = 'Automated DBMail message - 1',
    @body               = 'Database Mail configuration was successful.';
GO
```

Example of sending a message to multiple recipients

```
USE msdb
GO
```

```
EXEC msdb.dbo.sp_send_dbmail
    @profile_name      = 'Notifications',
    @recipients        = 'recipient1@example.com;recipient2@example.com',
    @subject           = 'Automated DBMail message - 2',
    @body               = 'This is a message.';
GO
```

Example of sending a SQL query result as a file attachment

```
USE msdb
GO

EXEC msdb.dbo.sp_send_dbmail
    @profile_name      = 'Notifications',
    @recipients        = 'nobody@example.com',
    @subject           = 'Test SQL query',
    @body               = 'This is a SQL query test.',
    @query              = 'SELECT * FROM abc.dbo.test',
    @attach_query_result_as_file = 1;
GO
```

Example of sending a message in HTML format

```
USE msdb
GO

DECLARE @HTML_Body as NVARCHAR(500) = 'Hi, <h4> Heading </h4> <br> See the report. <b>
Regards </b>';

EXEC msdb.dbo.sp_send_dbmail
    @profile_name      = 'Notifications',
    @recipients        = 'nobody@example.com',
    @subject           = 'Test HTML message',
    @body               = @HTML_Body,
    @body_format       = 'HTML';
GO
```

Example of sending a message using a trigger when a specific event occurs in the database

```
USE AdventureWorks2017
GO
IF OBJECT_ID ('Production.iProductNotification', 'TR') IS NOT NULL
DROP TRIGGER Purchasing.iProductNotification
GO

CREATE TRIGGER iProductNotification ON Production.Product
    FOR INSERT
    AS
    DECLARE @ProductInformation nvarchar(255);
    SELECT
        @ProductInformation = 'A new product, ' + Name + ', is now available for $' +
        CAST(StandardCost AS nvarchar(20)) + '!'
    FROM INSERTED i;

EXEC msdb.dbo.sp_send_dbmail
    @profile_name      = 'Notifications',
    @recipients        = 'nobody@example.com',
    @subject           = 'New product information',
    @body               = @ProductInformation;
GO
```

Viewing messages, logs, and attachments

You use RDS stored procedures to view messages, event logs, and attachments.

To view all email messages

- Use the following SQL query.

```
SELECT * FROM msdb.dbo.rds_fn_sysmail_allitems(); --WHERE sent_status='sent' or  
'failed' or 'unsent'
```

To view all email event logs

- Use the following SQL query.

```
SELECT * FROM msdb.dbo.rds_fn_sysmail_event_log();
```

To view all email attachments

- Use the following SQL query.

```
SELECT * FROM msdb.dbo.rds_fn_sysmail_mailattachments();
```

Deleting messages

You use the `rds_sysmail_delete_mailitems_sp` stored procedure to delete messages.

Note

RDS automatically deletes mail table items when DBMail history data reaches 1 GB in size, with a retention period of at least 24 hours.

If you want to keep mail items for a longer period, you can archive them. For more information, see [Create a SQL Server Agent job to archive Database Mail messages and event logs](#) in the Microsoft documentation.

To delete all email messages

- Use the following SQL statement.

```
DECLARE @GETDATE datetime  
SET @GETDATE = GETDATE();  
EXECUTE msdb.dbo.rds_sysmail_delete_mailitems_sp @sent_before = @GETDATE;  
GO
```

To delete all email messages with a particular status

- Use the following SQL statement to delete all failed messages.

```
DECLARE @GETDATE datetime  
SET @GETDATE = GETDATE();  
EXECUTE msdb.dbo.rds_sysmail_delete_mailitems_sp @sent_status = 'failed';  
GO
```

Starting the mail queue

You use the `rds_sysmail_control` stored procedure to start the Database Mail process.

Note

Enabling Database Mail automatically starts the mail queue.

To start the mail queue

- Use the following SQL statement.

```
EXECUTE msdb.dbo.rds_sysmail_control start;
GO
```

Stopping the mail queue

You use the `rds_sysmail_control` stored procedure to stop the Database Mail process.

To stop the mail queue

- Use the following SQL statement.

```
EXECUTE msdb.dbo.rds_sysmail_control stop;
GO
```

Working with file attachments

The following file attachment extensions aren't supported in Database Mail messages from RDS on SQL Server: .ade, .adp, .apk, .appx, .appxbundle, .bat, .bak, .cab, .chm, .cmd, .com, .cpl, .dll, .dmg, .exe, .hta, .inf1, .ins, .isp, .is, and .wsh.

Database Mail uses the Microsoft Windows security context of the current user to control access to files. Users who log in with SQL Server Authentication can't attach files using the `@file_attachments` parameter with the `sp_send_dbmail` stored procedure. Windows doesn't allow SQL Server to provide credentials from a remote computer to another remote computer. Therefore, Database Mail can't attach files from a network share when the command is run from a computer other than the computer running SQL Server.

However, you can use SQL Server Agent jobs to attach files. For more information on SQL Server Agent, see [Using SQL Server Agent \(p. 822\)](#) and [SQL Server Agent](#) in the Microsoft documentation.

Considerations for Multi-AZ deployments

When you configure Database Mail on a Multi-AZ DB instance, the configuration isn't automatically propagated to the secondary. We recommend converting the Multi-AZ instance to a Single-AZ instance, configuring Database Mail, and then converting the DB instance back to Multi-AZ. Then both the primary and secondary nodes have the Database Mail configuration.

If you create a read replica from your Multi-AZ instance that has Database Mail configured, the replica inherits the configuration, but without the password to the SMTP server. Update the Database Mail account with the password.

Instance store support for the tempdb database on Amazon RDS for SQL Server

An *instance store* provides temporary block-level storage for your DB instance. This storage is located on disks that are physically attached to the host computer. These disks have Non-Volatile Memory Express (NVMe) instance storage that is based on solid-state drives (SSDs). This storage is optimized for low latency, very high random I/O performance, and high sequential read throughput.

By placing tempdb data files and tempdb log files on the instance store, you can achieve lower read and write latencies compared to standard storage based on Amazon EBS.

Note

SQL Server database files and database log files aren't placed on the instance store.

Enabling the instance store

When RDS provisions DB instances with one of the following instance classes, the tempdb database is automatically placed onto the instance store:

- db.m5d
- db.r5d

To enable the instance store, do one of the following:

- Create a SQL Server DB instance using one of these instance types. For more information, see [Creating an Amazon RDS DB instance \(p. 141\)](#).
- Modify an existing SQL Server DB instance to use one of them. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

The instance store is available in all AWS Regions where one or more of these instance types are supported. For more information on the db.m5d and db.r5d instance classes, see [DB instance classes \(p. 7\)](#). For more information on the instance classes supported by Amazon RDS for SQL Server, see [DB instance class support for Microsoft SQL Server \(p. 634\)](#).

File location and size considerations

On instances without an instance store, RDS stores the tempdb data and log files in the D:\rdsdbdata\DATA directory. Both files start at 8 MB by default.

On instances with an instance store, RDS stores the tempdb data and log files in the T:\rdsdbdata\DATA directory.

When tempdb has only one data file (tempdb.mdf) and one log file (templog.ldf), templog.ldf starts at 8 MB by default and tempdb.mdf starts at 80% or more of the instance's storage capacity. Twenty percent of the storage capacity or 200 GB, whichever is less, is kept free to start. Multiple tempdb data files split the 80% disk space evenly, while log files always have an 8-MB initial size.

For example, if you modify your DB instance class from db.m5.2xlarge to db.m5d.2xlarge, the size of tempdb data files increases from 8 MB each to 234 GB in total.

Note

Besides the tempdb data and log files on the instance store (T:\rdsdbdata\DATA), you can still create extra tempdb data and log files on the data volume (D:\rdsdbdata\DATA). Those files always have an 8 MB initial size.

Backup considerations

You might need to retain backups for long periods, incurring costs over time. The `tempdb` data and log blocks can change very often depending on the workload. This can greatly increase the DB snapshot size.

When `tempdb` is on the instance store, snapshots don't include temporary files. This means that snapshot sizes are smaller and consume less of the free backup allocation compared to EBS-only storage.

Disk full errors

If you use all of the available space in the instance store, you might receive errors such as the following:

- The transaction log for database 'tempdb' is full due to 'ACTIVE_TRANSACTION'.
- Could not allocate space for object 'dbo.SORT temporary run storage: 140738941419520' in database 'tempdb' because the 'PRIMARY' filegroup is full. Create disk space by deleting unneeded files, dropping objects in the filegroup, adding additional files to the filegroup, or setting autogrowth on for existing files in the filegroup.

You can do one or more of the following when the instance store is full:

- Adjust your workload or the way you use `tempdb`.
- Scale up to use a DB instance class with more NVMe storage.
- Stop using the instance store, and use an instance class with only EBS storage.
- Use a mixed mode by adding secondary data or log files for `tempdb` on the EBS volume.

Removing the instance store

To remove the instance store, modify your SQL Server DB instance to use an instance type that doesn't support instance store, such as `db.m5` or `db.r5`.

Note

When you remove the instance store, the temporary files are moved to the `D:\rdsdbdata\DATA` directory and reduced in size to 8 MB.

Using extended events with Amazon RDS for Microsoft SQL Server

You can use extended events in Microsoft SQL Server to capture debugging and troubleshooting information for Amazon RDS for SQL Server. Extended events replace SQL Trace and Server Profiler, which have been deprecated by Microsoft. Extended events are similar to profiler traces but with more granular control on the events being traced. Extended events are supported for SQL Server versions 2012 and later on Amazon RDS. For more information, see [Extended events overview](#) in the Microsoft documentation.

Extended events are turned on automatically for users with master user privileges in Amazon RDS for SQL Server.

Topics

- [Limitations and recommendations \(p. 746\)](#)
- [Configuring extended events on RDS for SQL Server \(p. 746\)](#)
- [Considerations for Multi-AZ deployments \(p. 747\)](#)
- [Querying extended event files \(p. 748\)](#)

Limitations and recommendations

When using extended events on RDS for SQL Server, the following limitations apply:

- Extended events are supported only for the Enterprise and Standard Editions.
- You can't alter default extended event sessions.
- Make sure to set the session memory partition mode to `NONE`.
- Session event retention mode can be either `ALLOW_SINGLE_EVENT_LOSS` or `ALLOW_MULTIPLE_EVENT_LOSS`.
- Event Tracing for Windows (ETW) targets aren't supported.
- Make sure that file targets are in the `D:\rdsdbdata\log` directory.
- For pair matching targets, set the `respond_to_memory_pressure` property to 1.
- Ring buffer target memory can't be greater than 4 MB.
- The following actions aren't supported:
 - `debug_break`
 - `create_dump_all_threads`
 - `create_dump_single_threads`
- The `rpc_completed` event is supported on the following versions and later: 15.0.4083.2, 14.0.3370.1, 13.0.5865.1, 12.0.6433.1, 11.0.7507.2.

Configuring extended events on RDS for SQL Server

On RDS for SQL Server, you can configure the values of certain parameters of extended event sessions. The following table describes the configurable parameters.

Parameter name	Description
<code>xe_session_max_memory</code>	Specifies the maximum amount
<code>xe_session_max_event_size</code>	Specifies the maximum memory

Parameter name	Description
<code>xe_session_max_dispatch_latency</code>	Specifies the amount of time that the event session.
<code>xe_file_target_size</code>	Specifies the maximum size of the .xel file.
<code>xe_file_retention</code>	Specifies the retention time in days.

Note

Setting `xe_file_retention` to zero causes .xel files to be removed automatically after the lock on these files is released by SQL Server. The lock is released whenever an .xel file reaches the size limit set in `xe_file_target_size`.

You can use the `rdsadmin.dbo.rds_show_configuration` stored procedure to show the current values of these parameters. For example, use the following SQL statement to view the current setting of `xe_session_max_memory`.

```
exec rdsadmin..rds_show_configuration 'xe_session_max_memory'
```

You can use the `rdsadmin.dbo.rds_set_configuration` stored procedure to modify them. For example, use the following SQL statement to set `xe_session_max_memory` to 4 MB.

```
exec rdsadmin..rds_set_configuration 'xe_session_max_memory', 4
```

Considerations for Multi-AZ deployments

When you create an extended event session on a primary DB instance, it doesn't propagate to the standby replica. You can fail over and create the extended event session on the new primary DB instance. Or you can remove and then re-add the Multi-AZ configuration to propagate the extended event session to the standby replica. RDS stops all nondefault extended event sessions on the standby replica, so that these sessions don't consume resources on the standby. Because of this, after a standby replica becomes the primary DB instance, make sure to manually start the extended event sessions on the new primary.

Note

This approach applies to both Always On Availability Groups and Database Mirroring.

You can also use a SQL Server Agent job to track the standby replica and start the sessions if the standby becomes the primary. For example, use the following query in your SQL Server Agent job step to restart event sessions on a primary DB instance.

```
BEGIN
    IF (DATABASEPROPERTYEX('rdsadmin','Updateability')='READ_WRITE'
        AND DATABASEPROPERTYEX('rdsadmin','status')='ONLINE'
        AND (DATABASEPROPERTYEX('rdsadmin','Collation') IS NOT NULL OR
        DATABASEPROPERTYEX('rdsadmin','IsAutoClose')=1)
    )
    BEGIN
        IF NOT EXISTS (SELECT 1 FROM sys.dm_xe_sessions WHERE name='xe1')
            ALTER EVENT SESSION xe1 ON SERVER STATE=START
        IF NOT EXISTS (SELECT 1 FROM sys.dm_xe_sessions WHERE name='xe2')
            ALTER EVENT SESSION xe2 ON SERVER STATE=START
    END
END
```

This query restarts the event sessions `xe1` and `xe2` on a primary DB instance if these sessions are in a stopped state. You can also add a schedule with a convenient interval to this query.

Querying extended event files

You can either use SQL Server Management Studio or the `sys.fn_xe_file_target_read_file` function to view data from extended events that use file targets. For more information on this function, see [sys.fn_xe_file_target_read_file \(Transact-SQL\)](#) in the Microsoft documentation.

Extended event file targets can only write files to the `D:\rdsdbdata\log` directory on RDS for SQL Server.

As an example, use the following SQL query to list the contents of all files of extended event sessions whose names start with `xe`.

```
SELECT * FROM sys.fn_xe_file_target_read_file('d:\rdsdbdata\log\xe*', null,null,null);
```

Options for the Microsoft SQL Server database engine

In this section, you can find descriptions for options that are available for Amazon RDS instances running the Microsoft SQL Server DB engine. To enable these options, you add them to an option group, and then associate the option group with your DB instance. For more information, see [Working with option groups \(p. 212\)](#).

If you're looking for optional features that aren't added through RDS option groups (such as SSL, Microsoft Windows Authentication, and Amazon S3 integration), see [Additional features for Microsoft SQL Server on Amazon RDS \(p. 703\)](#).

Amazon RDS supports the following options for Microsoft SQL Server DB instances.

Option	Option ID	Engine editions
Native backup and restore (p. 751)	SQLSERVER_BACKUP_RESTORE	SQL Server Enterprise Edition SQL Server Standard Edition SQL Server Web Edition SQL Server Express Edition
Transparent Data Encryption (p. 754)	TRANSPARENT_DATA_ENCRYPTION (RDS console) TDE (AWS CLI and RDS API)	SQL Server 2012–2019 Enterprise Edition SQL Server 2019 Standard Edition
SQL Server Audit (p. 757)	SQLSERVER_AUDIT	In RDS, starting with SQL Server 2012, all editions of SQL Server support server-level audits, and Enterprise Edition also supports database-level audits. Starting with SQL Server SQL Server 2016 (13.x) SP1, all editions support both server-level and database-level audits. For more information, see SQL Server Audit (database engine) in the SQL Server documentation.
SQL Server Analysis Services (p. 762)	SSAS	SQL Server Enterprise Edition

Option	Option ID	Engine editions
		SQL Server Standard Edition
SQL Server Integration Services (p. 773)	SSIS	SQL Server Enterprise Edition
		SQL Server Standard Edition
SQL Server Reporting Services (p. 787)	SSRS	SQL Server Enterprise Edition
		SQL Server Standard Edition
Microsoft Distributed Transaction Coordinator (p. 797)	MSDTC	In RDS, starting with SQL Server 2012, all editions of SQL Server support distributed transactions.

Listing the available options for SQL Server versions and editions

You can use the `describe-option-group-options` AWS CLI command to list the available options for SQL Server versions and editions, and the settings for those options.

The following example shows the options and option settings for SQL Server 2019 Enterprise Edition. The `--engine-name` option is required.

```
aws rds describe-option-group-options --engine-name sqlserver-ee --major-engine-version 15.00
```

The output resembles the following:

```
{
    "OptionGroupOptions": [
        {
            "Name": "MSDTC",
            "Description": "Microsoft Distributed Transaction Coordinator",
            "EngineName": "sqlserver-ee",
            "MajorEngineVersion": "15.00",
            "MinimumRequiredMinorEngineVersion": "4043.16.v1",
            "PortRequired": true,
            "DefaultPort": 5000,
            "OptionsDependedOn": [],
            "OptionsConflictsWith": [],
            "Persistent": false,
            "Permanent": false,
            "RequiresAutoMinorEngineVersionUpgrade": false,
            "VpcOnly": false,
            "OptionGroupOptionSettings": [
                {
                    "SettingName": "ENABLE_SNA_LU",
                    "SettingDescription": "able support for SNA LU protocol",
                    "DefaultValue": "true",
                    "Value": "true"
                }
            ]
        }
    ]
}
```

```
        "ApplyType": "DYNAMIC",
        "AllowedValues": "true,false",
        "IsModifiable": true,
        "IsRequired": false,
        "MinimumEngineVersionPerAllowedValue": []
    },
    ...
{
    "Name": "TDE",
    "Description": "SQL Server - Transparent Data Encryption",
    "EngineName": "sqlserver-ee",
    "MajorEngineVersion": "15.00",
    "MinimumRequiredMinorEngineVersion": "4043.16.v1",
    "PortRequired": false,
    "OptionsDependedOn": [],
    "OptionsConflictsWith": [],
    "Persistent": true,
    "Permanent": false,
    "RequiresAutoMinorEngineVersionUpgrade": false,
    "VpcOnly": false,
    "OptionGroupOptionSettings": []
}
]
```

Support for native backup and restore in SQL Server

By using native backup and restore for SQL Server databases, you can create a differential or full backup of your on-premises database and store the backup files on Amazon S3. You can then restore to an existing Amazon RDS DB instance running SQL Server. You can also back up an RDS for SQL Server database, store it on Amazon S3, and restore it in other locations. In addition, you can restore the backup to an on-premises server, or a different Amazon RDS DB instance running SQL Server. For more information, see [Importing and exporting SQL Server databases \(p. 671\)](#).

Amazon RDS supports native backup and restore for Microsoft SQL Server databases by using differential and full backup files (.bak files).

Adding the native backup and restore option

The general process for adding the native backup and restore option to a DB instance is the following:

1. Create a new option group, or copy or modify an existing option group.
2. Add the `SQLSERVER_BACKUP_RESTORE` option to the option group.
3. Associate an AWS Identity and Access Management (IAM) role with the option. The IAM role must have access to an S3 bucket to store the database backups.

That is, it must have as its option setting a valid Amazon Resource Name (ARN) in the format `arn:aws:iam::account-id:role/role-name`. For more information, see [Amazon Resource Names \(ARNs\) in the AWS General Reference](#).

4. Associate the option group with the DB instance.

After you add the native backup and restore option, you don't need to restart your DB instance. As soon as the option group is active, you can begin backing up and restoring immediately.

Console

To add the native backup and restore option

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Create a new option group or use an existing option group. For information on how to create a custom DB option group, see [Creating an option group \(p. 214\)](#).
To use an existing option group, skip to the next step.
4. Add the **SQLSERVER_BACKUP_RESTORE** option to the option group. For more information about adding options, see [Adding an option to an option group \(p. 216\)](#).
5. Do one of the following:
 - To use an existing IAM role and Amazon S3 settings, choose an existing IAM role for **IAM Role**. If you use an existing IAM role, RDS uses the Amazon S3 settings configured for this role.
 - To create a new role and configure new Amazon S3 settings, do the following:
 1. For **IAM Role**, choose [Create a New Role](#).
 2. For **Select S3 Bucket**, either create an S3 bucket or use an existing one. To create a new bucket, choose [Create a New S3 Bucket](#). To use an existing bucket, choose it from the list.
 3. For **S3 folder path prefix (optional)**, specify a prefix to use for the files stored in your Amazon S3 bucket.

This prefix can include a file path but doesn't have to. If you provide a prefix, RDS attaches that prefix to all backup files. RDS then uses the prefix during a restore to identify related files and ignore irrelevant files. For example, you might use the S3 bucket for purposes besides holding backup files. In this case, you can use the prefix to have RDS perform native backup and restore only on a particular folder and its subfolders.

If you leave the prefix blank, then RDS doesn't use a prefix to identify backup files or files to restore. As a result, during a multiple-file restore, RDS attempts to restore every file in every folder of the S3 bucket.

4. For **Enable Encryption**, choose **Yes** to encrypt the backup file. Choose **No** to leave the backup file unencrypted.

If you choose **Yes**, choose an encryption key for **Master Key**. For more information about encryption keys, see [Getting started in the AWS Key Management Service Developer Guide](#).

6. Choose **Add option**.
7. Apply the option group to a new or existing DB instance:
 - For a new DB instance, apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance \(p. 141\)](#).
 - For an existing DB instance, apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

CLI

This procedure makes the following assumptions:

- You're adding the **SQLSERVER_BACKUP_RESTORE** option to an option group that already exists. For more information about adding options, see [Adding an option to an option group \(p. 216\)](#).
- You're associating the option with an IAM role that already exists and has access to an S3 bucket to store the backups.

- You're applying the option group to a DB instance that already exists. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

To add the native backup and restore option

1. Add the `SQLSERVER_BACKUP_RESTORE` option to the option group.

Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
--apply-immediately \
--option-group-name mybackupgroup \
--options "OptionName=SQLSERVER_BACKUP_RESTORE, \
OptionSettings=[{Name=IAM_ROLE_ARN,Value=arn:aws:iam::account-id:role/role-name}]"
```

For Windows:

```
aws rds add-option-to-option-group ^
--option-group-name mybackupgroup ^
--options "[{\\"OptionName\\": \\"SQLSERVER_BACKUP_RESTORE\\\", ^
\\\"OptionSettings\\\": [{\\\"Name\\\": \\"IAM_ROLE_ARN\\\", ^
\\\"Value\\\": \\"arn:aws:iam::account-id:role/role-name\"}]}]" ^
--apply-immediately
```

Note

When using the Windows command prompt, you must escape double quotes ("") in JSON code by prefixing them with a backslash (\).

2. Apply the option group to the DB instance.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--option-group-name mybackupgroup \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--option-group-name mybackupgroup ^
--apply-immediately
```

Modifying native backup and restore option settings

After you enable the native backup and restore option, you can modify the settings for the option. For more information about how to modify option settings, see [Modifying an option setting \(p. 221\)](#).

Removing the native backup and restore option

You can turn off native backup and restore by removing the option from your DB instance. After you remove the native backup and restore option, you don't need to restart your DB instance.

To remove the native backup and restore option from a DB instance, do one of the following:

- Remove the option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group \(p. 224\)](#).
- Modify the DB instance and specify a different option group that doesn't include the native backup and restore option. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

Support for Transparent Data Encryption in SQL Server

Amazon RDS supports using Transparent Data Encryption (TDE) to encrypt stored data on your DB instances running Microsoft SQL Server. TDE automatically encrypts data before it is written to storage, and automatically decrypts data when the data is read from storage.

Amazon RDS supports TDE for the following SQL Server versions and editions:

- SQL Server 2019 Standard and Enterprise Editions
- SQL Server 2017 Enterprise Edition
- SQL Server 2016 Enterprise Edition
- SQL Server 2014 Enterprise Edition
- SQL Server 2012 Enterprise Edition

Transparent Data Encryption for SQL Server provides encryption key management by using a two-tier key architecture. A certificate, which is generated from the database master key, is used to protect the data encryption keys. The database encryption key performs the actual encryption and decryption of data on the user database. Amazon RDS backs up and manages the database master key and the TDE certificate.

Note

RDS doesn't support exporting TDE certificates.

Transparent Data Encryption is used in scenarios where you need to encrypt sensitive data. For example, you might want to provide data files and backups to a third party, or address security-related regulatory compliance issues. You can't encrypt the system databases for SQL Server, such as the `model` or `master` databases.

Note

You can create native backups of TDE-enabled databases, but you can't restore those backups to on-premises databases.

A detailed discussion of Transparent Data Encryption is beyond the scope of this guide, but you should understand the security strengths and weaknesses of each encryption algorithm and key. For information about Transparent Data Encryption for SQL Server, see [Transparent Data Encryption \(TDE\)](#) on the Microsoft website.

Enabling TDE

To enable Transparent Data Encryption for an RDS for SQL Server DB instance, specify the TDE option in an RDS option group that is associated with that DB instance.

1. Determine whether your DB instance is already associated with an option group that has the TDE option. To view the option group that a DB instance is associated with, you can use the RDS console, the `describe-db-instance` AWS CLI command, or the API operation `DescribeDBInstances`.
2. If the DB instance isn't associated with an option group that has TDE enabled, you have two choices. You can create an option group and add the TDE option, or you can modify the associated option group to add it.

Note

In the RDS console, the option is named `TRANSPARENT_DATA_ENCRYPTION`. In the AWS CLI and RDS API, it's named `TDE`.

For information about creating or modifying an option group, see [Working with option groups \(p. 212\)](#). For information about adding an option to an option group, see [Adding an option to an option group \(p. 216\)](#).

3. Associate the DB instance with the option group that has the TDE option. For information about associating a DB instance with an option group, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

Encrypting data

When the TDE option is added to an option group, Amazon RDS generates a certificate that is used in the encryption process. You can then use the certificate to run SQL statements that encrypt data in a database on the DB instance. The following example uses the RDS-created certificate called `RDSTDECertificateName` to encrypt a database called `customerDatabase`.

```
----- Enabling TDE -----  
  
-- Find a RDSTDECertificate to use  
USE [master]  
GO  
SELECT name FROM sys.certificates WHERE name LIKE 'RDSTDECertificate%'  
GO  
  
USE [customerDatabase]  
GO  
-- Create DEK using one of the certificates from the previous step  
CREATE DATABASE ENCRYPTION KEY  
WITH ALGORITHM = AES_128  
ENCRYPTION BY SERVER CERTIFICATE [RDSTDECertificateName]  
GO  
  
-- Enable encryption on the database  
ALTER DATABASE [customerDatabase]  
SET ENCRYPTION ON  
GO  
  
-- Verify that the database is encrypted  
USE [master]  
GO  
SELECT name FROM sys.databases WHERE is_encrypted = 1  
GO  
SELECT db_name(database_id) as DatabaseName, * FROM sys.dm_database_encryption_keys  
GO
```

The time that it takes to encrypt a SQL Server database using TDE depends on several factors. These include the size of the DB instance, whether PIOPS is enabled for the instance, the amount of data, and other factors.

Option group considerations

The TDE option is a persistent option that you can't remove from an option group unless all DB instances and backups are disassociated from the option group. After you add the TDE option to an option group, the option group can only be associated with DB instances that use TDE. For more information about persistent options in an option group, see [Option groups overview \(p. 212\)](#).

Because the TDE option is a persistent option, you can have a conflict between the option group and an associated DB instance. You can have a conflict between the option group and an associated DB instance in the following situations:

- The current option group has the TDE option, and you replace it with an option group that does not have the TDE option.
- You restore from a DB snapshot to a new DB instance that does not have an option group that contains the TDE option. For more information about this scenario, see [Option group considerations \(p. 356\)](#).

SQL Server performance considerations

The performance of a SQL Server DB instance can be impacted by using Transparent Data Encryption.

Performance for unencrypted databases can also be degraded if the databases are on a DB instance that has at least one encrypted database. As a result, we recommend that you keep encrypted and unencrypted databases on separate DB instances.

Because of the nature of encryption, the database size and the size of the transaction log is larger than for an unencrypted database. You could run over your allocation of free backup space. The nature of TDE causes an unavoidable performance hit. If you need high performance and TDE, measure the impact and make sure that it meets your needs. There is less of an impact on performance if you use Provisioned IOPS and at least an M3.Large DB instance class.

Disabling TDE

To disable TDE for a DB instance, first make sure that there are no encrypted objects left on the DB instance by either decrypting the objects or by dropping them. If any encrypted objects exist on the DB instance, you can't disable TDE for the DB instance. When you use the console to remove the TDE option from an option group, the console indicates that it is processing. In addition, an error event is created if the option group is associated with an encrypted DB instance or DB snapshot.

The following example removes the TDE encryption from a database called `customerDatabase`.

```
----- Removing TDE -----  
  
USE [customerDatabase]  
GO  
  
-- Disable encryption on the database  
ALTER DATABASE [customerDatabase]  
SET ENCRYPTION OFF  
GO  
  
-- Wait until the encryption state of the database becomes 1. The state is 5 (Decryption in progress) for a while
```

```
SELECT db_name(database_id) as DatabaseName, * FROM sys.dm_database_encryption_keys
GO

-- Drop the DEK used for encryption
DROP DATABASE ENCRYPTION KEY
GO

-- Alter to SIMPLE Recovery mode so that your encrypted log gets truncated
USE [master]
GO
ALTER DATABASE [customerDatabase] SET RECOVERY SIMPLE
GO
```

When all objects are decrypted, you can have two options. You can modify the DB instance to be associated with an option group without the TDE option. Or you can remove the TDE option from the option group.

SQL Server Audit

In Amazon RDS, you can audit Microsoft SQL Server databases by using the built-in SQL Server auditing mechanism. You can create audits and audit specifications in the same way that you create them for on-premises database servers.

RDS uploads the completed audit logs to your S3 bucket, using the IAM role that you provide. If you enable retention, RDS keeps your audit logs on your DB instance for the configured period of time.

For more information, see [SQL Server Audit \(database engine\)](#) in the Microsoft SQL Server documentation.

Topics

- [Support for SQL Server Audit \(p. 757\)](#)
- [Adding SQL Server Audit to the DB instance options \(p. 758\)](#)
- [Using SQL Server Audit \(p. 759\)](#)
- [Viewing audit logs \(p. 760\)](#)
- [Using SQL Server Audit with Multi-AZ instances \(p. 760\)](#)
- [Configuring an S3 bucket \(p. 761\)](#)
- [Manually creating an IAM role for SQL Server Audit \(p. 761\)](#)

Support for SQL Server Audit

In Amazon RDS, starting with SQL Server 2012, all editions of SQL Server support server-level audits, and the Enterprise edition also supports database-level audits. Starting with SQL Server 2016 (13.x) SP1, all editions support both server-level and database-level audits. For more information, see [SQL Server Audit \(database engine\)](#) in the SQL Server documentation.

RDS supports configuring the following option settings for SQL Server Audit.

Option setting	Valid values	Description
IAM_ROLE_ARN	A valid Amazon Resource Name (ARN) in the format <code>arn:aws:iam::account-id:role/role-name</code> .	The ARN of the IAM role that grants access to the S3 bucket where you want to store your audit logs. For more information, see Amazon

Option setting	Valid values	Description
		Resource Names (ARNs) in the AWS General Reference .
S3_BUCKET_ARN	A valid ARN in the format <code>arn:aws:s3:::bucket-name</code> or <code>arn:aws:s3:::bucket-name/key-prefix</code>	The ARN for the S3 bucket where you want to store your audit logs.
ENABLE_COMPRESSION	true or false	Controls audit log compression. By default, compression is enabled (set to true).
RETENTION_TIME	0 to 840	The retention time (in hours) that SQL Server audit records are kept on your RDS instance. By default, retention is disabled.

RDS supports SQL Server Audit in all AWS Regions except Middle East (Bahrain).

Adding SQL Server Audit to the DB instance options

Enabling SQL Server Audit requires two steps: enabling the option on the DB instance, and enabling the feature inside SQL Server. The process for adding the SQL Server Audit option to a DB instance is as follows:

1. Create a new option group, or copy or modify an existing option group.
2. Add and configure all required options.
3. Associate the option group with the DB instance.

After you add the SQL Server Audit option, you don't need to restart your DB instance. As soon as the option group is active, you can create audits and store audit logs in your S3 bucket.

To add and configure SQL Server Audit on a DB instance's option group

1. Choose one of the following:
 - Use an existing option group.
 - Create a custom DB option group and use that option group. For more information, see [Creating an option group \(p. 214\)](#).
2. Add the **SQLSERVER_AUDIT** option to the option group, and configure the option settings. For more information about adding options, see [Adding an option to an option group \(p. 216\)](#).
 - For **IAM role**, if you already have an IAM role with the required policies, you can choose that role. To create a new IAM role, choose **Create a New Role**. For information about the required policies, see [Manually creating an IAM role for SQL Server Audit \(p. 761\)](#).
 - For **Select S3 destination**, if you already have an S3 bucket that you want to use, choose it. To create an S3 bucket, choose **Create a New S3 Bucket**.
 - For **Enable Compression**, leave this option chosen to compress audit files. Compression is enabled by default. To disable compression, clear **Enable Compression**.
 - For **Audit log retention**, to keep audit records on the DB instance, choose this option. Specify a retention time in hours. The maximum retention time is 35 days.
3. Apply the option group to a new or existing DB instance. Choose one of the following:

- If you are creating a new DB instance, apply the option group when you launch the instance.
- On an existing DB instance, apply the option group by modifying the instance and then attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

Modifying the SQL Server Audit option

After you enable the SQL Server Audit option, you can modify the settings. For information about how to modify option settings, see [Modifying an option setting \(p. 221\)](#).

Removing SQL Server Audit from the DB instance options

You can turn off the SQL Server Audit feature by disabling audits and then deleting the option.

To remove auditing

1. Disable all of the audit settings inside SQL Server. To learn where audits are running, query the SQL Server security catalog views. For more information, see [Security catalog views](#) in the Microsoft SQL Server documentation.
2. Delete the SQL Server Audit option from the DB instance. Choose one of the following:
 - Delete the SQL Server Audit option from the option group that the DB instance uses. This change affects all DB instances that use the same option group. For more information, see [Removing an option from an option group \(p. 224\)](#).
 - Modify the DB instance, and then choose an option group without the SQL Server Audit option. This change affects only the DB instance that you modify. You can specify the default (empty) option group, or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).
3. After you delete the SQL Server Audit option from the DB instance, you don't need to restart the instance. Remove unneeded audit files from your S3 bucket.

Using SQL Server Audit

You can control server audits, server audit specifications, and database audit specifications the same way that you control them for on-premises database servers.

Creating audits

You create server audits in the same way that you create them for on-premises database servers. For information about how to create server audits, see [CREATE SERVER AUDIT](#) in the Microsoft SQL Server documentation.

To avoid errors, adhere to the following limitations:

- Don't exceed the maximum number of supported server audits per instance of 50.
- Instruct SQL Server to write data to a binary file.
- Don't use RDS_ as a prefix in the server audit name.
- For FILEPATH, specify D:\rdsdbdata\SQLAudit.
- For MAXSIZE, specify a size between 2 MB and 50 MB.
- Don't configure MAX_ROLLOVER_FILES or MAX_FILES.
- Don't configure SQL Server to shut down the DB instance if it fails to write the audit record.

Creating audit specifications

You create server audit specifications and database audit specifications the same way that you create them for on-premises database servers. For information about creating audit specifications, see [CREATE SERVER AUDIT SPECIFICATION](#) and [CREATE DATABASE AUDIT SPECIFICATION](#) in the Microsoft SQL Server documentation.

To avoid errors, don't use `RDS_` as a prefix in the name of the database audit specification or server audit specification.

Viewing audit logs

Your audit logs are stored in `D:\rdsdbdata\SQLAudit`.

After SQL Server finishes writing to an audit log file—when the file reaches its size limit—Amazon RDS uploads the file to your S3 bucket. If retention is enabled, Amazon RDS moves the file into the retention folder: `D:\rdsdbdata\SQLAudit\transmitted`.

For information about configuring retention, see [Adding SQL Server Audit to the DB instance options \(p. 758\)](#).

Audit records are kept on the DB instance until the audit log file is uploaded. You can view the audit records by running the following command.

```
SELECT *
FROM msdb.dbo.rds_fn_get_audit_file
  ('D:\rdsdbdata\SQLAudit\*.sqlaudit'
  , default
  , default )
```

You can use the same command to view audit records in your retention folder by changing the filter to `D:\rdsdbdata\SQLAudit\transmitted*.sqlaudit`.

```
SELECT *
FROM msdb.dbo.rds_fn_get_audit_file
  ('D:\rdsdbdata\SQLAudit\transmitted\*.sqlaudit'
  , default
  , default )
```

Using SQL Server Audit with Multi-AZ instances

For Multi-AZ instances, the process for sending audit log files to Amazon S3 is similar to the process for Single-AZ instances. However, there are some important differences:

- Database audit specification objects are replicated to all nodes.
- Server audits and server audit specifications aren't replicated to secondary nodes. Instead, you have to create or modify them manually.

To capture server audits or a server audit specification from both nodes:

1. Create a server audit or a server audit specification on the primary node.
2. Fail over to the secondary node and create a server audit or a server audit specification with the same name and GUID on the secondary node. Use the `AUDIT_GUID` parameter to specify the GUID.

Configuring an S3 bucket

The audit log files are automatically uploaded from the DB instance to your S3 bucket. The following restrictions apply to the S3 bucket that you use as a target for audit files:

- It must be in the same AWS Region as the DB instance.
- It must not be open to the public.
- It can't use [S3 Object Lock](#).
- The bucket owner must also be the IAM role owner.

The target key that is used to store the data follows this naming schema: `bucket-name/key-prefix/instance-name/audit-name/node_file-name.ext`

Note

You set both the bucket name and the key prefix values with the (`s3_BUCKET_ARN`) option setting.

The schema is composed of the following elements:

- **bucket-name** – The name of your S3 bucket.
- **key-prefix** – The custom key prefix you want to use for audit logs.
- **instance-name** – The name of your Amazon RDS instance.
- **audit-name** – The name of the audit.
- **node** – The identifier of the node that is the source of the audit logs (`node1` or `node2`). There is one node for a Single-AZ instance and two replication nodes for a Multi-AZ instance. These are not primary and secondary nodes, because the roles of primary and secondary change over time. Instead, the node identifier is a simple label.
 - **node1** – The first replication node (Single-AZ has one node only).
 - **node2** – The second replication node (Multi-AZ has two nodes).
- **file-name** – The target file name. The file name is taken as-is from SQL Server.
- **ext** – The extension of the file (`zip` or `sqlaudit`):
 - **zip** – If compression is enabled (default).
 - **sqlaudit** – If compression is disabled.

Manually creating an IAM role for SQL Server Audit

Typically, when you create a new option, the AWS Management Console creates the IAM role and the IAM trust policy for you. However, you can manually create a new IAM role to use with SQL Server Audits, so that you can customize it with any additional requirements you might have. To do this, you create an IAM role and delegate permissions so that the Amazon RDS service can use your Amazon S3 bucket. When you create this IAM role, you attach trust and permissions policies. The trust policy allows Amazon RDS to assume this role. The permission policy defines the actions that this role can do. For more information, see [Creating a role to delegate permissions to an AWS service](#) in the *AWS Identity and Access Management User Guide*.

You can use the examples in this section to create the trust and permissions policies you need.

The following example shows a trust policy for SQL Server Audit. The policy uses the *service principal* `rds.amazonaws.com` to allow RDS to write to the S3 bucket. A *service principal* is an identifier that is used to grant permissions to a service. Anytime you allow access to `rds.amazonaws.com` in this way, you are allowing RDS to perform an action on your behalf. For more information about service principals, see [AWS JSON policy elements: Principal](#).

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Principal": {
                "Service": "rds.amazonaws.com"
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

In the following example of a permissions policy for SQL Server Audit, we specify an Amazon Resource Name (ARN) for the Amazon S3 bucket. You can use ARNs to identify a specific account, user, or role that you want grant access to. For more information about using ARNs, see [Amazon resource names \(ARNs\)](#).

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Effect": "Allow",
            "Action": "s3>ListAllMyBuckets",
            "Resource": "*"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3>ListBucket",
                "s3:GetBucketACL",
                "s3:GetBucketLocation"
            ],
            "Resource": "arn:aws:s3:::bucket_name"
        },
        {
            "Effect": "Allow",
            "Action": [
                "s3>PutObject",
                "s3>ListMultipartUploadParts",
                "s3>AbortMultipartUpload"
            ],
            "Resource": "arn:aws:s3:::bucket_name/key_prefix/*"
        }
    ]
}
```

Note

The `s3>ListAllMyBuckets` action is required for verifying that the same AWS account owns both the S3 bucket and the SQL Server DB instance. The action lists the names of the buckets in the account.

S3 bucket namespaces are global. If you accidentally delete your bucket, another user can create a bucket with the same name in a different account. Then the SQL Server Audit data is written to the new bucket.

Support for SQL Server Analysis Services in Amazon RDS for SQL Server

Microsoft SQL Server Analysis Services (SSAS) is part of the Microsoft Business Intelligence (MSBI) suite. SSAS is an online analytical processing (OLAP) and data mining tool that is installed within

SQL Server. You use SSAS to analyze data to help make business decisions. SSAS differs from the SQL Server relational database because SSAS is optimized for queries and calculations common in a business intelligence environment. For more information on SSAS, see the Microsoft [Analysis services documentation](#).

Amazon RDS for SQL Server supports running SQL Server Analysis Services (SSAS) in Tabular mode. You can enable SSAS on existing or new DB instances. It's installed on the same DB instance as your database engine.

RDS supports SSAS for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2019, version 15.00.4043.16.v1 and later
- SQL Server 2017, version 14.00.3223.3.v1 and later
- SQL Server 2016, version 13.00.5426.0.v1 and later

Limitations

The following limitations apply to running SSAS on RDS for SQL Server:

- Tabular is the only supported mode for SSAS.
- Multi-AZ instances aren't supported.
- Instances must use AWS Directory Service for Microsoft Active Directory for SSAS authentication.
- Users aren't given SSAS server administrator access, but they can be granted database-level administrator access.
- The only supported port for accessing SSAS is 2383.
- You can't deploy projects directly. We provide an RDS stored procedure to do this. For more information, see [Deploying SSAS projects on Amazon RDS \(p. 767\)](#).
- Processing during deployment isn't supported.
- Using .xmla files for deployment isn't supported.
- SSAS project input files and database backup output files can only be in the D:\S3 folder on the DB instance.

Enabling SSAS

Use the following process to enable SSAS for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the SSAS option to the option group.
3. Associate the option group with the DB instance.
4. Allow inbound access to the VPC security group for the SSAS listener port.
5. Enable Amazon S3 integration.

Creating the option group for SSAS

Use the AWS Management Console or the AWS CLI to create an option group that corresponds to the SQL Server engine and version of the DB instance that you plan to use.

Note

You can also use an existing option group if it's for the correct SQL Server engine and version.

Console

The following console procedure creates an option group for SQL Server Standard Edition 2017.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** pane, do the following:
 - a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **ssas-se-2017**. The name can contain only letters, digits, and hyphens.
 - b. For **Description**, enter a brief description of the option group, such as **SSAS option group for SQL Server SE 2017**. The description is used for display purposes.
 - c. For **Engine**, choose **sqlserver-se**.
 - d. For **Major engine version**, choose **14.00**.
5. Choose **Create**.

CLI

The following CLI example creates an option group for SQL Server Standard Edition 2017.

To create the option group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds create-option-group \
--option-group-name ssas-se-2017 \
--engine-name sqlserver-se \
--major-engine-version 14.00 \
--option-group-description "SSAS option group for SQL Server SE 2017"
```

For Windows:

```
aws rds create-option-group ^
--option-group-name ssas-se-2017 ^
--engine-name sqlserver-se ^
--major-engine-version 14.00 ^
--option-group-description "SSAS option group for SQL Server SE 2017"
```

Adding the SSAS option to the option group

Next, use the AWS Management Console or the AWS CLI to add the SSAS option to the option group.

Console

To add the SSAS option

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.

3. Choose the option group that you just created.
4. Choose **Add option**.
5. Under **Option details**, choose **SSAS** for **Option name**.
6. Under **Option settings**, enter a value from 10–80 for **Max memory**.

Max memory specifies the upper threshold above which SSAS begins releasing memory more aggressively to make room for requests that are running, and also new high-priority requests. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80, and the default is 45.

Note

The port for accessing SSAS, 2383, is prepopulated.

7. For **Security groups**, choose the VPC security group to associate with the option.
8. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
9. Choose **Add option**.

CLI

To add the SSAS option

1. Create a JSON file, for example `ssas-option.json`, with the following parameters:
 - `OptionGroupName` – The name of option group that you created or chose previously (`ssas-se-2017` in the following example).
 - `Port` – The port that you use to access SSAS. The only supported port is 2383.
 - `VpcSecurityGroupMemberships` – VPC security group memberships for your RDS DB instance.
 - `MAX_MEMORY` – The upper threshold above which SSAS should begin releasing memory more aggressively to make room for requests that are running, and also new high-priority requests. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80, and the default is 45.

```
{
  "OptionGroupName": "ssas-se-2017",
  "OptionsToInclude": [
    {
      "OptionName": "SSAS",
      "Port": 2383,
      "VpcSecurityGroupMemberships" : ["sg-0abcdef123"],
      "OptionSettings": [{"Name" : "MAX_MEMORY", "Value" : "60"}]
    },
    "ApplyImmediately": true
  }
}
```

2. Add the SSAS option to the option group.

Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
  --cli-input-json file://ssas-option.json \
  --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
--cli-input-json file://ssas-option.json ^
--apply-immediately
```

Associating the option group with your DB instance

You can use the AWS Management Console or the AWS CLI to associate the option group with your DB instance.

Console

Associate your option group with a new or existing DB instance:

- For a new DB instance, associate the option group with the DB instance when you launch the instance. For more information, see [Creating an Amazon RDS DB instance \(p. 141\)](#).
- For an existing DB instance, modify the instance and associate the new option group with it. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

Note

If you use an existing instance, it must already have an Active Directory domain and IAM role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see [Using Windows Authentication with an Amazon RDS for SQL Server DB instance \(p. 711\)](#).

CLI

You can associate your option group with a new or existing DB instance.

Note

If you use an existing instance, it must already have an Active Directory domain and IAM role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see [Using Windows Authentication with an Amazon RDS for SQL Server DB instance \(p. 711\)](#).

To create a DB instance that uses the option group

- Specify the same DB engine type and major version that you used when creating the option group.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--db-instance-identifier myssasinstance \
--db-instance-class db.m5.2xlarge \
--engine sqlserver-se \
--engine-version 14.00.3223.3.v1 \
--allocated-storage 100 \
--master-user-password secret123 \
--master-username admin \
--storage-type gp2 \
--license-model li \
--domain-iam-role-name my-directory-iam-role \
--domain my-domain-id \
--option-group-name ssas-se-2017
```

For Windows:

```
aws rds create-db-instance ^
--db-instance-identifier myssasinstance ^
--db-instance-class db.m5.2xlarge ^
--engine sqlserver-se ^
--engine-version 14.00.3223.3.v1 ^
--allocated-storage 100 ^
--master-user-password secret123 ^
--master-username admin ^
--storage-type gp2 ^
--license-model li ^
--domain-iam-role-name my-directory-iam-role ^
--domain my-domain-id ^
--option-group-name ssas-se-2017
```

To modify a DB instance to associate the option group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier myssasinstance \
--option-group-name ssas-se-2017 \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier myssasinstance ^
--option-group-name ssas-se-2017 ^
--apply-immediately
```

Allowing inbound access to your VPC security group

Create an inbound rule for the specified SSAS listener port in the VPC security group associated with your DB instance. For more information about setting up security groups, see [Provide access to your DB instance in your VPC by creating a security group \(p. 70\)](#).

Enabling S3 integration

To download model configuration files to your host for deployment, use S3 integration. For more information, see [Integrating an Amazon RDS for SQL Server DB instance with Amazon S3 \(p. 721\)](#).

Deploying SSAS projects on Amazon RDS

On RDS, you can't deploy SSAS projects directly by using SQL Server Management Studio (SSMS). To deploy projects, use an RDS stored procedure.

Note

Using .xmla files for deployment isn't supported.

Before you deploy projects, make sure of the following:

- S3 integration is enabled. For more information, see [Integrating an Amazon RDS for SQL Server DB instance with Amazon S3 \(p. 721\)](#).

- The Processing Option configuration setting is set to Do Not Process. This setting means that no processing happens after deployment.
- You have both the `myssasproject.asdatabase` and `myssasproject.deploymentoptions` files. They're automatically generated when you build the SSAS project.

To deploy an SSAS project on RDS

1. Download the .asdatabase (SSAS model) file from your S3 bucket to your DB instance, as shown in the following example. For more information on the download parameters, see [Downloading files from an Amazon S3 bucket to a SQL Server DB instance \(p. 727\)](#).

```
exec msdb.dbo.rds_download_from_s3
@s3_arn_of_file='arn:aws:s3:::bucket_name/myssasproject.asdatabase',
[@rds_file_path='D:\S3\imyssasproject.asdatabase'],
[@overwrite_file=1];
```

2. Download the .deploymentoptions file from your S3 bucket to your DB instance.

```
exec msdb.dbo.rds_download_from_s3
@s3_arn_of_file='arn:aws:s3:::bucket_name/myssasproject.deploymentoptions',
[@rds_file_path='D:\S3\imyssasproject.deploymentoptions'],
[@overwrite_file=1];
```

3. Deploy the project.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_DEPLOY_PROJECT',
@file_path='D:\S3\imyssasproject.asdatabase';
```

Monitoring the status of a deployment task

To track the status of your deployment (or download) task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be `NULL` because it doesn't apply to SSAS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to `NULL` and the second parameter to `0`, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,0);
```

To get a specific task, set the first parameter to `NULL` and the second parameter to the task ID, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,42);
```

The `rds_fn_task_status` function returns the following information.

Output parameter	Description
<code>task_id</code>	The ID of the task.
<code>task_type</code>	For SSAS, tasks can have the following task types: <ul style="list-style-type: none"> • <code>SSAS_DEPLOY_PROJECT</code> • <code>SSAS_ADD_DB_ADMIN_MEMBER</code>

Output parameter	Description
	<ul style="list-style-type: none"> • SSAS_BACKUP_DB • SSAS_RESTORE_DB
database_name	Not applicable to SSAS tasks.
% complete	The progress of the task as a percentage.
duration (mins)	The amount of time spent on the task, in minutes.
lifecycle	<p>The status of the task. Possible statuses are the following:</p> <ul style="list-style-type: none"> • CREATED – After you call one of the SSAS stored procedures, a task is created and the status is set to CREATED. • IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS. It can take up to five minutes for the status to change from CREATED to IN_PROGRESS. • SUCCESS – After a task completes, the status is set to SUCCESS. • ERROR – If a task fails, the status is set to ERROR. For more information about the error, see the task_info column. • CANCEL_REQUESTED – After you call rds_cancel_task, the status of the task is set to CANCEL_REQUESTED. • CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED.
task_info	Additional information about the task. If an error occurs during processing, this column contains information about the error.
last_updated	The date and time that the task status was last updated.
created_at	The date and time that the task was created.
S3_object_arn	Not applicable to SSAS tasks.
overwrite_S3_backup_file	Not applicable to SSAS tasks.
KMS_master_key_arn	Not applicable to SSAS tasks.
filepath	Not applicable to SSAS tasks.
overwrite_file	Not applicable to SSAS tasks.
task_metadata	Metadata associated with the SSAS task.

Using SSAS on Amazon RDS

After deploying the SSAS project, you can directly process the OLAP database on SSMS.

To use SSAS on RDS

1. In SSMS, connect to SSAS using the user name and password for the Active Directory domain.
2. Expand **Databases**. The newly deployed SSAS database appears.
3. Expand **Connections**, open the context (right-click) menu for the connection object, and then choose **Properties**.
4. In the connection string, update the user name and password to those for the source SQL database. Doing this is required for processing tables.
5. Open the context (right-click) menu for the SSAS database that you created and choose **Process Database**.

Depending on the size of the input data, the processing operation might take several minutes to complete.

Adding a domain user as a database administrator

You can add a domain user as an SSAS database administrator in the following ways:

- A database administrator can use SSMS to create a role with `admin` privileges, then add users to that role.
- You can use the following stored procedure.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_ADD_DB_ADMIN_MEMBER',
@database_name='myssasdb',
@ssas_role_name='exampleRole',
@ssas_role_member='domain_name\domain_user_name';
```

The following parameters are required:

- `@task_type` – The type of the MSBI task, in this case `SSAS_ADD_DB_ADMIN_MEMBER`.
- `@database_name` – The name of the SSAS database to which you're granting administrator privileges.
- `@ssas_role_name` – The SSAS database administrator role name. If the role doesn't already exist, it's created.
- `@ssas_role_member` – The SSAS database user that you're adding to the administrator role.

Backing up an SSAS database

You can create SSAS database backup files only in the `D:\S3` folder on the DB instance. To move the backup files to your S3 bucket, use Amazon S3.

You can back up an SSAS database as follows:

- A domain user with the `admin` role for a particular database can use SSMS to back up the database to the `D:\S3` folder.

For more information, see [Adding a domain user as a database administrator \(p. 770\)](#).

- You can use the following stored procedure.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_BACKUP_DB',
@database_name='myssasdb',
@file_path='D:\S3\ssas_db_backup.abf',
[@ssas_apply_compression=1],
```

```
[@ssas_overwrite_file=1];
```

The following parameters are required:

- @task_type – The type of the MSBI task, in this case SSAS_BACKUP_DB.
- @database_name – The name of the SSAS database that you're backing up.
- @file_path – The path for the SSAS backup file. The .abf extension is required.

The following parameters are optional:

- @ssas_apply_compression – Whether to apply SSAS backup compression. Valid values are 1 (Yes) and 0 (No).
- @ssas_overwrite_file – Whether to overwrite the SSAS backup file. Valid values are 1 (Yes) and 0 (No).

Note

The stored procedure for backup doesn't support encryption.

Restoring an SSAS database

Use the following stored procedure to restore an SSAS database from a backup.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSAS_RESTORE_DB',
@database_name='mynewssasdb',
@file_path='D:\S3\ssas_db_backup.abf';
```

The following parameters are required:

- @task_type – The type of the MSBI task, in this case SSAS_RESTORE_DB.
- @database_name – The name of the new SSAS database that you're restoring to.
- @file_path – The path to the SSAS backup file.

Note

You can't restore a database if there is an existing SSAS database with the same name. The stored procedure for restoring doesn't support encrypted backup files.

Restoring a DB instance to a specified time

Point-in-time recovery (PITR) doesn't apply to SSAS databases. If you do PITR, only the SSAS data in the last snapshot before the requested time is available on the restored instance.

To have up-to-date SSAS databases on a restored DB instance

1. Back up your SSAS databases to the D:\S3 folder on the source instance.
2. Transfer the backup files to the S3 bucket.
3. Transfer the backup files from the S3 bucket to the D:\S3 folder on the restored instance.
4. Run the stored procedure to restore the SSAS databases onto the restored instance.

Note

You can also reprocess the SSAS project to restore the databases.

Disabling SSAS

To disable SSAS, remove the SSAS option from its option group. Before you remove the SSAS option, delete your SSAS databases.

Important

We highly recommend that you back up your SSAS databases before deleting them and removing the SSAS option.

Console

To remove the SSAS option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the SSAS option (ssas-se-2017 in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **SSAS** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

CLI

To remove the SSAS option from its option group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
    --option-group-name ssas-se-2017 \
    --options SSAS \
    --apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group ^
    --option-group-name ssas-se-2017 ^
    --options SSAS ^
    --apply-immediately
```

Support for SQL Server Integration Services in Amazon RDS for SQL Server

Microsoft SQL Server Integration Services (SSIS) is a component that you can use to perform a broad range of data migration tasks. SSIS is a platform for data integration and workflow applications. It features a data warehousing tool used for data extraction, transformation, and loading (ETL). You can also use this tool to automate maintenance of SQL Server databases and updates to multidimensional cube data.

SSIS projects are organized into packages saved as XML-based .dtsx files. Packages can contain control flows and data flows. You use data flows to represent ETL operations. After deployment, packages are stored in SQL Server in the SSISDB database. SSISDB is an online transaction processing (OLTP) database in the full recovery mode.

Amazon RDS for SQL Server supports running SSIS directly on an RDS DB instance. You can enable SSIS on an existing or new DB instance. SSIS is installed on the same DB instance as your database engine.

RDS supports SSIS for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2019, version 15.00.4043.16.v1 and later
- SQL Server 2017, version 14.00.3223.3.v1 and later
- SQL Server 2016, version 13.00.5426.0.v1 and later

Limitations and recommendations

The following limitations and recommendations apply to running SSIS on RDS for SQL Server:

- The DB instance must use AWS Managed Microsoft AD for SSIS authentication.
- The DB instance must have an associated parameter group with the `clr_enabled` parameter set to 1. For more information, see [Modifying the parameter for SSIS \(p. 777\)](#).

Note

If you enable the `clr_enabled` parameter on SQL Server 2017, you can't use the common language runtime (CLR) on your DB instance.

- The following control flow tasks are supported:
 - Analysis Services Execute DDL Task
 - Analysis Services Processing Task
 - Bulk Insert Task
 - Check Database Integrity Task
 - Data Flow Task
 - Data Mining Query Task
 - Data Profiling Task
 - Execute Package Task
 - Execute SQL Server Agent Job Task
 - Execute SQL Task
 - Execute T-SQL Statement Task
 - Notify Operator Task
 - Rebuild Index Task
 - Reorganize Index Task
 - Shrink Database Task
 - Transfer Database Task

- Transfer Jobs Task
- Transfer Logins Task
- Transfer SQL Server Objects Task
- Update Statistics Task
- Only project deployment is supported.
- Running SSIS packages by using SQL Server Agent is supported.
- Only SQL Server-based logging is supported.
- Use only the D:\S3 folder for working with files. Files placed in any other directory are deleted. Be aware of a few other file location details:
 - Place SSIS project input and output files in the D:\S3 folder.
 - For the Data Flow Task, change the location for BLOBTempStoragePath and BufferTempStoragePath to a file inside the D:\S3 folder.
 - Ensure that all parameters, variables, and expressions used for file connections point to the D:\S3 folder.
 - On Multi-AZ instances, files created by SSIS in the D:\S3 folder are deleted after a failover. For more information, see [Multi-AZ limitations for S3 integration \(p. 731\)](#).
 - Upload the files created by SSIS in the D:\S3 folder to your Amazon S3 bucket to make them durable.
- Import Column and Export Column transformations and the Script component on the Data Flow Task aren't supported.
- You can't enable dump on running SSIS packages, and you can't add data taps on SSIS packages.
- The SSIS Scale Out feature isn't supported.
- You can't deploy projects directly. We provide RDS stored procedures to do this. For more information, see [Deploying an SSIS project \(p. 781\)](#).
- Build SSIS project (.ispac) files with the DoNotSavePasswords protection mode for deploying on RDS.
- SSIS isn't supported on Always On instances with read replicas.
- You can't back up the SSISDB database that is associated with the SSIS option.
- Importing and restoring the SSISDB database from other instances of SSIS isn't supported.

Enabling SSIS

You enable SSIS by adding the SSIS option to your DB instance. Use the following process:

1. Create a new option group, or choose an existing option group.
2. Add the SSIS option to the option group.
3. Create a new parameter group, or choose an existing parameter group.
4. Modify the parameter group to set the clr_enabled parameter to 1.
5. Associate the option group and parameter group with the DB instance.
6. Enable Amazon S3 integration.

Note

If a database with the name SSISDB or a reserved SSIS login already exists on the DB instance, you can't enable SSIS on the instance.

Creating the option group for SSIS

To work with SSIS, create an option group or modify an option group that corresponds to the SQL Server edition and version of the DB instance that you plan to use. To do this, use the AWS Management Console or the AWS CLI.

Console

The following procedure creates an option group for SQL Server Standard Edition 2016.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** window, do the following:
 - a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **ssis-se-2016**. The name can contain only letters, digits, and hyphens.
 - b. For **Description**, enter a brief description of the option group, such as **SSIS option group for SQL Server SE 2016**. The description is used for display purposes.
 - c. For **Engine**, choose **sqlserver-se**.
 - d. For **Major engine version**, choose **13.00**.
5. Choose **Create**.

CLI

The following procedure creates an option group for SQL Server Standard Edition 2016.

To create the option group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds create-option-group \
    --option-group-name ssis-se-2016 \
    --engine-name sqlserver-se \
    --major-engine-version 13.00 \
    --option-group-description "SSIS option group for SQL Server SE 2016"
```

For Windows:

```
aws rds create-option-group ^
    --option-group-name ssis-se-2016 ^
    --engine-name sqlserver-se ^
    --major-engine-version 13.00 ^
    --option-group-description "SSIS option group for SQL Server SE 2016"
```

Adding the SSIS option to the option group

Next, use the AWS Management Console or the AWS CLI to add the **ssis** option to your option group.

Console

To add the SSIS option

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.

2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created, **ssis-se-2016** in this example.
4. Choose **Add option**.
5. Under **Option details**, choose **SSIS** for **Option name**.
6. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
7. Choose **Add option**.

CLI

To add the SSIS option

- Add the SSIS option to the option group.

Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
--option-group-name ssis-se-2016 \
--options OptionName=SSIS \
--apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
--option-group-name ssis-se-2016 ^
--options OptionName=SSIS ^
--apply-immediately
```

Creating the parameter group for SSIS

Create or modify a parameter group for the `clr` enabled parameter that corresponds to the SQL Server edition and version of the DB instance that you plan to use for SSIS.

Console

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
4. In the **Create parameter group** pane, do the following:
 - a. For **Parameter group family**, choose **sqlserver-se-13.0**.
 - b. For **Group name**, enter an identifier for the parameter group, such as **ssis-sqlserver-se-13**.
 - c. For **Description**, enter **clr enabled parameter group**.
5. Choose **Create**.

CLI

The following procedure creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
--db-parameter-group-name ssis-sqlserver-se-13 \
--db-parameter-group-family "sqlserver-se-13.0" \
--description "clr enabled parameter group"
```

For Windows:

```
aws rds create-db-parameter-group ^
--db-parameter-group-name ssis-sqlserver-se-13 ^
--db-parameter-group-family "sqlserver-se-13.0" ^
--description "clr enabled parameter group"
```

Modifying the parameter for SSIS

Modify the `clr enabled` parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance. For SSIS, set the `clr enabled` parameter to 1.

Console

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

- Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
- In the navigation pane, choose **Parameter groups**.
- Choose the parameter group, such as **ssis-sqlserver-se-13**.
- Under **Parameters**, filter the parameter list for `clr`.
- Choose `clr enabled`.
- Choose **Edit parameters**.
- From **Values**, choose **1**.
- Choose **Save changes**.

CLI

The following procedure modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name ssis-sqlserver-se-13 \
--parameters "ParameterName='clr enabled',ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name ssis-sqlserver-se-13 ^
--parameters "ParameterName='clr enabled',ParameterValue=1,ApplyMethod=immediate"
```

Associating the option group and parameter group with your DB instance

To associate the SSIS option group and parameter group with your DB instance, use the AWS Management Console or the AWS CLI

Note

If you use an existing instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see [Using Windows Authentication with an Amazon RDS for SQL Server DB instance \(p. 711\)](#).

Console

To finish enabling SSIS, associate your SSIS option group and parameter group with a new or existing DB instance:

- For a new DB instance, associate them when you launch the instance. For more information, see [Creating an Amazon RDS DB instance \(p. 141\)](#).
- For an existing DB instance, associate them by modifying the instance. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

CLI

You can associate the SSIS option group and parameter group with a new or existing DB instance.

To create an instance with the SSIS option group and parameter group

- Specify the same DB engine type and major version as you used when creating the option group.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
--db-instance-identifier myssisisinstance \
--db-instance-class db.m5.2xlarge \
--engine sqlserver-se \
--engine-version 13.00.5426.0.v1 \
--allocated-storage 100 \
--master-user-password secret123 \
--master-username admin \
--storage-type gp2 \
--license-model li \
```

```
--domain-iam-role-name my-directory-iam-role \
--domain my-domain-id \
--option-group-name ssis-se-2016 \
--db-parameter-group-name ssis-sqlserver-se-13
```

For Windows:

```
aws rds create-db-instance ^
--db-instance-identifier myssisisinstance ^
--db-instance-class db.m5.2xlarge ^
--engine sqlserver-se ^
--engine-version 13.00.5426.0.v1 ^
--allocated-storage 100 ^
--master-user-password secret123 ^
--master-username admin ^
--storage-type gp2 ^
--license-model li ^
--domain-iam-role-name my-directory-iam-role ^
--domain my-domain-id ^
--option-group-name ssis-se-2016 ^
--db-parameter-group-name ssis-sqlserver-se-13
```

To modify an instance and associate the SSIS option group and parameter group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier myssisisinstance \
--option-group-name ssis-se-2016 \
--db-parameter-group-name ssis-sqlserver-se-13 \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier myssisisinstance ^
--option-group-name ssis-se-2016 ^
--db-parameter-group-name ssis-sqlserver-se-13 ^
--apply-immediately
```

Enabling S3 integration

To download SSIS project (.ispac) files to your host for deployment, use S3 file integration. For more information, see [Integrating an Amazon RDS for SQL Server DB instance with Amazon S3 \(p. 721\)](#).

Administrative permissions on SSISDB

When the instance is created or modified with the SSIS option, the result is an SSISDB database with the ssis_admin and ssis_logreader roles granted to the master user. The master user has the following privileges in SSISDB:

- alter on ssis_admin role

- alter on ssis_logreader role
- alter any user

Because the master user is a SQL-authenticated user, you can't use the master user for executing SSIS packages. The master user can use these privileges to create new SSISDB users and add them to the ssis_admin and ssis_logreader roles. Doing this is useful for giving access to your domain users for using SSIS.

Setting up a Windows-authenticated user for SSIS

The master user can use the following code example to set up a Windows-authenticated login in SSISDB and grant the required procedure permissions. Doing this grants permissions to the domain user to deploy and run SSIS packages, use S3 file transfer procedures, create credentials, and work with the SQL Server Agent proxy. For more information, see [Credentials \(database engine\)](#) and [Create a SQL Server Agent proxy](#) in the Microsoft documentation.

Note

You can grant some or all of the following permissions as needed to Windows-authenticated users.

Example

```
USE [SSISDB]
GO
CREATE USER [mydomain\user_name] FOR LOGIN [mydomain\user_name]
ALTER ROLE [ssis_admin] ADD MEMBER [mydomain\user_name]
ALTER ROLE [ssis_logreader] ADD MEMBER [mydomain\user_name]
GO

USE [msdb]
GO
CREATE USER [mydomain\user_name] FOR LOGIN [mydomain\user_name]
GRANT EXEC ON msdb.dbo.rds_msbi_task TO [mydomain\user_name] with grant option
GRANT SELECT ON msdb.dbo.rds_fn_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_task_status TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_cancel_task TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_download_from_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_upload_to_s3 TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_delete_from_filesystem TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_gather_file_details TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_add_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_update_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_grant_login_to_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_revoke_login_from_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_delete_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_login_for_proxy TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.sp_enum_proxy_for_subsystem TO [mydomain\user_name] with grant option
GRANT EXEC ON msdb.dbo.rds_sqlagent_proxy TO [mydomain\user_name] WITH GRANT OPTION
ALTER ROLE [SQLAgentUserRole] ADD MEMBER [mydomain\user_name]
GO

USE [master]
GO
GRANT ALTER ANY CREDENTIAL TO [mydomain\user_name]
GO
```

Deploying an SSIS project

On RDS, you can't deploy SSIS projects directly by using SQL Server Management Studio (SSMS) or SSIS procedures. To download project files from Amazon S3 and then deploy them, use RDS stored procedures.

To run the stored procedures, log in as any user that you granted permissions for running the stored procedures. For more information, see [Setting up a Windows-authenticated user for SSIS \(p. 780\)](#).

To deploy the SSIS project

1. Download the project (.ispac) file.

```
exec msdb.dbo.rds_download_from_s3
@s3_arn_of_file='arn:aws:s3:::bucket_name/ssisproject.ispac',
[@rds_file_path='D:\S3\ssisproject.ispac'],
[@overwrite_file=1];
```

2. Submit the deployment task, making sure of the following:

- The folder is present in the SSIS catalog.
- The project name matches the project name that you used while developing the SSIS project.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSIS_DEPLOY_PROJECT',
@folder_name='DEMO',
@project_name='ssisproject',
@file_path='D:\S3\ssisproject.ispac';
```

Monitoring the status of a deployment task

To track the status of your deployment task, call the `rds_fn_task_status` function. It takes two parameters. The first parameter should always be `NULL` because it doesn't apply to SSIS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to `NULL` and the second parameter to 0, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,0);
```

To get a specific task, set the first parameter to `NULL` and the second parameter to the task ID, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,42);
```

The `rds_fn_task_status` function returns the following information.

Output parameter	Description
<code>task_id</code>	The ID of the task.
<code>task_type</code>	<code>SSIS_DEPLOY_PROJECT</code>

Output parameter	Description
database_name	Not applicable to SSIS tasks.
% complete	The progress of the task as a percentage.
duration (mins)	The amount of time spent on the task, in minutes.
lifecycle	<p>The status of the task. Possible statuses are the following:</p> <ul style="list-style-type: none"> • CREATED – After you call the <code>msdb.dbo.rds_msbi_task</code> stored procedure, a task is created and the status is set to CREATED. • IN_PROGRESS – After a task starts, the status is set to IN_PROGRESS. It can take up to five minutes for the status to change from CREATED to IN_PROGRESS. • SUCCESS – After a task completes, the status is set to SUCCESS. • ERROR – If a task fails, the status is set to ERROR. For more information about the error, see the <code>task_info</code> column. • CANCEL_REQUESTED – After you call <code>rds_cancel_task</code>, the status of the task is set to CANCEL_REQUESTED. • CANCELLED – After a task is successfully canceled, the status of the task is set to CANCELLED.
task_info	Additional information about the task. If an error occurs during processing, this column contains information about the error.
last_updated	The date and time that the task status was last updated.
created_at	The date and time that the task was created.
S3_object_arn	Not applicable to SSIS tasks.
overwrite_S3_backup_file	Not applicable to SSIS tasks.
KMS_master_key_arn	Not applicable to SSIS tasks.
filepath	Not applicable to SSIS tasks.
overwrite_file	Not applicable to SSIS tasks.
task_metadata	Metadata associated with the SSIS task.

Using SSIS

After deploying the SSIS project into the SSIS catalog, you can run packages directly from SSMS or schedule them by using SQL Server Agent. You must use a Windows-authenticated login for executing SSIS packages. For more information, see [Setting up a Windows-authenticated user for SSIS \(p. 780\)](#).

Setting database connection managers for SSIS projects

When you use a connection manager, you can use these types of authentication:

- For local database connections, you can use SQL authentication or Windows authentication. For Windows authentication, use `DB_instance_name.fully_qualified_domain_name` as the server name of the connection string.

An example is `myssisinstance.corp-ad.example.com`, where `myssisinstance` is the DB instance name and `corp-ad.example.com` is the fully qualified domain name.

- For remote connections, always use SQL authentication.

Creating an SSIS proxy

To be able to schedule SSIS packages using SQL Server Agent, create an SSIS credential and an SSIS proxy. Run these procedures as a Windows-authenticated user.

To create the SSIS credential

- Create the credential for the proxy. To do this, you can use SSMS or the following SQL statement.

```
USE [master]
GO
CREATE CREDENTIAL [SSIS_Credential] WITH IDENTITY = N'mydomain\user_name', SECRET =
N'mysecret'
GO
```

Note

`IDENTITY` must be a domain-authenticated login. Replace `mysecret` with the password for the domain-authenticated login.

Whenever the SSISDB primary host is changed, alter the SSIS proxy credentials to allow the new host to access them.

To create the SSIS proxy

1. Use the following SQL statement to create the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_add_proxy
    @proxy_name=N'SSIS_Proxy',@credential_name=N'SSIS_Credential',@description=N''
GO
```

2. Use the following SQL statement to grant access to the proxy to other users.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_grant_login_to_proxy
    @proxy_name=N'SSIS_Proxy',@login_name=N'mydomain\user_name'
GO
```

3. Use the following SQL statement to give the SSIS subsystem access to the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
    @task_type='GRANT_SUBSYSTEM_ACCESS',@proxy_name='SSIS_Proxy',@proxy_subsystem='SSIS'
```

GO

To view the proxy and grants on the proxy

1. Use the following SQL statement to view the grantees of the proxy.

```
USE [msdb]
GO
EXEC sp_help_proxy
GO
```

2. Use the following SQL statement to view the subsystem grants.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_enum_proxy_for_subsystem
GO
```

Scheduling an SSIS package using SQL Server Agent

After you create the credential and proxy and grant SSIS access to the proxy, you can create a SQL Server Agent job to schedule the SSIS package.

To schedule the SSIS package

- You can use SSMS or T-SQL for creating the SQL Server Agent job. The following example uses T-SQL.

```
USE [msdb]
GO
DECLARE @jobId BINARY(16)
EXEC msdb.dbo.sp_add_job @job_name=N'MYSSISJob',
@enabled=1,
@notify_level_eventlog=0,
@notify_level_email=2,
@notify_level_page=2,
@delete_level=0,
@category_name=N'[Uncategorized (Local)]',
@job_id = @jobId OUTPUT
GO
EXEC msdb.dbo.sp_add_jobserver @job_name=N'MYSSISJob',@server_name=N'(local)'
GO
EXEC msdb.dbo.sp_add_jobstep @job_name=N'MYSSISJob',@step_name=N'ExecuteSSISPackage',
@step_id=1,
@cmdexec_success_code=0,
@on_success_action=1,
@on_fail_action=2,
@retry_attempts=0,
@retry_interval=0,
@os_run_priority=0,
@subsystem=N'SSIS',
@command=N'/ISSERVER "\"\\SSISDB\\MySSISFolder\\MySSISProject\\MySSISPackage.dtsx\" /'
SERVER "\"my-rds-ssis-instance.corp-ad.company.com\/\""
/Par "\"$ServerOption::LOGGING_LEVEL(Int16)\";1 /Par
"\"$ServerOption::SYNCHRONIZED(Boolean)\"";True /CALLERINFO SQLAGENT /REPORTING E',
@database_name=N'master',
@flags=0,
@proxy_name=N'SSIS_Proxy'
GO
```

Revoking SSIS access from the proxy

You can revoke access to the SSIS subsystem and delete the SSIS proxy using the following stored procedures.

To revoke access and delete the proxy

1. Revoke subsystem access.

```
USE [msdb]
GO
EXEC msdb.dbo.rds_sqlagent_proxy
    @task_type='REVOKE_SUBSYSTEM_ACCESS',@proxy_name='SSIS_Proxy',@proxy_subsystem='SSIS'
GO
```

2. Revoke the grants on the proxy.

```
USE [msdb]
GO
EXEC msdb.dbo.sp_revoke_login_from_proxy
    @proxy_name=N'SSIS_Proxy',@name=N'mydomain\user_name'
GO
```

3. Delete the proxy.

```
USE [msdb]
GO
EXEC dbo.sp_delete_proxy @proxy_name = N'SSIS_Proxy'
GO
```

Disabling SSIS

To disable SSIS, remove the `SSIS` option from its option group.

Important

Removing the option doesn't delete the SSISDB database, so you can safely remove the option without losing the SSIS projects.

You can re-enable the `SSIS` option after removal to reuse the SSIS projects that were previously deployed to the SSIS catalog.

Console

The following procedure removes the `SSIS` option.

To remove the SSIS option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the `SSIS` option (`ssis-se-2016` in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **SSIS** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

CLI

The following procedure removes the SSIS option.

To remove the SSIS option from its option group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
    --option-group-name ssis-se-2016 \
    --options SSIS \
    --apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group ^
    --option-group-name ssis-se-2016 ^
    --options SSIS ^
    --apply-immediately
```

Dropping the SSISDB database

After removing the SSIS option, the SSISDB database isn't deleted. To drop the SSISDB database, use the `rds_drop_ssdb_database` stored procedure after removing the SSIS option.

To drop the SSIS database

- Use the following stored procedure.

```
USE [msdb]
GO
EXEC dbo.rds_drop_ssdb_database
GO
```

After dropping the SSISDB database, if you re-enable the SSIS option you get a fresh SSISDB catalog.

Support for SQL Server Reporting Services in Amazon RDS for SQL Server

Microsoft SQL Server Reporting Services (SSRS) is a server-based application used for report generation and distribution. It's part of a suite of SQL Server services that also includes SQL Server Analysis Services (SSAS) and SQL Server Integration Services (SSIS). SSRS is a service built on top of SQL Server. You can use it to collect data from various data sources and present it in a way that's easily understandable and ready for analysis.

Amazon RDS for SQL Server supports running SSRS directly on RDS DB instances. You can enable SSRS for existing or new DB instances.

RDS supports SSRS for SQL Server Standard and Enterprise Editions on the following versions:

- SQL Server 2019, version 15.00.4043.16.v1 and later
- SQL Server 2017, version 14.00.3223.3.v1 and later
- SQL Server 2016, version 13.00.5820.21.v1 and later

Limitations and recommendations

The following limitations and recommendations apply to running SSRS on RDS for SQL Server:

- Instances must use AWS Managed Microsoft AD for SSRS web portal and web server authentication.
- Importing and restoring report server databases from other instances of SSRS isn't supported.

Make sure to use the databases that are created when the `SSRS` option is added to the RDS DB instance. For more information, see [Report server databases \(p. 791\)](#).

- You can't configure SSRS to listen on the default SSL port (443). The allowed values are 1150–49511, except 1234, 1434, 3260, 3343, 3389, and 47001.
- Subscriptions through email or a Microsoft Windows file share aren't supported.
- Using Reporting Services Configuration Manager isn't supported.
- Creating and modifying roles isn't supported.
- Modifying report server properties isn't supported.
- System administrator and system user roles aren't granted.
- You can't edit system-level role assignments through the web portal.

Enabling SSRS

Use the following process to enable SSRS on your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the `SSRS` option to the option group.
3. Associate the option group with the DB instance.
4. Allow inbound access to the virtual private cloud (VPC) security group for the SSRS listener port.

Creating an option group for SSRS

To work with SSRS, create an option group that corresponds to the SQL Server engine and version of the DB instance that you plan to use. To do this, use the AWS Management Console or the AWS CLI.

Note

You can also use an existing option group if it's for the correct SQL Server engine and version.

Console

The following procedure creates an option group for SQL Server Standard Edition 2017.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** pane, do the following:
 - a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **ssrs-se-2017**. The name can contain only letters, digits, and hyphens.
 - b. For **Description**, enter a brief description of the option group, such as **SSRS option group for SQL Server SE 2017**. The description is used for display purposes.
 - c. For **Engine**, choose **sqlserver-se**.
 - d. For **Major engine version**, choose **14.00**.
5. Choose **Create**.

CLI

The following procedure creates an option group for SQL Server Standard Edition 2017.

To create the option group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds create-option-group \
--option-group-name ssrs-se-2017 \
--engine-name sqlserver-se \
--major-engine-version 14.00 \
--option-group-description "SSRS option group for SQL Server SE 2017"
```

For Windows:

```
aws rds create-option-group ^
--option-group-name ssrs-se-2017 ^
--engine-name sqlserver-se ^
--major-engine-version 14.00 ^
--option-group-description "SSRS option group for SQL Server SE 2017"
```

Adding the SSRS option to your option group

Next, use the AWS Management Console or the AWS CLI to add the SSRS option to your option group.

Console

To add the SSRS option

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created.
4. Choose **Add option**.
5. Under **Option details**, choose **SSRS** for **Option name**.
6. Under **Option settings**, do the following:
 - a. Enter the port for the SSRS service to listen on. The default is 8443. For a list of allowed values, see [Limitations and recommendations \(p. 787\)](#).
 - b. Enter a value for **Max memory**.

Max memory specifies the upper threshold above which no new memory allocation requests are granted to report server applications. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80.

7. For **Security groups**, choose the VPC security group to associate with the option. Use the same security group that is associated with your DB instance.
8. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
9. Choose **Add option**.

CLI

To add the SSRS option

1. Create a JSON file, for example `ssrs-option.json`, with the following parameters:
 - `OptionGroupName` – The name of option group that you created or chose previously (`ssrs-se-2017` in the following example).
 - `Port` – The port for the SSRS service to listen on. The default is 8443. For a list of allowed values, see [Limitations and recommendations \(p. 787\)](#).
 - `VpcSecurityGroupMemberships` – VPC security group memberships for your RDS DB instance.
 - `MAX_MEMORY` – The upper threshold above which no new memory allocation requests are granted to report server applications. The number is a percentage of the total memory of the DB instance. The allowed values are 10–80.

```
{  
  "OptionGroupName": "ssrs-se-2017",  
  "OptionsToInclude": [  
    {  
      "OptionName": "SSRS",  
      "Port": 8443,  
      "VpcSecurityGroupMemberships": ["sg-0abcdef123"],  
      "OptionSettings": [{"Name": "MAX_MEMORY", "Value": "60"}]  
    }],  
  "ApplyImmediately": true  
}
```

2. Add the SSRS option to the option group.

Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \
    --cli-input-json file://ssrs-option.json \
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^
    --cli-input-json file://ssrs-option.json ^
    --apply-immediately
```

Associating your option group with your DB instance

Use the AWS Management Console or the AWS CLI to associate your option group with your DB instance.

If you use an existing DB instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new instance, specify an existing Active Directory domain and IAM role. For more information, see [Using Windows Authentication with an Amazon RDS for SQL Server DB instance \(p. 711\)](#).

Console

You can associate your option group with a new or existing DB instance:

- For a new DB instance, associate the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance \(p. 141\)](#).
- For an existing DB instance, modify the instance and associate the new option group. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

CLI

You can associate your option group with a new or existing DB instance.

To create a DB instance that uses your option group

- Specify the same DB engine type and major version as you used when creating the option group.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier myssrsinstance \
    --db-instance-class db.m5.2xlarge \
    --engine sqlserver-se \
    --engine-version 14.00.3223.3.v1 \
    --allocated-storage 100 \
    --master-user-password secret123 \
    --master-username admin \
    --storage-type gp2 \
    --license-model li \
    --domain-iam-role-name my-directory-iam-role \
    --domain my-domain-id \
```

```
--option-group-name ssrs-se-2017
```

For Windows:

```
aws rds create-db-instance ^
--db-instance-identifier myssrsinstance ^
--db-instance-class db.m5.2xlarge ^
--engine sqlserver-se ^
--engine-version 14.00.3223.3.v1 ^
--allocated-storage 100 ^
--master-user-password secret123 ^
--master-username admin ^
--storage-type gp2 ^
--license-model li ^
--domain-iam-role-name my-directory-iam-role ^
--domain my-domain-id ^
--option-group-name ssrs-se-2017
```

To modify a DB instance to use your option group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier myssrsinstance \
--option-group-name ssrs-se-2017 \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier myssrsinstance ^
--option-group-name ssrs-se-2017 ^
--apply-immediately
```

Allowing inbound access to your VPC security group

To allow inbound access to the VPC security group associated with your DB instance, create an inbound rule for the specified SSRS listener port. For more information about setting up security groups, see [Provide access to your DB instance in your VPC by creating a security group \(p. 70\)](#).

Report server databases

When your DB instance is associated with the SSRS option, two new databases are created on your DB instance: rdsadmin_ReportServer and rdsadmin_ReportServerTempDB. These databases act as the ReportServer and ReportServerTempDB databases. SSRS stores its data in the ReportServer database and caches its data in the ReportServerTempDB database. RDS owns and manages these databases, so database operations on them such as ALTER and DROP aren't permitted.

Accessing the SSRS web portal

Use the following process to access the SSRS web portal:

1. Enable Secure Sockets Layer (SSL).
2. Grant access to domain users.
3. Access the web portal using a browser and the domain user credentials.

Enabling SSL on RDS

SSRS uses the HTTPS SSL protocol for its connections. To work with this protocol, import an SSL certificate into the Microsoft Windows operating system on your client computer.

For more information on SSL certificates, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 1634\)](#). For more information about using SSL with SQL Server, see [Using SSL with a Microsoft SQL Server DB instance \(p. 704\)](#).

Granting access to domain users

In a new SSRS activation, there are no role assignments in SSRS. To give a domain user or user group access to the web portal, RDS provides a stored procedure.

To grant access to a domain user on the web portal

- Use the following stored procedure.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSRS_GRANT_PORTAL_PERMISSION',
@ssrs_group_or_username=N'AD_domain\user';
```

The domain user or user group is granted the `RDS_SSRS_ROLE` system role. This role has the following system-level tasks granted to it:

- Execute report definitions
- Manage jobs
- Manage shared schedules
- View shared schedules

The item-level role of `Content Manager` on the root folder is also granted.

Accessing the web portal

After the `SSRS_GRANT_PORTAL_PERMISSION` task finishes successfully, you have access to the portal using a web browser. The web portal URL has the following format.

```
https://rds_endpoint:port/Reports
```

In this format, the following applies:

- `rds_endpoint` – The endpoint for the RDS DB instance that you're using with SSRS.

You can find the endpoint on the **Connectivity & security** tab for your DB instance. For more information, see [Connecting to a DB instance running the Microsoft SQL Server database engine \(p. 656\)](#).

- `port` – The listener port for SSRS that you set in the `SSRS` option.

To access the web portal

1. Enter the web portal URL in your browser.

```
https://myssrsinstance.cg034itsfake.us-east-1.rds.amazonaws.com:8443/Reports
```

2. Log in with the credentials for a domain user that you granted access with the SSRS_GRANT_PORTAL_PERMISSION task.

Deploying reports to SSRS

After you have access to the web portal, you can deploy reports to it. You can use the Upload tool in the web portal to upload reports, or deploy directly from [SQL Server data tools \(SSDT\)](#). When deploying from SSDT, ensure the following:

- The user who launched SSDT has access to the SSRS web portal.
- The TargetServerURL value in the SSRS project properties is set to the HTTPS endpoint of the RDS DB instance suffixed with ReportServer, for example:

```
https://myssrsinstance.cg034itsfake.us-east-1.rds.amazonaws.com:8443/ReportServer
```

Revoking system-level permissions

The RDS_SSRS_ROLE system role doesn't have sufficient permissions to delete system-level role assignments. To remove a user or user group from RDS_SSRS_ROLE, use the same stored procedure that you used to grant the role but use the SSRS_REVOKER_PORTAL_PERMISSION task type.

To revoke access from a domain user for the web portal

- Use the following stored procedure.

```
exec msdb.dbo.rds_msbi_task
@task_type='SSRS_REVOKER_PORTAL_PERMISSION',
@ssrs_group_or_username=N'AD_domain\user';
```

Doing this deletes the user from the RDS_SSRS_ROLE system role. It also deletes the user from the Content Manager item-level role if the user has it.

Monitoring the status of a task

To track the status of your granting or revoking task, call the rds_fn_task_status function. It takes two parameters. The first parameter should always be `NULL` because it doesn't apply to SSRS. The second parameter accepts a task ID.

To see a list of all tasks, set the first parameter to `NULL` and the second parameter to 0, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL,0);
```

To get a specific task, set the first parameter to `NULL` and the second parameter to the task ID, as shown in the following example.

```
SELECT * FROM msdb.dbo.rds_fn_task_status(NULL, 42);
```

The `rds_fn_task_status` function returns the following information.

Output parameter	Description
<code>task_id</code>	The ID of the task.
<code>task_type</code>	For SSRS, tasks can have the following task types: <ul style="list-style-type: none"> • <code>SSRS_GRANT_PORTAL_PERMISSION</code> • <code>SSRS_REVOKE_PORTAL_PERMISSION</code>
<code>database_name</code>	Not applicable to SSRS tasks.
<code>% complete</code>	The progress of the task as a percentage.
<code>duration (mins)</code>	The amount of time spent on the task, in minutes.
<code>lifecycle</code>	The status of the task. Possible statuses are the following: <ul style="list-style-type: none"> • <code>CREATED</code> – After you call one of the SSRS stored procedures, a task is created and the status is set to <code>CREATED</code>. • <code>IN_PROGRESS</code> – After a task starts, the status is set to <code>IN_PROGRESS</code>. It can take up to five minutes for the status to change from <code>CREATED</code> to <code>IN_PROGRESS</code>. • <code>SUCCESS</code> – After a task completes, the status is set to <code>SUCCESS</code>. • <code>ERROR</code> – If a task fails, the status is set to <code>ERROR</code>. For more information about the error, see the <code>task_info</code> column. • <code>CANCEL_REQUESTED</code> – After you call the <code>rds_cancel_task</code> stored procedure, the status of the task is set to <code>CANCEL_REQUESTED</code>. • <code>CANCELLED</code> – After a task is successfully canceled, the status of the task is set to <code>CANCELLED</code>.
<code>task_info</code>	Additional information about the task. If an error occurs during processing, this column contains information about the error.
<code>last_updated</code>	The date and time that the task status was last updated.
<code>created_at</code>	The date and time that the task was created.
<code>S3_object_arn</code>	Not applicable to SSRS tasks.
<code>overwrite_S3_backup_file</code>	Not applicable to SSRS tasks.
<code>KMS_master_key_arn</code>	Not applicable to SSRS tasks.
<code>filepath</code>	Not applicable to SSRS tasks.

Output parameter	Description
overwrite_file	Not applicable to SSRS tasks.
task_metadata	Metadata associated with the SSRS task.

Disabling SSRS

To disable SSRS, remove the `SSRS` option from its option group. Removing the option doesn't delete the SSRS databases. For more information, see [Deleting the SSRS databases \(p. 796\)](#).

You can re-enable SSRS by adding back the `SSRS` option. If you have also deleted the SSRS databases, re-enabling SSRS on the same DB instance creates new report server databases.

Console

To remove the SSRS option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the `SSRS` option (`ssrs-se-2017` in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **SSRS** for **Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

CLI

To remove the SSRS option from its option group

- Run one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
--option-group-name ssrs-se-2017 \
--options SSRS \
--apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group ^
--option-group-name ssrs-se-2017 ^
--options SSRS ^
--apply-immediately
```

Deleting the SSRS databases

Removing the SSRS option doesn't delete the report server databases. To delete them, use the following stored procedure.

To delete the report server databases, be sure to remove the SSRS option first.

To delete the SSRS databases

- Use the following stored procedure.

```
exec msdb.dbo.rds_drop_ssrs_databases
```

Support for Microsoft Distributed Transaction Coordinator in SQL Server

A *distributed transaction* is a database transaction in which two or more network hosts are involved. Amazon RDS for SQL Server supports distributed transactions among hosts, where a single host can be one of the following:

- RDS for SQL Server DB instance
- On-premises SQL Server host
- Amazon EC2 host with SQL Server installed
- Any other EC2 host or RDS DB instance with a database engine that supports distributed transactions

In RDS, starting with SQL Server 2012 (version 11.00.5058.0.v1 and later), all editions of SQL Server support distributed transactions. The support is provided using Microsoft Distributed Transaction Coordinator (MSDTC). For in-depth information about MSDTC, see [Distributed Transaction Coordinator](#) in the Microsoft documentation.

Limitations

The following limitations apply to using MSDTC on RDS for SQL Server:

- MSDTC isn't supported on instances using SQL Server Database Mirroring. For more information, see [Transactions - availability groups and database mirroring](#).
- The `in-doubt xact resolution` parameter must be set to 1 or 2. For more information, see [Modifying the parameter for MSDTC \(p. 801\)](#).
- MSDTC requires all host names participating in distributed transactions to be resolvable using their computer names. RDS automatically maintains this functionality for domain-joined instances. However, for standalone instances make sure to configure the DNS server manually.
- Distributed transactions that depend on client dynamic link libraries (DLLs) on RDS instances aren't supported.

Enabling MSDTC

Use the following process to enable MSDTC for your DB instance:

1. Create a new option group, or choose an existing option group.
2. Add the `MSDTC` option to the option group.
3. Create a new parameter group, or choose an existing parameter group.
4. Modify the parameter group to set the `in-doubt xact resolution` parameter to 1 or 2.
5. Associate the option group and parameter group with the DB instance.

Creating the option group for MSDTC

Use the AWS Management Console or the AWS CLI to create an option group that corresponds to the SQL Server engine and version of your DB instance.

Note

You can also use an existing option group if it's for the correct SQL Server engine and version.

Console

The following procedure creates an option group for SQL Server Standard Edition 2016.

To create the option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose **Create group**.
4. In the **Create option group** pane, do the following:
 - a. For **Name**, enter a name for the option group that is unique within your AWS account, such as **msdtc-se-2016**. The name can contain only letters, digits, and hyphens.
 - b. For **Description**, enter a brief description of the option group, such as **MSDTC option group for SQL Server SE 2016**. The description is used for display purposes.
 - c. For **Engine**, choose **sqlserver-se**.
 - d. For **Major engine version**, choose **13.00**.
5. Choose **Create**.

CLI

The following example creates an option group for SQL Server Standard Edition 2016.

To create the option group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds create-option-group \
--option-group-name msdtc-se-2016 \
--engine-name sqlserver-se \
--major-engine-version 13.00 \
--option-group-description "MSDTC option group for SQL Server SE 2016"
```

For Windows:

```
aws rds create-option-group ^
--option-group-name msdtc-se-2016 ^
--engine-name sqlserver-se ^
--major-engine-version 13.00 ^
--option-group-description "MSDTC option group for SQL Server SE 2016"
```

Adding the MSDTC option to the option group

Next, use the AWS Management Console or the AWS CLI to add the **MSDTC** option to the option group.

The following option settings are required:

- **Port** – The port that you use to access MSDTC. Allowed values are 1150–49151 except for 1234, 1434, 3260, 3343, 3389, and 47001. The default value is 5000.

Make sure that the port you want to use is enabled in your firewall rules. Also, make sure as needed that this port is enabled in the inbound and outbound rules for the security group associated with your DB instance. For more information, see [Can't connect to Amazon RDS DB instance \(p. 1746\)](#).

- **Security groups** – The VPC or DB security group memberships for your RDS DB instance.
- **Authentication type** – The authentication mode between hosts. The following authentication types are supported:
 - Mutual – The RDS instances are mutually authenticated to each other using integrated authentication. If this option is selected, all instances associated with this option group must be domain-joined.
 - None – No authentication is performed between hosts. We don't recommend using this mode in production environments.
- **Transaction log size** – The size of the MSDTC transaction log. Allowed values are 4–1024 MB. The default size is 4 MB.

The following option settings are optional:

- **Enable inbound connections** – Whether to allow inbound MSDTC connections to instances associated with this option group.
- **Enable outbound connections** – Whether to allow outbound MSDTC connections from instances associated with this option group.
- **Enable XA** – Whether to allow XA transactions. For more information on the XA protocol, see [XA specification](#).

Note

Using custom XA dynamic link libraries isn't supported.

- **Enable SNA LU** – Whether to allow the SNA LU protocol to be used for distributed transactions. For more information on SNA LU protocol support, see [Managing IBM CICS LU 6.2 transactions](#) in the Microsoft documentation.

Console

To add the MSDTC option

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group that you just created.
4. Choose **Add option**.
5. Under **Option details**, choose **MSDTC** for **Option name**.
6. Under **Option settings**:
 - a. For **Port**, enter the port number for accessing MSDTC. The default is **5000**.
 - b. For **Security groups**, choose the VPC or DB security group to associate with the option.
 - c. For **Authentication type**, choose **Mutual** or **None**.
 - d. For **Transaction log size**, enter a value from 4–1024. The default is **4**.
7. Under **Additional configuration**, do the following:
 - a. For **Connections**, as needed choose **Enable inbound connections** and **Enable outbound connections**.
 - b. For **Allowed protocols**, as needed choose **Enable XA** and **Enable SNA LU**.
8. Under **Scheduling**, choose whether to add the option immediately or at the next maintenance window.
9. Choose **Add option**.

To add this option, no reboot is required.

CLI

To add the MSDTC option

1. Create a JSON file, for example `msdtc-option.json`, with the following required parameters.

```
{  
    "OptionGroupName": "msdtc-se-2016",  
    "OptionsToInclude": [  
        {  
            "OptionName": "MSDTC",  
            "Port": 5000,  
            "VpcSecurityGroupMemberships": ["sg-0abcdef123"],  
            "OptionSettings": [{"Name": "AUTHENTICATION", "Value": "MUTUAL"},  
                {"Name": "TRANSACTION_LOG_SIZE", "Value": "4"}]  
        },  
        "ApplyImmediately": true  
    ]  
}
```

2. Add the MSDTC option to the option group.

Example

For Linux, macOS, or Unix:

```
aws rds add-option-to-option-group \  
    --cli-input-json file://msdtc-option.json \  
    --apply-immediately
```

For Windows:

```
aws rds add-option-to-option-group ^  
    --cli-input-json file://msdtc-option.json ^  
    --apply-immediately
```

No reboot is required.

Creating the parameter group for MSDTC

Create or modify a parameter group for the `in-doubt xact resolution` parameter that corresponds to the SQL Server edition and version of your DB instance.

Console

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. Choose **Create parameter group**.
4. In the **Create parameter group** pane, do the following:
 - a. For **Parameter group family**, choose `sqlserver-se-13.0`.
 - b. For **Group name**, enter an identifier for the parameter group, such as `msdtc-sqlserver-se-13`.

- c. For **Description**, enter **in-doubt xact resolution**.
5. Choose **Create**.

CLI

The following example creates a parameter group for SQL Server Standard Edition 2016.

To create the parameter group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-parameter-group \
    --db-parameter-group-name msdtc-sqlserver-se-13 \
    --db-parameter-group-family "sqlserver-se-13.0" \
    --description "in-doubt xact resolution"
```

For Windows:

```
aws rds create-db-parameter-group ^
    --db-parameter-group-name msdtc-sqlserver-se-13 ^
    --db-parameter-group-family "sqlserver-se-13.0" ^
    --description "in-doubt xact resolution"
```

Modifying the parameter for MSDTC

Modify the **in-doubt xact resolution** parameter in the parameter group that corresponds to the SQL Server edition and version of your DB instance.

For MSDTC, set the **in-doubt xact resolution** parameter to one of the following:

- 1 – **Presume commit**. Any MSDTC in-doubt transactions are presumed to have committed.
- 2 – **Presume abort**. Any MSDTC in-doubt transactions are presumed to have stopped.

For more information, see [in-doubt xact resolution server configuration option](#) in the Microsoft documentation.

Console

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Parameter groups**.
3. Choose the parameter group, such as **msdtc-sqlserver-se-13**.
4. Under **Parameters**, filter the parameter list for **xact**.
5. Choose **in-doubt xact resolution**.
6. Choose **Edit parameters**.

7. Enter **1** or **2**.
8. Choose **Save changes**.

CLI

The following example modifies the parameter group that you created for SQL Server Standard Edition 2016.

To modify the parameter group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name msdtc-sqlserver-se-13 \
--parameters "ParameterName='in-doubt xact
resolution',ParameterValue=1,ApplyMethod=immediate"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name msdtc-sqlserver-se-13 ^
--parameters "ParameterName='in-doubt xact
resolution',ParameterValue=1,ApplyMethod=immediate"
```

Associating the option group and parameter group with the DB instance

You can use the AWS Management Console or the AWS CLI to associate the MSDTC option group and parameter group with the DB instance.

Console

You can associate the MSDTC option group and parameter group with a new or existing DB instance.

- For a new DB instance, associate them when you launch the instance. For more information, see [Creating an Amazon RDS DB instance \(p. 141\)](#).
- For an existing DB instance, associate them by modifying the instance. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

Note

If you use an domain-joined existing DB instance, it must already have an Active Directory domain and AWS Identity and Access Management (IAM) role associated with it. If you create a new domain-joined instance, specify an existing Active Directory domain and IAM role. For more information, see [Using Windows Authentication with an Amazon RDS for SQL Server DB instance \(p. 711\)](#).

CLI

You can associate the MSDTC option group and parameter group with a new or existing DB instance.

Note

If you use an existing domain-joined DB instance, it must already have an Active Directory domain and IAM role associated with it. If you create a new domain-joined instance, specify

an existing Active Directory domain and IAM role. For more information, see [Using Windows Authentication with an Amazon RDS for SQL Server DB instance \(p. 711\)](#).

To create a DB instance with the MSDTC option group and parameter group

- Specify the same DB engine type and major version as you used when creating the option group.

Example

For Linux, macOS, or Unix:

```
aws rds create-db-instance \
    --db-instance-identifier mydbinstance \
    --db-instance-class db.m5.2xlarge \
    --engine sqlserver-se \
    --engine-version 13.00.5426.0.v1 \
    --allocated-storage 100 \
    --master-user-password secret123 \
    --master-username admin \
    --storage-type gp2 \
    --license-model li \
    --domain-iam-role-name my-directory-iam-role \
    --domain my-domain-id \
    --option-group-name msdtc-se-2016 \
    --db-parameter-group-name msdtc-sqlserver-se-13
```

For Windows:

```
aws rds create-db-instance ^
    --db-instance-identifier mydbinstance ^
    --db-instance-class db.m5.2xlarge ^
    --engine sqlserver-se ^
    --engine-version 13.00.5426.0.v1 ^
    --allocated-storage 100 ^
    --master-user-password secret123 ^
    --master-username admin ^
    --storage-type gp2 ^
    --license-model li ^
    --domain-iam-role-name my-directory-iam-role ^
    --domain my-domain-id ^
    --option-group-name msdtc-se-2016 ^
    --db-parameter-group-name msdtc-sqlserver-se-13
```

To modify a DB instance and associate the MSDTC option group and parameter group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
    --db-instance-identifier mydbinstance \
    --option-group-name msdtc-se-2016 \
    --db-parameter-group-name msdtc-sqlserver-se-13 \
    --apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--option-group-name msdtc-se-2016 ^
--db-parameter-group-name msdtc-sqlserver-se-13 ^
--apply-immediately
```

Using distributed transactions

In Amazon RDS for SQL Server, you run distributed transactions in the same way as distributed transactions running on-premises:

- Using .NET framework `System.Transactions` promotable transactions, which optimizes distributed transactions by deferring their creation until they're needed.

In this case, promotion is automatic and doesn't require you to make any intervention. If there's only one resource manager within the transaction, no promotion is performed. For more information about implicit transaction scopes, see [Implementing an implicit transaction using transaction scope](#) in the Microsoft documentation.

Promotable transactions are supported with these .NET implementations:

- Starting with ADO.NET 2.0, `System.Data.SqlClient` supports promotable transactions with SQL Server. For more information, see [System.Transactions integration with SQL Server](#) in the Microsoft documentation.
- ODP.NET supports `System.Transactions`. A local transaction is created for the first connection opened in the `TransactionsScope` scope to Oracle Database 11g release 1 (version 11.1) and later. When a second connection is opened, this transaction is automatically promoted to a distributed transaction. For more information about distributed transaction support in ODP.NET, see [Microsoft Distributed Transaction Coordinator integration](#) in the Microsoft documentation.
- Using the `BEGIN DISTRIBUTED TRANSACTION` statement. For more information, see [BEGIN DISTRIBUTED TRANSACTION \(Transact-SQL\)](#) in the Microsoft documentation.

Using transaction tracing

RDS supports controlling MSDTC transaction traces and downloading them from the RDS DB instance for troubleshooting. You can control transaction tracing sessions by running the following RDS stored procedure.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'trace_action',  
[@traceall='0/1'],  
[@traceaborted='0/1'],  
[@tracelong='0/1'];
```

The following parameter is required:

- `trace_action` – The tracing action. It can be `START`, `STOP`, or `STATUS`.

The following parameters are optional:

- `@traceall` – Set to 1 to trace all distributed transactions. The default is 0.
- `@traceaborted` – Set to 1 to trace canceled distributed transactions. The default is 0.
- `@tracelong` – Set to 1 to trace long-running distributed transactions. The default is 0.

Example of START tracing action

To start a new transaction tracing session, run the following example statement.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'START',
@traceall='0',
@traceaborted='1',
@tracelong='1';
```

Note

Only one transaction tracing session can be active at one time. If a new tracing session START command is issued while a tracing session is active, an error is returned and the active tracing session remains unchanged.

Example of STOP tracing action

To stop a transaction tracing session, run the following statement.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'STOP'
```

This statement stops the active transaction tracing session and saves the transaction trace data into the log directory on the RDS DB instance. The first row of the output contains the overall result, and the following lines indicate details of the operation.

The following is an example of a successful tracing session stop.

```
OK: Trace session has been successfully stopped.
Setting log file to: D:\rdsdbdata\MSDTC\Trace\dtctrace.log
Examining D:\rdsdbdata\MSDTC\Trace\msdtctr.mof for message formats, 8 found.
Searching for TMF files on path: (null)
LogFile D:\rdsdbdata\MSDTC\Trace\dtctrace.log:
OS version      10.0.14393 (Currently running on 6.2.9200)
Start Time       <timestamp>
End Time         <timestamp>
Timezone is     @tzres.dll,-932 (Bias is 0mins)
BufferSize       16384 B
Maximum File Size    10 MB
Buffers Written   Not set (Logger may not have been stopped).
Logger Mode Settings (11000002) ( circular paged
ProcessorCount     1
Processing completed Buffers: 1, Events: 3, EventsLost: 0 :: Format Errors: 0, Unknowns:
3
Event traces dumped to d:\rdsdbdata\Log\msdtc_<timestamp>.log
```

You can use the detailed information to query the name of the generated log file. For more information about downloading log files from the RDS DB instance, see [Accessing Amazon RDS database log files \(p. 504\)](#).

The trace session logs remain on the instance for 35 days. Any older trace session logs are automatically deleted.

Example of STATUS tracing action

To trace the status of a transaction tracing session, run the following statement.

```
exec msdb.dbo.rds_msdtc_transaction_tracing 'STATUS'
```

This statement outputs the following as separate rows of the result set.

```
OK
SessionStatus: <Started/Stopped>
TraceAll: <True/False>
TraceAborted: <True/False>
TraceLongLived: <True/False>
```

The first line indicates the overall result of the operation: OK or ERROR with details, if applicable. The subsequent lines indicate details about the tracing session status:

- SessionStatus can be one of the following:
 - Started if a tracing session is running.
 - Stopped if no tracing session is running.
- The tracing session flags can be True or False depending on how they were set in the START command.

Modifying the MSDTC option

After you enable the MSDTC option, you can modify its settings. For information about how to modify option settings, see [Modifying an option setting \(p. 221\)](#).

Note

Some changes to MSDTC option settings require the MSDTC service to be restarted. This requirement can affect running distributed transactions.

Disabling MSDTC

To disable MSDTC, remove the MSDTC option from its option group.

Console

To remove the MSDTC option from its option group

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Option groups**.
3. Choose the option group with the MSDTC option (msdtc-se-2016 in the previous examples).
4. Choose **Delete option**.
5. Under **Deletion options**, choose **MSDTC for Options to delete**.
6. Under **Apply immediately**, choose **Yes** to delete the option immediately, or **No** to delete it at the next maintenance window.
7. Choose **Delete**.

CLI

To remove the MSDTC option from its option group

- Use one of the following commands.

Example

For Linux, macOS, or Unix:

```
aws rds remove-option-from-option-group \
--option-group-name msdtc-se-2016 \
```

```
--options MSDTC \
--apply-immediately
```

For Windows:

```
aws rds remove-option-from-option-group ^
--option-group-name msdtc-se-2016 ^
--options MSDTC ^
--apply-immediately
```

Troubleshooting MSDTC for RDS for SQL Server

In some cases, you might have trouble establishing a connection between MSDTC running on a client computer and the MSDTC service running on an RDS for SQL Server DB instance. If so, make sure of the following:

- The inbound rules for the security group associated with the DB instance are configured correctly. For more information, see [Can't connect to Amazon RDS DB instance \(p. 1746\)](#).
- Your client computer is configured correctly.
- The MSDTC firewall rules on your client computer are enabled.

To configure the client computer

1. Open **Component Services**.
Or, in **Server Manager**, choose **Tools**, and then choose **Component Services**.
2. Expand **Component Services**, expand **Computers**, expand **My Computer**, and then expand **Distributed Transaction Coordinator**.
3. Open the context (right-click) menu for **Local DTC** and choose **Properties**.
4. Choose the **Security** tab.
5. Choose all of the following:
 - **Network DTC Access**
 - **Allow Inbound**
 - **Allow Outbound**
6. Make sure that the correct authentication mode is chosen:
 - **Mutual Authentication Required** – The client machine is joined to the same domain as other nodes participating in distributed transaction, or there is a trust relationship configured between domains.
 - **No Authentication Required** – All other cases.
7. Choose **OK** to save your changes.
8. If prompted to restart the service, choose **Yes**.

To enable MSDTC firewall rules

1. Open Windows Firewall, then choose **Advanced settings**.

Or, in **Server Manager**, choose **Tools**, and then choose **Windows Firewall with Advanced Security**.

Note

Depending on your operating system, Windows Firewall might be called Windows Defender Firewall.

2. Choose **Inbound Rules** in the left pane.
3. Enable the following firewall rules, if they are not already enabled:
 - **Distributed Transaction Coordinator (RPC)**
 - **Distributed Transaction Coordinator (RPC)-EPMAP**
 - **Distributed Transaction Coordinator (TCP-In)**
4. Close Windows Firewall.

Common DBA tasks for Microsoft SQL Server

This section describes the Amazon RDS-specific implementations of some common DBA tasks for DB instances that are running the Microsoft SQL Server database engine. In order to deliver a managed service experience, Amazon RDS does not provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges.

Note

When working with a SQL Server DB instance, you can run scripts to modify a newly created database, but you cannot modify the [model] database, the database used as the model for new databases.

Accessing the tempdb database on Microsoft SQL Server DB instances on Amazon RDS

You can access the tempdb database on your Microsoft SQL Server DB instances on Amazon RDS. You can run code on tempdb by using Transact-SQL through Microsoft SQL Server Management Studio (SSMS), or any other standard SQL client application. For more information about connecting to your DB instance, see [Connecting to a DB instance running the Microsoft SQL Server database engine \(p. 656\)](#).

The master user for your DB instance is granted CONTROL access to tempdb so that this user can modify the tempdb database options. The master user isn't the database owner of the tempdb database. If necessary, the master user can grant CONTROL access to other users so that they can also modify the tempdb database options.

Note

You can't run Database Console Commands (DBCC) on the tempdb database.

Modifying tempdb database options

You can modify the database options on the tempdb database on your Amazon RDS DB instances. For more information about which options can be modified, see [tempdb database](#) in the Microsoft documentation.

Database options such as the maximum file size options are persistent after you restart your DB instance. You can modify the database options to optimize performance when importing data, and to prevent running out of storage.

Optimizing performance when importing data

To optimize performance when importing large amounts of data into your DB instance, set the SIZE and FILEGROWTH properties of the tempdb database to large numbers. For more information about how to optimize tempdb, see [Optimizing tempdb performance](#) in the Microsoft documentation.

The following example demonstrates setting the size to 100 GB and file growth to 10 percent.

```
alter database[tempdb] modify file (NAME = N'templog', SIZE=100GB, FILEGROWTH = 10%)
```

Preventing storage problems

To prevent the tempdb database from using all available disk space, set the MAXSIZE property. The following example demonstrates setting the property to 2048 MB.

```
alter database [tempdb] modify file (NAME = N'templog', MAXSIZE = 2048MB)
```

Shrinking the tempdb database

There are two ways to shrink the tempdb database on your Amazon RDS DB instance. You can use the `rds_shrink_tempdbfile` procedure, or you can set the SIZE property,

Using the `rds_shrink_tempdbfile` procedure

You can use the Amazon RDS procedure `msdb.dbo.rds_shrink_tempdbfile` to shrink the tempdb database. You can only call `rds_shrink_tempdbfile` if you have CONTROL access to tempdb. When you call `rds_shrink_tempdbfile`, there is no downtime for your DB instance.

The `rds_shrink_tempdbfile` procedure has the following parameters.

Parameter name	Data type	Default	Required	Description
<code>@temp_filename</code>	SYSNAME	—	required	The logical name of the file to shrink.
<code>@target_size</code>	int	null	optional	The new size for the file, in megabytes.

The following example gets the names of the files for the `tempdb` database.

```
use tempdb;
GO

select name, * from sys.sysfiles;
GO
```

The following example shrinks a `tempdb` database file named `test_file`, and requests a new size of 10 megabytes:

```
exec msdb.dbo.rds_shrink_tempdbfile @temp_filename = N'test_file', @target_size = 10;
```

Setting the SIZE property

You can also shrink the `tempdb` database by setting the `SIZE` property and then restarting your DB instance. For more information about restarting your DB instance, see [Rebooting a DB instance \(p. 276\)](#).

The following example demonstrates setting the `SIZE` property to 1024 MB.

```
alter database [tempdb] modify file (NAME = N'templog', SIZE = 1024MB)
```

Considerations for Multi-AZ deployments

If your Amazon RDS DB instance is in a Multi-AZ Deployment for Microsoft SQL Server with Database Mirroring (DBM) or Always On Availability Groups (AGs), there are some things to consider.

The `tempdb` database can't be replicated. No data that you store on your primary instance is replicated to your secondary instance.

If you modify any database options on the `tempdb` database, you can capture those changes on the secondary by using one of the following methods:

- First modify your DB instance and turn Multi-AZ off, then modify `tempdb`, and finally turn Multi-AZ back on. This method doesn't involve any downtime.

For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

- First modify `tempdb` in the original primary instance, then fail over manually, and finally modify `tempdb` in the new primary instance. This method involves downtime.

For more information, see [Rebooting a DB instance \(p. 276\)](#).

Analyzing your database workload on an Amazon RDS DB instance with SQL Server Tuning Advisor

The Database Engine Tuning Advisor is a client application provided by Microsoft that analyzes database workload and recommends an optimal set of indexes for your Microsoft SQL Server databases based on the kinds of queries you run. Like SQL Server Management Studio, you run Tuning Advisor from a client computer that connects to your Amazon RDS DB instance that is running SQL Server. The client computer can be a local computer that you run on premises within your own network or it can be an Amazon EC2 Windows instance that is running in the same region as your Amazon RDS DB instance.

This section shows how to capture a workload for Tuning Advisor to analyze. This is the preferred process for capturing a workload because Amazon RDS restricts host access to the SQL Server instance. The full documentation on Tuning Advisor can be found on [MSDN](#).

To use Tuning Advisor, you must provide what is called a workload to the advisor. A workload is a set of Transact-SQL statements that run against a database or databases that you want to tune. Database Engine Tuning Advisor uses trace files, trace tables, Transact-SQL scripts, or XML files as workload input when tuning databases. When working with Amazon RDS, a workload can be a file on a client computer or a database table on an Amazon RDS for SQL Server DB accessible to your client computer. The file or the table must contain queries against the databases you want to tune in a format suitable for replay.

For Tuning Advisor to be most effective, a workload should be as realistic as possible. You can generate a workload file or table by performing a trace against your DB instance. While a trace is running, you can either simulate a load on your DB instance or run your applications with a normal load.

There are two types of traces: client-side and server-side. A client-side trace is easier to set up and you can watch trace events being captured in real-time in SQL Server Profiler. A server-side trace is more complex to set up and requires some Transact-SQL scripting. In addition, because the trace is written to a file on the Amazon RDS DB instance, storage space is consumed by the trace. It is important to track of how much storage space a running server-side trace uses because the DB instance could enter a storage-full state and would no longer be available if it runs out of storage space.

For a client-side trace, when a sufficient amount of trace data has been captured in the SQL Server Profiler, you can then generate the workload file by saving the trace to either a file on your local computer or in a database table on a DB instance that is available to your client computer. The main disadvantage of using a client-side trace is that the trace may not capture all queries when under heavy loads. This could weaken the effectiveness of the analysis performed by the Database Engine Tuning Advisor. If you need to run a trace under heavy loads and you want to ensure that it captures every query during a trace session, you should use a server-side trace.

For a server-side trace, you must get the trace files on the DB instance into a suitable workload file or you can save the trace to a table on the DB instance after the trace completes. You can use the SQL Server Profiler to save the trace to a file on your local computer or have the Tuning Advisor read from the trace table on the DB instance.

Running a client-side trace on a SQL Server DB instance

To run a client-side trace on a SQL Server DB instance

1. Start SQL Server Profiler. It is installed in the Performance Tools folder of your SQL Server instance folder. You must load or define a trace definition template to start a client-side trace.
2. In the SQL Server Profiler File menu, choose **New Trace**. In the **Connect to Server** dialog box, enter the DB instance endpoint, port, master user name, and password of the database you would like to run a trace on.
3. In the **Trace Properties** dialog box, enter a trace name and choose a trace definition template. A default template, `TSQL_Replay`, ships with the application. You can edit this template to define your

trace. Edit events and event information under the **Events Selection** tab of the **Trace Properties** dialog box. For more information about trace definition templates and using the SQL Server Profiler to specify a client-side trace see the documentation in [MSDN](#).

4. Start the client-side trace and watch SQL queries in real-time as they run against your DB instance.
5. Select **Stop Trace** from the **File** menu when you have completed the trace. Save the results as a file or as a trace table on your DB instance.

Running a server-side trace on a SQL Server DB instance

Writing scripts to create a server-side trace can be complex and is beyond the scope of this document. This section contains sample scripts that you can use as examples. As with a client-side trace, the goal is to create a workload file or trace table that you can open using the Database Engine Tuning Advisor.

The following is an abridged example script that starts a server-side trace and captures details to a workload file. The trace initially saves to the file RDSTrace.trc in the D:\RDSDDBDATA\Log directory and rolls-over every 100 MB so subsequent trace files are named RDSTrace_1.trc, RDSTrace_2.trc, etc.

```
DECLARE @file_name NVARCHAR(245) = 'D:\RDSDDBDATA\Log\RDSTrace';
DECLARE @max_file_size BIGINT = 100;
DECLARE @on BIT = 1
DECLARE @rc INT
DECLARE @traceid INT

EXEC @rc = sp_trace_create @traceid OUTPUT, 2, @file_name, @max_file_size
IF (@rc = 0) BEGIN
    EXEC sp_trace_setevent @traceid, 10, 1, @on
    EXEC sp_trace_setevent @traceid, 10, 2, @on
    EXEC sp_trace_setevent @traceid, 10, 3, @on
    .
    .
    EXEC sp_trace_setfilter @traceid, 10, 0, 7, N'SQL Profiler'
    EXEC sp_trace_setstatus @traceid, 1
END
```

The following example is a script that stops a trace. Note that a trace created by the previous script continues to run until you explicitly stop the trace or the process runs out of disk space.

```
DECLARE @traceid INT
SELECT @traceid = traceid FROM ::fn_trace_getinfo(default)
WHERE property = 5 AND value = 1 AND traceid <> 1

IF @traceid IS NOT NULL BEGIN
    EXEC sp_trace_setstatus @traceid, 0
    EXEC sp_trace_setstatus @traceid, 2
END
```

You can save server-side trace results to a database table and use the database table as the workload for the Tuning Advisor by using the fn_trace_gettable function. The following commands load the results of all files named RDSTrace.trc in the D:\rdsdbdata\Log directory, including all rollover files like RDSTrace_1.trc, into a table named RDSTrace in the current database.

```
SELECT * INTO RDSTrace
FROM fn_trace_gettable('D:\rdsdbdata\Log\RDSTrace.trc', default);
```

To save a specific rollover file to a table, for example the RDSTrace_1.trc file, specify the name of the rollover file and substitute 1 instead of default as the last parameter to fn_trace_gettable.

```
SELECT * INTO RDSTrace_1
```

```
FROM fn_trace_gettable('D:\rdsdbdata\Log\RDSTrace_1.trc', 1);
```

Running Tuning Advisor with a trace

Once you create a trace, either as a local file or as a database table, you can then run Tuning Advisor against your DB instance. Microsoft includes documentation on using the Database Engine Tuning Advisor in [MSDN](#). Using Tuning Advisor with Amazon RDS is the same process as when working with a standalone, remote SQL Server instance. You can either use the Tuning Advisor UI on your client machine or use the dta.exe utility from the command line. In both cases, you must connect to the Amazon RDS DB instance using the endpoint for the DB instance and provide your master user name and master user password when using Tuning Advisor.

The following code example demonstrates using the dta.exe command line utility against an Amazon RDS DB instance with an endpoint of `dta.cnazcmklsdei.us-east-1.rds.amazonaws.com`. The example includes the master user name `admin` and the master user password `test`, the example database to tune is named `RDSDTA` and the input workload is a trace file on the local machine named `C:\RDSTrace.trc`. The example command line code also specifies a trace session named `RDSTrace1` and specifies output files to the local machine named `RDSTrace.sql` for the SQL output script, `RDSTrace.txt` for a result file, and `RDSTrace.xml` for an XML file of the analysis. There is also an error table specified on the RDSDTA database named `RDSTraceErrors`.

```
dta -S dta.cnazcmklsdei.us-east-1.rds.amazonaws.com -U admin -P test -D RDSDTA -if C:\RDSTrace.trc -s RDSTrace1 -of C:\ RDSTrace.sql -or C:\ RDSTrace.txt -ox C:\ RDSTrace.xml -e RDSDTA.dbo.RDSTraceErrors
```

Here is the same example command line code except the input workload is a table on the remote Amazon RDS instance named `RDSTrace` which is on the `RDSDTA` database.

```
dta -S dta.cnazcmklsdei.us-east-1.rds.amazonaws.com -U admin -P test -D RDSDTA -it RDSDTA.dbo.RDSTrace -s RDSTrace1 -of C:\ RDSTrace.sql -or C:\ RDSTrace.txt -ox C:\ RDSTrace.xml -e RDSDTA.dbo.RDSTraceErrors
```

A full list of dta utility command-line parameters can be found in [MSDN](#).

Collations and character sets for Microsoft SQL Server

SQL Server supports collations at multiple levels. You set the default server collation when you create the DB instance. You can override the collation in the database, table, or column level.

Topics

- [Server-level collation for Microsoft SQL Server \(p. 814\)](#)
- [Database-level collation for Microsoft SQL Server \(p. 816\)](#)

Server-level collation for Microsoft SQL Server

When you create a Microsoft SQL Server DB instance, you can set the server collation that you want to use. If you don't choose a different collation, the server-level collation defaults to `SQL_Latin1_General_CI_AS`. The server collation is applied by default to all databases and database objects.

Note

You can't change the collation when you restore from a DB snapshot.

Currently, Amazon RDS supports the following server collations:

Collation	Description
Chinese_PRC_CI_AS	Chinese-PRC, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Chinese_Taiwan_Stroke_CI_AS	Chinese-Taiwan-Stroke, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Finnish_Swedish_CI_AS	Finnish, Swedish, and Swedish (Finland), case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
French_CI_AS	French, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Hebrew_BIN	Hebrew, binary sort
Japanese_CI_AS	Japanese, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Korean_Wansung_CI_AS	Korean-Wansung, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Latin1_General_100_BIN	Latin1-General-100, binary sort
Latin1_General_100_BIN2	Latin1-General-100, binary code point comparison sort
Latin1_General_100_CI_AS	Latin1-General-100, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Latin1_General_BIN	Latin1-General, binary sort
Latin1_General_CI_AI	Latin1-General, case-insensitive, accent-insensitive, kanatype-insensitive, width-insensitive
Latin1_General_CI_AS	Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Latin1_General_CS_AS	Latin1-General, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive
Modern_Spanish_CI_AS	Modern-Spanish, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive
SQL_Latin1_General_CP1_CI_AI	Latin1-General, case-insensitive, accent-insensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 54 on Code Page 1252 for non-Unicode Data
SQL_Latin1_General_CP1_CI_AS (default)	Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 52 on Code Page 1252 for non-Unicode Data
SQL_Latin1_General_CP1_CS_AS	Latin1-General, case-sensitive, accent-sensitive, kanatype-insensitive, width-insensitive for

Collation	Description
	Unicode Data, SQL Server Sort Order 51 on Code Page 1252 for non-Unicode Data
SQL_Latin1_General_CI_AS	Latin1-General, case-insensitive, accent-insensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 34 on Code Page 437 for non-Unicode Data
SQL_Latin1_General_CI_AS_BIN	Latin1-General, binary code point comparison sort for Unicode Data, SQL Server Sort Order 40 on Code Page 850 for non-Unicode Data
SQL_Latin1_General_CI_AS_WS	Latin1-General, case-insensitive, accent-sensitive, kanatype-insensitive, width-insensitive for Unicode Data, SQL Server Sort Order 42 on Code Page 850 for non-Unicode Data

To choose the collation:

- If you're using the Amazon RDS console, when creating a new DB instance choose **Additional configuration**, then choose the collation from the **Collation** menu under **Database options**. For more information, see [Creating an Amazon RDS DB instance \(p. 141\)](#).
- If you're using the AWS CLI, use the `--character-set-name` option with the `create-db-instance` command. For more information, see [create-db-instance](#).
- If you're using the Amazon RDS API, use the `CharacterSetName` parameter with the `CreateDBInstance` operation. For more information, see [CreateDBInstance](#).

Database-level collation for Microsoft SQL Server

You can change the default collation at the database, table, or column level by overriding the collation when creating a new database or database object. For example, if your default server collation is `SQL_Latin1_General_CI_AS`, you can change it to `Mohawk_100_CI_AS` for Mohawk collation support. Even arguments in a query can be type-cast to use a different collation if necessary.

For example, the following query would change the default collation for the `AccountName` column to `Mohawk_100_CI_AS`

```
CREATE TABLE [dbo].[Account]
(
    [AccountID] [nvarchar](10) NOT NULL,
    [AccountName] [nvarchar](100) COLLATE Mohawk_100_CI_AS NOT NULL
) ON [PRIMARY];
```

The Microsoft SQL Server DB engine supports Unicode by the built-in `NCHAR`, `NVARCHAR`, and `NTEXT` data types. For example, if you need CJK support, use these Unicode data types for character storage and override the default server collation when creating your databases and tables. Here are several links from Microsoft covering collation and Unicode support for SQL Server:

- [Working with collations](#)
- [Collation and international terminology](#)
- [Using SQL Server collations](#)
- [International considerations for databases and database engine applications](#)

Determining a recovery model for your Microsoft SQL Server database

In Amazon RDS, the recovery model, retention period, and database status are linked.

It's important to understand the consequences before making a change to one of these settings. Each setting can affect the others. For example:

- If you change a database's recovery model to SIMPLE or BULK_LOGGED while backup retention is enabled, Amazon RDS resets the recovery model to FULL within five minutes. This also results in RDS taking a snapshot of the DB instance.
- If you set backup retention to 0 days, RDS sets the recovery mode to SIMPLE.
- If you change a database's recovery model from SIMPLE to any other option while backup retention is set to 0 days, RDS resets the recovery model to SIMPLE.

Important

Never change the recovery model on Multi-AZ instances, even if it seems you can do so—for example, by using ALTER DATABASE. Backup retention, and therefore FULL recovery mode, is required for Multi-AZ. If you alter the recovery model, RDS immediately changes it back to FULL. This automatic reset forces RDS to completely rebuild the mirror. During this rebuild, the availability of the database is degraded for about 30-90 minutes until the mirror is ready for failover. The DB instance also experiences performance degradation in the same way it does during a conversion from Single-AZ to Multi-AZ. How long performance is degraded depends on the database storage size—the bigger the stored database, the longer the degradation.

For more information on SQL Server recovery models, see [Recovery models \(SQL Server\)](#) in the Microsoft documentation.

Determining the last failover time

To determine the last failover time, use the following stored procedure:

```
execute msdb.dbo.rds_failover_time;
```

This procedure returns the following information.

Output parameter	Description
errorlog_available_from	Shows the time from when error logs are available in the log directory.
recent_failover_time	Shows the last failover time if it's available from the error logs. Otherwise it shows null.

Note

The stored procedure searches all of the available SQL Server error logs in the log directory to retrieve the most recent failover time. If the failover messages have been overwritten by SQL Server, then the procedure doesn't retrieve the failover time.

Example of no recent failover

This example shows the output when there is no recent failover in the error logs. No failover has happened since 2020-04-29 23:59:00.01.

errorlog_available_from	recent_failover_time
2020-04-29 23:59:00.0100000	null

Example of recent failover

This example shows the output when there is a failover in the error logs. The most recent failover was at 2020-05-05 18:57:51.89.

errorlog_available_from	recent_failover_time
2020-04-29 23:59:00.0100000	2020-05-05 18:57:51.8900000

Disabling fast inserts during bulk loading

Starting with SQL Server 2016, fast inserts are enabled by default. Fast inserts leverage the minimal logging that occurs while the database is in the simple or bulk logged recovery model to optimize insert performance. With fast inserts, each bulk load batch acquires new extents, bypassing the allocation lookup for existing extents with available free space to optimize insert performance.

However, with fast inserts bulk loads with small batch sizes can lead to increased unused space consumed by objects. If increasing batch size isn't feasible, enabling trace flag 692 can help reduce unused reserved space, but at the expense of performance. Enabling this trace flag disables fast inserts while bulk loading data into heap or clustered indexes.

You enable trace flag 692 as a startup parameter using DB parameter groups. For more information, see [Working with DB parameter groups \(p. 228\)](#).

Trace flag 692 is supported for Amazon RDS on SQL Server 2016 and later. For more information on trace flags, see [DBCC TRACEON - trace flags](#) in the Microsoft documentation.

Dropping a Microsoft SQL Server database

You can drop a database on an Amazon RDS DB instance running Microsoft SQL Server in a Single-AZ or Multi-AZ deployment. To drop the database, use the following command:

```
--replace your-database-name with the name of the database you want to drop
EXECUTE msdb.dbo.rds_drop_database N'your-database-name'
```

Note

Use straight single quotes in the command. Smart quotes will cause an error.

After you use this procedure to drop the database, Amazon RDS drops all existing connections to the database and removes the database's backup history.

Renaming a Microsoft SQL Server database in a Multi-AZ deployment

To rename a Microsoft SQL Server database instance that uses Multi-AZ, use the following procedure:

1. First, turn off Multi-AZ for the DB instance.
2. Rename the database by running `rdsadmin.dbo.rds_modify_db_name`.

3. Then, turn on Multi-AZ Mirroring or Always On Availability Groups for the DB instance, to return it to its original state.

For more information, see [Adding Multi-AZ to a Microsoft SQL Server DB instance \(p. 699\)](#).

Note

If your instance doesn't use Multi-AZ, you don't need to change any settings before or after running `rdsadmin.dbo.rds_modify_db_name`.

Example: In the following example, the `rdsadmin.dbo.rds_modify_db_name` stored procedure renames a database from `MOO` to `ZAR`. This is similar to running the statement `DDL ALTER DATABASE [MOO] MODIFY NAME = [ZAR]`.

```
EXEC rdsadmin.dbo.rds_modify_db_name N'MOO', N'ZAR'  
GO
```

Resetting the db_owner role password

If you lock yourself out of the `db_owner` role on your Microsoft SQL Server database, you can reset the `db_owner` role password by modifying the DB instance master password. By changing the DB instance master password, you can regain access to the DB instance, access databases using the modified password for the `db_owner`, and restore privileges for the `db_owner` role that may have been accidentally revoked. You can change the DB instance password by using the Amazon RDS console, the AWS CLI command [modify-db-instance](#), or by using the [ModifyDBInstance](#) operation. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

Restoring license-terminated DB instances

Microsoft has requested that some Amazon RDS customers who did not report their Microsoft License Mobility information terminate their DB instance. Amazon RDS takes snapshots of these DB instances, and you can restore from the snapshot to a new DB instance that has the License Included model.

You can restore from a snapshot of Standard Edition to either Standard Edition or Enterprise Edition.

You can restore from a snapshot of Enterprise Edition to either Standard Edition or Enterprise Edition.

To restore from a SQL Server snapshot after Amazon RDS has created a final snapshot of your instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. Choose the snapshot of your SQL Server DB instance. Amazon RDS creates a final snapshot of your DB instance. The name of the terminated instance snapshot is in the format `instance_name-final-snapshot`. For example, if your DB instance name is `mytest.cdxgahs1ksma.us-east-1.rds.com`, the final snapshot is called `mytest-final-snapshot` and is located in the same AWS Region as the original DB instance.
4. For **Actions**, choose **Restore Snapshot**.
The **Restore DB Instance** window appears.
5. For **License Model**, choose **license-included**.
6. Choose the SQL Server DB engine that you want to use.
7. For **DB Instance Identifier**, enter the name for the restored DB instance.
8. Choose **Restore DB Instance**.

For more information about restoring from a snapshot, see [Restoring from a DB snapshot \(p. 349\)](#).

Transitioning a Microsoft SQL Server database from OFFLINE to ONLINE

You can transition your Microsoft SQL Server database on an Amazon RDS DB instance from OFFLINE to ONLINE.

SQL Server method	Amazon RDS method
ALTER DATABASE <code>db_name</code> SET ONLINE;	EXEC rdsadmin.dbo.rds_set_database_online <code>db_name</code>

Using change data capture

Amazon RDS supports change data capture (CDC) for your DB instances running Microsoft SQL Server. CDC captures changes that are made to the data in your tables. It stores metadata about each change, which you can access later. For more information about how CDC works, see [Change data capture](#) in the Microsoft documentation.

Before you use CDC with your Amazon RDS DB instances, enable it in the database by running `msdb.dbo.rds_cdc_enable_db`. You must have master user privileges to enable CDC in the Amazon RDS DB instance. After CDC is enabled, any user who is `db_owner` of that database can enable or disable CDC on tables in that database.

Important

During restores, CDC will be disabled. All of the related metadata is automatically removed from the database. This applies to snapshot restores, point-in-time restores, and SQL Server Native restores from S3. After performing one of these types of restores, you can re-enable CDC and re-specify tables to track.

To enable CDC for a DB instance, run the `msdb.dbo.rds_cdc_enable_db` stored procedure.

```
exec msdb.dbo.rds_cdc_enable_db 'database_name'
```

To disable CDC for a DB instance, run the `msdb.dbo.rds_cdc_disable_db` stored procedure.

```
exec msdb.dbo.rds_cdc_disable_db 'database_name'
```

Topics

- [Tracking tables with change data capture \(p. 820\)](#)
- [Change data capture jobs \(p. 821\)](#)
- [Change data capture for Multi-AZ instances \(p. 821\)](#)

Tracking tables with change data capture

After CDC is enabled on the database, you can start tracking specific tables. You can choose the tables to track by running [`sys.sp_cdc_enable_table`](#).

```
--Begin tracking a table
```

```
exec sys.sp_cdc_enable_table
    @source_schema      = N'source_schema'
    , @source_name       = N'source_name'
    , @role_name         = N'role_name'

--The following parameters are optional:

--, @capture_instance     = 'capture_instance'
--, @supports_net_changes = supports_net_changes
--, @index_name           = 'index_name'
--, @captured_column_list = 'captured_column_list'
--, @filegroup_name        = 'filegroup_name'
--, @allow_partition_switch = 'allow_partition_switch'
;
```

To view the CDC configuration for your tables, run [sys.sp_cdc_help_change_data_capture](#).

```
--View CDC configuration
exec sys.sp_cdc_help_change_data_capture

--The following parameters are optional and must be used together.
--  'schema_name', 'table_name'
;
```

For more information on CDC tables, functions, and stored procedures in SQL Server documentation, see the following:

- [Change data capture stored procedures \(Transact-SQL\)](#)
- [Change data capture functions \(Transact-SQL\)](#)
- [Change data capture tables \(Transact-SQL\)](#)

Change data capture jobs

When you enable CDC, SQL Server creates the CDC jobs. Database owners (`db_owner`) can view, create, modify, and delete the CDC jobs. However, the RDS system account owns them. Therefore, the jobs aren't visible from native views, procedures, or in SQL Server Management Studio.

To control behavior of CDC in a database, use native SQL Server procedures such as `sp_cdc_enable_table` and `sp_cdc_start_job`. To change CDC job parameters, like `maxtrans` and `maxscans`, you can use `sp_cdc_change_job`.

To get more information regarding the CDC jobs, you can query the following dynamic management views:

- `sys.dm_cdc_errors`
- `sys.dm_cdc_log_scan_sessions`
- `sysjobs`
- `sysjobhistory`

Change data capture for Multi-AZ instances

If you use CDC on a Multi-AZ instance, make sure the mirror's CDC job configuration matches the one on the principal. CDC jobs are mapped to the `database_id`. If the database IDs on the secondary are different from the principal, then the jobs won't be associated with the correct database. To try to prevent errors after failover, RDS drops and recreates the jobs on the new principal. The recreated jobs use the parameters that the principal recorded before failover.

Although this process runs quickly, it's still possible that the CDC jobs might run before RDS can correct them. Here are three ways to force parameters to be consistent between primary and secondary replicas:

- Use the same job parameters for all the databases that have CDC enabled.
- Before you change the CDC job configuration, convert the Multi-AZ instance to Single-AZ.
- Manually transfer the parameters whenever you change them on the principal.

To view and define the CDC parameters that are used to recreate the CDC jobs after a failover, use `rds_show_configuration` and `rds_set_configuration`.

The following example returns the value set for `cdc_capture_maxtrans`. For any parameter that is set to `RDS_DEFAULT`, RDS automatically configures the value.

```
-- Show configuration for each parameter on either primary and secondary replicas.  
exec rdsadmin.dbo.rds_show_configuration 'cdc_capture_maxtrans'
```

To set the configuration on the secondary, run `rdsadmin.dbo.rds_set_configuration`. This procedure sets the parameter values for all of the databases on the secondary server. These settings are used only after a failover. The following example sets the `maxtrans` for all CDC capture jobs to `1000`:

```
--To set values on secondary. These are used after failover.  
exec rdsadmin..rds_set_configuration 'cdc_capture_maxtrans' , 1000
```

To set the CDC job parameters on the principal, use `sys.sp_cdc_change_job` instead.

Using SQL Server Agent

With Amazon RDS, you can use SQL Server Agent on a DB instance running Microsoft SQL Server Standard, Web Edition, or Enterprise Edition. SQL Server Agent is a Microsoft Windows service that runs scheduled administrative tasks, which are called jobs. You can use SQL Server Agent to run T-SQL jobs to rebuild indexes, run corruption checks, and aggregate data in a SQL Server DB instance.

SQL Server Agent can run a job on a schedule, in response to a specific event, or on demand. For more information, see [SQL Server Agent](#) in the SQL Server documentation. You should avoid scheduling jobs to run during the maintenance and backup windows for your DB instance because these maintenance and backup processes that are launched by AWS could interrupt the job or cause it to be cancelled. Because Amazon RDS backs up your DB instance, you do not use SQL Server Agent to create backups.

To view the history of an individual SQL Server Agent job in the SQL Server Management Studio, you open Object Explorer, right-click the job, and then click **View History**.

Because SQL Server Agent is running on a managed host in a DB instance, there are some actions that are not supported. Running replication jobs and running command-line scripts by using ActiveX, Windows command shell, or Windows PowerShell are not supported. In addition, you cannot manually start, stop, or restart SQL Server Agent because its operation is managed by the host. Email notifications through SQL Server Agent are not available from a DB instance.

When you create a SQL Server DB instance, the master user name is enrolled in the `SQLAgentUserRole` role. To allow an additional login/user to use SQL Server Agent, you must log in as the master user and do the following.

1. Create another server-level login by using the `CREATE LOGIN` command.
2. Create a user in `msdb` using `CREATE USER` command, and then link this user to the login that you created in the previous step.
3. Add the user to the `SQLAgentUserRole` using the `sp_addrolemember` system stored procedure.

For example, suppose your master user name is **admin** and you want to give access to SQL Server Agent to a user named **theirname** with a password **theirpassword**. You would log in using the master user name and run the following commands.

```
--Initially set context to master database
USE [master];
GO
--Create a server-level login named theirname with password theirpassword
CREATE LOGIN [theirname] WITH PASSWORD = 'theirpassword';
GO
--Set context to msdb database
USE [msdb];
GO
--Create a database user named theirname and link it to server-level login theirname
CREATE USER [theirname] FOR LOGIN [theirname];
GO
--Added database user theirname in msdb to SQLAgentUserRole in msdb
EXEC sp_addrolemember [SQLAgentUserRole], [theirname];
```

To delete a SQL Server Agent job, run the following T-SQL statement.

```
EXEC msdb..sp_delete_job @job_name = 'job_name';
```

Note

Don't use the UI in SQL Server Management Console (SSMS) to delete a SQL Server Agent job. If you do, you get an error message similar to the following:

```
The EXECUTE permission was denied on the object 'xp_regrid', database
'mssqlsystemresource', schema 'sys'.
```

This error occurs because, as a managed service, RDS is restricted from running procedures that access the Windows registry. When you use SSMS to delete the job, it tries to run a process (*xp_regrid*) that RDS isn't authorized to do.

Working with Microsoft SQL Server logs

You can use the Amazon RDS console to view, watch, and download SQL Server Agent logs and Microsoft SQL Server error logs.

Watching log files

If you view a log in the Amazon RDS console, you can see its contents as they exist at that moment. Watching a log in the console opens it in a dynamic state so that you can see updates to it in near-real time.

Only the latest log is active for watching. For example, suppose you have the following logs shown:

Name	Last Written	Size	view	watch	download
log/ERROR	January 14, 2015 at 5:17:35 AM UTC-8	6.1 kB	view	watch	download
log/ERROR.1	January 13, 2015 at 3:59:00 PM UTC-8	53.3 kB	view	watch	download
log/ERROR.2	January 12, 2015 at 3:59:00 PM UTC-8	5.9 kB	view	watch	download
log/ERROR.3	January 11, 2015 at 3:59:00 PM UTC-8	5.9 kB	view	watch	download
log/ERROR.4	January 10, 2015 at 3:59:00 PM UTC-8	5.9 kB	view	watch	download

Only log/ERROR, as the most recent log, is being actively updated. You can choose to watch others, but they are static and will not update.

Archiving log files

The Amazon RDS console shows logs for the past week through the current day. You can download and archive logs to keep them for reference past that time. One way to archive logs is to load them into an Amazon S3 bucket. For instructions on how to set up an Amazon S3 bucket and upload a file, see [Amazon S3 basics](#) in the *Amazon Simple Storage Service Getting Started Guide* and click **Get Started**.

Viewing error and agent logs

To view Microsoft SQL Server error and agent logs, use the Amazon RDS stored procedure `rds_read_error_log` with the following parameters:

- `@index` – the version of the log to retrieve. The default value is 0, which retrieves the current error log. Specify 1 to retrieve the previous log, specify 2 to retrieve the one before that, and so on.
- `@type` – the type of log to retrieve. Specify 1 to retrieve an error log. Specify 2 to retrieve an agent log.

Example

The following example requests the current error log.

```
EXEC rdsadmin.dbo.rds_read_error_log @index = 0, @type = 1;
```

For more information on SQL Server errors, see [Database engine errors](#) in the Microsoft documentation.

Working with trace and dump files

This section describes working with trace files and dump files for your Amazon RDS DB instances running Microsoft SQL Server.

Generating a trace SQL query

```
declare @rc int
declare @TraceID int
declare @maxfilesize bigint

set @maxfilesize = 5

exec @rc = sp_trace_create @TraceID output, 0, N'D:\rdsdbdata\log\rdstest', @maxfilesize,
NULL
```

Viewing an open trace

```
select * from ::fn_trace_getinfo(default)
```

Viewing trace contents

```
select * from ::fn_trace_gettable('D:\rdsdbdata\log\rdstest.trc', default)
```

Setting the retention period for trace and dump files

Trace and dump files can accumulate and consume disk space. By default, Amazon RDS purges trace and dump files that are older than seven days.

To view the current trace and dump file retention period, use the `rds_show_configuration` procedure, as shown in the following example.

```
exec rdsadmin..rds_show_configuration;
```

To modify the retention period for trace files, use the `rds_set_configuration` procedure and set the `tracefile retention` in minutes. The following example sets the trace file retention period to 24 hours.

```
exec rdsadmin..rds_set_configuration 'tracefile retention', 1440;
```

To modify the retention period for dump files, use the `rds_set_configuration` procedure and set the `dumpfile retention` in minutes. The following example sets the dump file retention period to 3 days.

```
exec rdsadmin..rds_set_configuration 'dumpfile retention', 4320;
```

For security reasons, you cannot delete a specific trace or dump file on a SQL Server DB instance. To delete all unused trace or dump files, set the retention period for the files to 0.

MySQL on Amazon RDS

Amazon RDS supports DB instances running several versions of MySQL. You can use the following major versions:

- MySQL 8.0
- MySQL 5.7
- MySQL 5.6
- MySQL 5.5

For more information about minor version support, see [MySQL on Amazon RDS versions \(p. 828\)](#).

You first use the Amazon RDS management tools or interfaces to create an RDS for MySQL DB instance. You can then resize the DB instance, authorize connections to the DB instance, create and restore from backups or snapshots, create Multi-AZ secondaries, create read replicas, and monitor the performance of the DB instance. You use standard MySQL utilities and applications to store and access the data in the DB instance.

Amazon RDS for MySQL is compliant with many industry standards. For example, you can use Amazon RDS for MySQL databases to build HIPAA-compliant applications and to store healthcare related information, including protected health information (PHI) under a Business Associate Agreement (BAA) with AWS. Amazon RDS for MySQL also meets Federal Risk and Authorization Management Program (FedRAMP) security requirements and has received a FedRAMP Joint Authorization Board (JAB) Provisional Authority to Operate (P-ATO) at the FedRAMP HIGH Baseline within the AWS GovCloud (US) Regions. For more information on supported compliance standards, see [AWS cloud compliance](#).

For information about the features in each version of MySQL, see [The main features of MySQL](#) in the MySQL documentation.

Common management tasks for MySQL on Amazon RDS

The following are the common management tasks you perform with an RDS for MySQL DB instance, with links to relevant documentation for each task.

Task area	Relevant documentation
Understanding Amazon RDS Understand key Amazon RDS components, including DB instances, AWS Regions, Availability Zones, security groups, parameter groups, and option groups.	What is Amazon Relational Database Service (Amazon RDS)? (p. 1)
Setting up Amazon RDS for first time use Set up Amazon RDS so that you can create MySQL DB instances in Amazon Web Services (AWS).	Setting up for Amazon RDS (p. 67)
Understanding Amazon RDS DB instances	Amazon RDS DB instances (p. 5)

Task area	Relevant documentation
<p>Create virtual MySQL server instances that run in AWS. Because DB instances are the building blocks of Amazon RDS, we recommend that you understand their principles.</p>	
<p>Creating a DB instance for production</p> <p>Create a DB instance for production purposes. Creating an instance includes choosing a DB instance class with appropriate processing power and memory capacity and choosing a storage type that supports the way you expect to use your database.</p>	<p>DB instance classes (p. 7)</p> <p>Amazon RDS storage types (p. 40)</p> <p>Creating an Amazon RDS DB instance (p. 141)</p>
<p>Managing security for your DB instance</p> <p>By default, DB instances are created with a firewall that prevents access to them. You must create a security group with the correct IP addresses and network configuration to access the DB instance. You can also use AWS Identity and Access Management (IAM) policies to assign permissions that determine who is allowed to manage RDS resources.</p>	<p>Security in Amazon RDS (p. 1627)</p> <p>Managing access using policies (p. 1646)</p> <p>Controlling access with security groups (p. 1699)</p> <p>Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1718)</p>
<p>Connecting to your DB instance</p> <p>Connect to your DB instance using a standard SQL client application such as the MySQL command line utility or MySQL Workbench.</p>	<p>Connecting to a DB instance running the MySQL database engine (p. 840)</p>
<p>Configuring high availability for a production DB instance</p> <p>Provide high availability with synchronous standby replication in a different Availability Zone, automatic failover, fault tolerance for DB instances using Multi-AZ deployments, and read replicas.</p>	<p>High availability (Multi-AZ) for Amazon RDS (p. 53)</p>
<p>Configuring a DB instance in an Amazon Virtual Private Cloud</p> <p>Configure a virtual private cloud (VPC) in the Amazon VPC service. An Amazon VPC is a virtual network logically isolated from other virtual networks in AWS.</p>	<p>Determining whether you are using the EC2-VPC or EC2-Classic platform (p. 1718)</p> <p>Working with a DB instance in a VPC (p. 1727)</p>
<p>Configuring specific MySQL database parameters and features</p> <p>Configure specific MySQL database parameters with a parameter group that can be associated with many DB instances. You can also configure specific MySQL database features with an option group that can be associated with many DB instances.</p>	<p>Working with DB parameter groups (p. 228)</p> <p>Working with option groups (p. 212)</p> <p>Options for MySQL DB instances (p. 925)</p>

Task area	Relevant documentation
Modifying a DB instance running the MySQL database engine Change the settings of a DB instance to accomplish tasks such as adding additional storage or changing the DB instance class.	Modifying an Amazon RDS DB instance (p. 250)
Configuring database backup and restore Configure your DB instance to take automated backups. You can also back up and restore your databases manually by using full backup files.	Working with backups (p. 328) Backing up and restoring an Amazon RDS DB instance (p. 327)
Importing and exporting data Import data from other MySQL DB instances, MySQL instances running external to Amazon RDS, and other types of data sources, and export data to MySQL instances running external to Amazon RDS.	Restoring a backup into a MySQL DB instance (p. 871)
Monitoring a MySQL DB instance Monitor your MySQL DB instance by using Amazon CloudWatch RDS metrics, events, and Enhanced Monitoring. View log files for your MySQL DB instance.	Monitoring an Amazon RDS DB instance (p. 399) Viewing DB instance metrics (p. 548) Viewing Amazon RDS events (p. 503) Accessing Amazon RDS database log files (p. 504) Accessing MySQL database log files (p. 519)
Replicating your data Create a MySQL read replica, in the same AWS Region or a different one. You can use read replicas for load balancing, disaster recovery, and processing read-heavy database workloads, such as for analysis and reporting.	Working with read replicas (p. 278) Replication with a MySQL or MariaDB instance running external to Amazon RDS (p. 914)

There are also several sections with useful information about working with MySQL DB instances:

- [Common DBA tasks for MySQL DB instances \(p. 933\)](#)
- [Options for MySQL DB instances \(p. 925\)](#)
- [MySQL on Amazon RDS SQL reference \(p. 952\)](#)

MySQL on Amazon RDS versions

For MySQL, version numbers are organized as version = X.Y.Z. In Amazon RDS terminology, X.Y denotes the major version, and Z is the minor version number. For Amazon RDS implementations, a version change is considered major if the major version number changes—for example, going from version 5.7 to 8.0. A version change is considered minor if only the minor version number changes—for example, going from version 5.7.16 to 5.7.21.

Amazon RDS currently supports the following versions of MySQL:

Major version	Minor version
MySQL 8.0	<ul style="list-style-type: none">• 8.0.23• 8.0.21• 8.0.20• 8.0.19• 8.0.17• 8.0.16• 8.0.15• 8.0.13• 8.0.11
MySQL 5.7	<ul style="list-style-type: none">• 5.7.33• 5.7.31• 5.7.30• 5.7.28• 5.7.26• 5.7.25• 5.7.24• 5.7.23• 5.7.22• 5.7.21• 5.7.19• 5.7.17• 5.7.16
MySQL 5.6	<ul style="list-style-type: none">• 5.6.51• 5.6.49• 5.6.48• 5.6.46• 5.6.44• 5.6.43• 5.6.41• 5.6.40• 5.6.39• 5.6.37• 5.6.35• 5.6.34
MySQL 5.5	<ul style="list-style-type: none">• 5.5.62• 5.5.61• 5.5.59• 5.5.57• 5.5.54• 5.5.53• 5.5.46

You can specify any currently supported MySQL version when creating a new DB instance. You can specify the major version (such as MySQL 5.7), and any supported minor version for the specified major version. If no version is specified, Amazon RDS defaults to a supported version, typically the most recent version. If a major version is specified but a minor version is not, Amazon RDS defaults to a recent release of the major version you have specified. To see a list of supported versions, as well as defaults for newly created DB instances, use the [describe-db-engine-versions](#) AWS CLI command.

The default MySQL version might vary by AWS Region. To create a DB instance with a specific minor version, specify the minor version during DB instance creation. You can determine the default minor version for an AWS Region using the following AWS CLI command:

```
aws rds describe-db-engine-versions --default-only --engine mysql --engine-version major-engine-version --region region --query "*[].{Engine:Engine,EngineVersion:EngineVersion}" --output text
```

Replace *major-engine-version* with the major engine version, and replace *region* with the AWS Region. For example, the following AWS CLI command returns the default MySQL minor engine version for the 5.7 major version and the US West (Oregon) AWS Region (us-west-2):

```
aws rds describe-db-engine-versions --default-only --engine mysql --engine-version 5.7 --region us-west-2 --query '*[].{Engine:Engine,EngineVersion:EngineVersion}' --output text
```

With Amazon RDS, you control when to upgrade your MySQL instance to a new major version supported by Amazon RDS. You can maintain compatibility with specific MySQL versions, test new versions with your application before deploying in production, and perform major version upgrades at times that best fit your schedule.

When automatic minor version upgrade is enabled, your DB instance will be upgraded automatically to new MySQL minor versions as they are supported by Amazon RDS. This patching occurs during your scheduled maintenance window. You can modify a DB instance to enable or disable automatic minor version upgrades.

If you opt out of automatically scheduled upgrades, you can manually upgrade to a supported minor version release by following the same procedure as you would for a major version update. For information, see [Upgrading a DB instance engine version \(p. 271\)](#).

Amazon RDS currently supports the major version upgrades from MySQL version 5.5 to version 5.6, from MySQL version 5.6 to version 5.7, and from MySQL version 5.7 to version 8.0. Because major version upgrades involve some compatibility risk, they do not occur automatically; you must make a request to modify the DB instance. You should thoroughly test any upgrade before upgrading your production instances. For information about upgrading a MySQL DB instance, see [Upgrading the MySQL DB engine \(p. 853\)](#).

You can test a DB instance against a new version before upgrading by creating a DB snapshot of your existing DB instance, restoring from the DB snapshot to create a new DB instance, and then initiating a version upgrade for the new DB instance. You can then experiment safely on the upgraded clone of your DB instance before deciding whether or not to upgrade your original DB instance.

Deprecation of MySQL version 5.6

On August 3, 2021, Amazon RDS plans to deprecate support for MySQL 5.6 using the following schedule, which includes upgrade recommendations. For more information, see [Upgrading the MySQL DB engine \(p. 853\)](#).

Action or recommendation	Dates
We recommend that you upgrade MySQL 5.6 DB instances manually to the version of your choice.	Now–August 3, 2021
We recommend that you upgrade MySQL 5.6 snapshots manually to the version of your choice.	Now–August 3, 2021
You can no longer create new MySQL 5.6 DB instances.	April 1, 2021
Amazon RDS starts automatic upgrades of your MySQL 5.6 DB instances to version 5.7.	August 3, 2021
Amazon RDS starts automatic upgrades to version 5.7 for any MySQL 5.6 DB instances restored from snapshots.	August 3, 2021
Amazon RDS automatically upgrades any remaining MySQL 5.6 DB instances to version 5.7 whether or not they are in a maintenance window.	September 1, 2021

For more information, see [Announcement: Amazon Relational Database Service \(RDS\) for MySQL 5.6 End-of-Life date is August 3, 2021](#).

Deprecation of MySQL version 5.5

On May 25, 2021, Amazon RDS plans to deprecate support for MySQL 5.5 using the following schedule, which includes upgrade recommendations. For more information, see [Upgrading the MySQL DB engine \(p. 853\)](#).

Action or recommendation	Dates
We recommend that you upgrade MySQL 5.5 DB instances manually to the version of your choice.	Now–May 25, 2021
We recommend that you upgrade MySQL 5.5 snapshots manually to the version of your choice.	Now–May 25, 2021
You can no longer create new MySQL 5.5 DB instances.	December 3, 2020
Amazon RDS starts automatic upgrades of your MySQL 5.5 DB instances to version 5.6.	March 29, 2021
Amazon RDS starts automatic upgrades to version 5.6 for any MySQL 5.5 DB instances restored from snapshots.	March 29, 2021
Amazon RDS automatically upgrades any remaining MySQL 5.5 DB instances to version 5.6 whether or not they are in a maintenance window.	May 25, 2021

For more information, see [Announcement: Extending end-of-life process for Amazon RDS for MySQL 5.5](#).

MySQL features not supported by Amazon RDS

Amazon RDS doesn't currently support the following MySQL features:

- Authentication Plugin
- Error Logging to the System Log
- Group Replication Plugin
- InnoDB Tablespace Encryption
- MariaDB Audit Plugin (not supported for RDS for MySQL version 8.0 only)

The MariaDB Audit Plugin is supported for RDS for MySQL version 5.5, 5.6, and 5.7.

- Password Strength Plugin
- Persisted system variables
- Semisynchronous replication
- Transportable tablespace
- X Plugin

Note

Global transaction IDs are supported for MySQL 5.7.23 and later MySQL 5.7 versions. Global transaction IDs are not supported for RDS for MySQL 5.5, 5.6, or 8.0.

IAM database authentication is supported for MySQL for MySQL 5.6, 5.7, and 8.0. IAM database authentication is not supported for MySQL 5.5.

Amazon RDS Performance Insights is supported for MySQL 5.6, 5.7, and 8.0. Amazon RDS Performance Insights is not supported for MySQL 5.5.

To deliver a managed service experience, Amazon RDS doesn't provide shell access to DB instances. It also restricts access to certain system procedures and tables that require advanced privileges. Amazon RDS supports access to databases on a DB instance using any standard SQL client application. Amazon RDS doesn't allow direct host access to a DB instance by using Telnet, Secure Shell (SSH), or Windows Remote Desktop Connection. When you create a DB instance, you are assigned to the *db_owner* role for all databases on that instance, and you have all database-level permissions except for those used for backups. Amazon RDS manages backups for you.

Supported storage engines for MySQL on Amazon RDS

While MySQL supports multiple storage engines with varying capabilities, not all of them are optimized for recovery and data durability. Amazon RDS fully supports the InnoDB storage engine for MySQL DB instances. Amazon RDS features such as Point-In-Time restore and snapshot restore require a recoverable storage engine and are supported for the InnoDB storage engine only. You must be running an instance of MySQL 5.6 or later to use the InnoDB memcached interface. For more information, see [MySQL memcached support \(p. 929\)](#).

The Federated Storage Engine is currently not supported by Amazon RDS for MySQL.

For user-created schemas, the MyISAM storage engine does not support reliable recovery and can result in lost or corrupt data when MySQL is restarted after a recovery, preventing Point-In-Time restore or snapshot restore from working as intended. However, if you still choose to use MyISAM with Amazon RDS, snapshots can be helpful under some conditions.

Note

System tables in the `mysql` schema can be in MyISAM storage.

If you want to convert existing MyISAM tables to InnoDB tables, you can use the `ALTER TABLE` command (for example, `alter table TABLE_NAME engine=innodb;`). Bear in mind that MyISAM and InnoDB have different strengths and weaknesses, so you should fully evaluate the impact of making this switch on your applications before doing so.

MySQL 5.1 is no longer supported in Amazon RDS. However, you can restore existing MySQL 5.1 snapshots. When you restore a MySQL 5.1 snapshot, the instance is automatically upgraded to MySQL 5.5.

MySQL security on Amazon RDS

Security for MySQL DB instances is managed at three levels:

- AWS Identity and Access Management controls who can perform Amazon RDS management actions on DB instances. When you connect to AWS using IAM credentials, your IAM account must have IAM policies that grant the permissions required to perform Amazon RDS management operations. For more information, see [Identity and access management in Amazon RDS \(p. 1644\)](#).
- When you create a DB instance, you use either a VPC security group or a DB security group to control which devices and Amazon EC2 instances can open connections to the endpoint and port of the DB instance. These connections can be made using Secure Sockets Layer (SSL). In addition, firewall rules at your company can control whether devices running at your company can open connections to the DB instance.
- To authenticate login and permissions for a MySQL DB instance, you can take either of the following approaches, or a combination of them.

You can take the same approach as with a stand-alone instance of MySQL. Commands such as `CREATE USER`, `RENAME USER`, `GRANT`, `REVOKE`, and `SET PASSWORD` work just as they do in on-premises databases, as does directly modifying database schema tables. For information, see [Access control and account management](#) in the MySQL documentation.

You can also use IAM database authentication. With IAM database authentication, you authenticate to your DB instance by using an IAM user or IAM role and an authentication token. An *authentication token* is a unique value that is generated using the Signature Version 4 signing process. By using IAM database authentication, you can use the same credentials to control access to your AWS resources and your databases. For more information, see [IAM database authentication for MySQL and PostgreSQL \(p. 1660\)](#).

When you create an Amazon RDS DB instance, the master user has the following default privileges:

- `alter`
- `alter routine`
- `create`
- `create routine`
- `create temporary tables`
- `create user`
- `create view`
- `delete`
- `drop`

- event
- execute
- grant option
- index
- insert
- lock tables
- process
- references
- replication client
- replication slave (MySQL 5.6 and later)
- select
- show databases
- show view
- trigger
- update

Note

Although it is possible to delete the master user on the DB instance, it is not recommended. To recreate the master user, use the [ModifyDBInstance](#) RDS API operation or the [modify-db-instance](#) AWS CLI command and specify a new master user password with the appropriate parameter. If the master user does not exist in the instance, the master user is created with the specified password.

To provide management services for each DB instance, the `rdsadmin` user is created when the DB instance is created. Attempting to drop, rename, change the password, or change privileges for the `rdsadmin` account will result in an error.

To allow management of the DB instance, the standard `kill` and `kill_query` commands have been restricted. The Amazon RDS commands `rds_kill` and `rds_kill_query` are provided to allow you to end user sessions or queries on DB instances.

Using the Password Validation Plugin

MySQL provides the `validate_password` plugin for improved security. The plugin enforces password policies using parameters in the DB parameter group for your MySQL DB instance. The plugin is supported for DB instances running MySQL version 5.6, 5.7, and 8.0. For more information about the `validate_password` plugin, see [The Password Validation Plugin](#) in the MySQL documentation.

To enable the `validate_password` plugin for a MySQL DB instance

1. Connect to your MySQL DB instance and run the following command.

```
INSTALL PLUGIN validate_password SONAME 'validate_password.so';
```

2. Configure the parameters for the plugin in the DB parameter group used by the DB instance.

For more information about the parameters, see [Password Validation Plugin options and variables](#) in the MySQL documentation.

For more information about modifying DB instance parameters, see [Modifying parameters in a DB parameter group \(p. 232\)](#).

After installing and enabling the `password_validate` plugin, reset existing passwords to comply with your new validation policies.

Amazon RDS doesn't validate passwords. The MySQL DB instance performs password validation. If you set a user password with the AWS Management Console, the `modify-db-instance` AWS CLI command, or the `ModifyDBInstance` RDS API operation, the change can succeed even if the new password doesn't satisfy your password policies. However, a new password is set in the MySQL DB instance only if it satisfies the password policies. In this case, Amazon RDS records the following event.

```
"RDS-EVENT-0067" - An attempt to reset the master password for the DB instance has failed.
```

For more information about Amazon RDS events, see [Using Amazon RDS event notification \(p. 487\)](#).

Using SSL with a MySQL DB instance

Amazon RDS supports Secure Sockets Layer (SSL) connections with DB instances running the MySQL database engine.

Amazon RDS creates an SSL certificate and installs the certificate on the DB instance when Amazon RDS provisions the instance. These certificates are signed by a certificate authority. The SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks.

An SSL certificate created by Amazon RDS is the trusted root entity and should work in most cases but might fail if your application does not accept certificate chains. If your application does not accept certificate chains, you might need to use an intermediate certificate to connect to your AWS Region. For example, you must use an intermediate certificate to connect to the AWS GovCloud (US) Regions using SSL.

For information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 1634\)](#). For more information about using SSL with MySQL, see [Updating applications to connect to MySQL DB instances using new SSL/TLS certificates \(p. 848\)](#).

MySQL uses yaSSL for secure connections in the following versions:

- MySQL version 5.7.19 and earlier 5.7 versions
- MySQL version 5.6.37 and earlier 5.6 versions
- MySQL version 5.5.57 and earlier 5.5 versions

MySQL uses OpenSSL for secure connections in the following versions:

- MySQL version 8.0
- MySQL version 5.7.21 and later 5.7 versions
- MySQL version 5.6.39 and later 5.6 versions
- MySQL version 5.5.59 and later 5.5 versions

Amazon RDS for MySQL supports Transport Layer Security (TLS) versions 1.0, 1.1, and 1.2. The following table shows the TLS support for MySQL versions.

MySQL version	TLS 1.0	TLS 1.1	TLS 1.2
MySQL 8.0	Supported	Supported	Supported
MySQL 5.7	Supported	Supported	Supported for MySQL 5.7.21 and later
MySQL 5.6	Supported	Supported for MySQL 5.6.46 and later	Supported for MySQL 5.6.46 and later
MySQL 5.5	Supported	Not supported	Not supported

To encrypt connections using the default `mysql` client, launch the `mysql` client using the `--ssl-ca` parameter to reference the public key, as shown in the examples following.

The following example shows how to launch the client using the `--ssl-ca` parameter for MySQL 5.7 and later.

```
mysql -h myinstance.c9akciq32.rds-us-east-1.amazonaws.com
--ssl-ca=[full path]rds-combined-ca-bundle.pem --ssl-mode=VERIFY_IDENTITY
```

The following example shows how to launch the client using the `--ssl-ca` parameter for MySQL 5.6 and earlier.

```
mysql -h myinstance.c9akciq32.rds-us-east-1.amazonaws.com
--ssl-ca=[full path]rds-combined-ca-bundle.pem --ssl-verify-server-cert
```

You can require SSL connections for specific user accounts. For example, you can use one of the following statements, depending on your MySQL version, to require SSL connections on the user account `encrypted_user`.

For MySQL 5.7 and later, use the following statement.

```
ALTER USER 'encrypted_user'@'%' REQUIRE SSL;
```

For MySQL 5.6 and earlier, use the following statement.

```
GRANT USAGE ON *.* TO 'encrypted_user'@'%' REQUIRE SSL;
```

For more information on SSL connections with MySQL, see the [Using encrypted connections](#) in the MySQL documentation.

Using memcached and other options with MySQL

Most Amazon RDS DB engines support option groups that allow you to select additional features for your DB instance. DB instances on MySQL version 5.6 and later support the `memcached` option, a simple,

key-based cache. For more information about memcached and other options, see [Options for MySQL DB instances \(p. 925\)](#). For more information about working with option groups, see [Working with option groups \(p. 212\)](#).

InnoDB cache warming

InnoDB cache warming can provide performance gains for your MySQL DB instance by saving the current state of the buffer pool when the DB instance is shut down, and then reloading the buffer pool from the saved information when the DB instance starts up. This bypasses the need for the buffer pool to "warm up" from normal database use and instead preloads the buffer pool with the pages for known common queries. The file that stores the saved buffer pool information only stores metadata for the pages that are in the buffer pool, and not the pages themselves. As a result, the file does not require much storage space. The file size is about 0.2 percent of the cache size. For example, for a 64 GiB cache, the cache warming file size is 128 MiB. For more information on InnoDB cache warming, see [Saving and restoring the buffer pool state](#) in the MySQL documentation.

MySQL on Amazon RDS supports InnoDB cache warming for MySQL version 5.6 and later. To enable InnoDB cache warming, set the `innodb_buffer_pool_dump_at_shutdown` and `innodb_buffer_pool_load_at_startup` parameters to 1 in the parameter group for your DB instance. Changing these parameter values in a parameter group will affect all MySQL DB instances that use that parameter group. To enable InnoDB cache warming for specific MySQL DB instances, you might need to create a new parameter group for those instances. For information on parameter groups, see [Working with DB parameter groups \(p. 228\)](#).

InnoDB cache warming primarily provides a performance benefit for DB instances that use standard storage. If you use PIOPS storage, you do not commonly see a significant performance benefit.

Important

If your MySQL DB instance does not shut down normally, such as during a failover, then the buffer pool state will not be saved to disk. In this case, MySQL loads whatever buffer pool file is available when the DB instance is restarted. No harm is done, but the restored buffer pool might not reflect the most recent state of the buffer pool prior to the restart. To ensure that you have a recent state of the buffer pool available to warm the InnoDB cache on startup, we recommend that you periodically dump the buffer pool "on demand." You can dump or load the buffer pool on demand if your DB instance is running MySQL version 5.6.19 or later.

You can create an event to dump the buffer pool automatically and on a regular interval. For example, the following statement creates an event named `periodic_buffer_pool_dump` that dumps the buffer pool every hour.

```
CREATE EVENT periodic_buffer_pool_dump
ON SCHEDULE EVERY 1 HOUR
DO CALL mysql.rds_innodb_buffer_pool_dump_now();
```

For more information on MySQL events, see [Event syntax](#) in the MySQL documentation.

Dumping and loading the buffer pool on demand

For MySQL version 5.6.19 and later, you can save and load the InnoDB cache "on demand."

- To dump the current state of the buffer pool to disk, call the [mysql.rds_innodb_buffer_pool_dump_now \(p. 971\)](#) stored procedure.
- To load the saved state of the buffer pool from disk, call the [mysql.rds_innodb_buffer_pool_load_now \(p. 971\)](#) stored procedure.
- To cancel a load operation in progress, call the [mysql.rds_innodb_buffer_pool_load_abort \(p. 972\)](#) stored procedure.

Local time zone for MySQL DB instances

By default, the time zone for a MySQL DB instance is Universal Time Coordinated (UTC). You can set the time zone for your DB instance to the local time zone for your application instead.

To set the local time zone for a DB instance, set the `time_zone` parameter in the parameter group for your DB instance to one of the supported values listed later in this section. When you set the `time_zone` parameter for a parameter group, all DB instances and read replicas that are using that parameter group change to use the new local time zone. For information on setting parameters in a parameter group, see [Working with DB parameter groups \(p. 228\)](#).

After you set the local time zone, all new connections to the database reflect the change. If you have any open connections to your database when you change the local time zone, you won't see the local time zone update until after you close the connection and open a new connection.

You can set a different local time zone for a DB instance and one or more of its read replicas. To do this, use a different parameter group for the DB instance and the replica or replicas and set the `time_zone` parameter in each parameter group to a different local time zone.

If you are replicating across AWS Regions, then the source DB instance and the read replica use different parameter groups (parameter groups are unique to an AWS Region). To use the same local time zone for each instance, you must set the `time_zone` parameter in the instance's and read replica's parameter groups.

When you restore a DB instance from a DB snapshot, the local time zone is set to UTC. You can update the time zone to your local time zone after the restore is complete. If you restore a DB instance to a point in time, then the local time zone for the restored DB instance is the time zone setting from the parameter group of the restored DB instance.

You can set your local time zone to one of the following values.

Africa/Cairo	Asia/Bangkok	Australia/Darwin
Africa/Casablanca	Asia/Beirut	Australia/Hobart

Known issues and limitations for MySQL on Amazon RDS

There are some known issues and limitations for working with MySQL on Amazon RDS. For more information, see [Known issues and limitations for MySQL on Amazon RDS \(p. 948\)](#).

Deprecated MySQL on Amazon RDS versions

MySQL on Amazon RDS version 5.1 is deprecated.

For information about the Amazon RDS deprecation policy for MySQL, see [Amazon RDS FAQs](#).

Connecting to a DB instance running the MySQL database engine

Before you can connect to a DB instance running the MySQL database engine, you must create a DB instance. For information, see [Creating an Amazon RDS DB instance \(p. 141\)](#). After Amazon RDS provisions your DB instance, you can use any standard MySQL client application or utility to connect to the instance. In the connection string, you specify the DNS address from the DB instance endpoint as the host parameter, and specify the port number from the DB instance endpoint as the port parameter.

To authenticate to your RDS DB instance, you can use one of the authentication methods for MySQL and AWS Identity and Access Management (IAM) database authentication:

- To learn how to authenticate to MySQL using one of the authentication methods for MySQL, see [Authentication method](#) in the MySQL documentation.
- To learn how to authenticate to MySQL using IAM database authentication, see [IAM database authentication for MySQL and PostgreSQL \(p. 1660\)](#).

You can connect to a MySQL DB instance by using tools like the MySQL command line utility. For more information on using the MySQL client, see [mysql - the MySQL command-line client](#) in the MySQL documentation. One GUI-based application you can use to connect is MySQL Workbench. For more information, see the [Download MySQL Workbench](#) page. For information about installing MySQL (including the MySQL client), see [Installing and upgrading MySQL](#).

To connect to a DB instance from outside of its Amazon VPC, the DB instance must be publicly accessible, access must be granted using the inbound rules of the DB instance's security group, and other requirements must be met. For more information, see [Can't connect to Amazon RDS DB instance \(p. 1746\)](#).

You can use Secure Sockets Layer (SSL) encryption on connections to a MySQL DB instance. For information, see [Using SSL with a MySQL DB instance \(p. 835\)](#). If you are using AWS Identity and Access Management (IAM) database authentication, make sure to use an SSL connection. For information, see [IAM database authentication for MySQL and PostgreSQL \(p. 1660\)](#).

You can also connect to a DB instance from a web server. For more information, see [Tutorial: Create a web server and an Amazon RDS DB instance \(p. 108\)](#).

Note

For information on connecting to a MariaDB DB instance, see [Connecting to a DB instance running the MariaDB database engine \(p. 588\)](#).

Topics

- [Finding the connection information for a MySQL DB instance \(p. 840\)](#)
- [Connecting from the MySQL client \(p. 843\)](#)
- [Connecting with SSL \(p. 844\)](#)
- [Connecting from MySQL Workbench \(p. 844\)](#)
- [Troubleshooting connections to your MySQL DB instance \(p. 846\)](#)

Finding the connection information for a MySQL DB instance

The connection information for a DB instance includes its endpoint, port, and a valid database user, such as the master user. For example, suppose that an endpoint value is `mydb.123456789012.us-`

`east-1.rds.amazonaws.com`. In this case, the port value is 3306, and the database user is `admin`. Given this information, you specify the following values in a connection string:

- For host or host name or DNS name, specify `mydb.123456789012.us-east-1.rds.amazonaws.com`.
- For port, specify 3306.
- For user, specify `admin`.

To connect to a DB instance, use any client for a DB engine. For example, you might use the `mysql` utility to connect to a MariaDB or MySQL DB instance. You might use Microsoft SQL Server Management Studio to connect to a SQL Server DB instance. You might use Oracle SQL Developer to connect to an Oracle DB instance, or the `psql` command line utility to connect to a PostgreSQL DB instance.

To find the connection information for a DB instance, you can use the AWS Management Console, the AWS CLI `describe-db-instances` command, or the Amazon RDS API `DescribeDBInstances` operation to list its details.

Console

To find the connection information for a DB instance in the AWS Management Console

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Databases** to display a list of your DB instances.
3. Choose the name of the MySQL DB instance to display its details.
4. On the **Connectivity & security** tab, copy the endpoint. Also, note the port number. You need both the endpoint and the port number to connect to the DB instance.

The screenshot shows the AWS RDS console for a database named 'mydb'. The 'Summary' tab is selected, displaying basic information like DB identifier, Role, and instance status. Below it, the 'Connectivity & security' tab is active, showing the endpoint and port details which are highlighted with red circles.

Category	Value	Notes
DB identifier	mydb	
Role	Instance	
CPU	2.33%	Current activity: 0 Connections
Connectivity & security	Endpoint: mydb. [REDACTED] .us-east-1.rds.amazonaws.com Port: 3306	Network: [REDACTED] , Availability: us-east-1, VPC: vpc-6f..., Subnet: default

5. If you need to find the master user name, choose the **Configuration** tab and view the **Master username** value.

AWS CLI

To find the connection information for a MySQL DB instance by using the AWS CLI, call the [describe-db-instances](#) command. In the call, query for the DB instance ID, endpoint, port, and master user name.

For Linux, macOS, or Unix:

```
aws rds describe-db-instances \
--filters "Name=engine,Values=mysql" \
--query "[].{DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername}"
```

For Windows:

```
aws rds describe-db-instances ^
--filters "Name=engine,Values=mysql" ^
--query "[].{DBInstanceIdentifier,Endpoint.Address,Endpoint.Port,MasterUsername}"
```

Your output should be similar to the following.

```
[  
  [  
    "mydb1",  
    "mydb1.123456789012.us-east-1.rds.amazonaws.com",  
    3306,  
    "admin"  
  ],  
  [  
    "mydb2",  
    "mydb2.123456789012.us-east-1.rds.amazonaws.com",  
    3306,  
    "admin"  
  ]  
]
```

RDS API

To find the connection information for a DB instance by using the Amazon RDS API, call the [DescribeDBInstances](#) operation. In the output, find the values for the endpoint address, endpoint port, and master user name.

Connecting from the MySQL client

To connect to a DB instance using the MySQL client, enter the following command at a command prompt to connect to a DB instance using the MySQL client. For the -h parameter, substitute the DNS name (endpoint) for your DB instance. For the -P parameter, substitute the port for your DB instance. For the -u parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com -P 3306 -u mymasteruser -  
p
```

After you enter the password for the user, you should see output similar to the following.

```
Welcome to the MySQL monitor. Commands end with ; or \g.  
Your MySQL connection id is 350  
Server version: 5.6.40-log MySQL Community Server (GPL)  
  
Type 'help;' or '\h' for help. Type '\c' to clear the buffer.  
  
mysql>
```

Connecting with SSL

Amazon RDS creates an SSL certificate for your DB instance when the instance is created. If you enable SSL certificate verification, then the SSL certificate includes the DB instance endpoint as the Common Name (CN) for the SSL certificate to guard against spoofing attacks. To connect to your DB instance using SSL, you can use native password authentication or IAM database authentication. To connect to your DB instance using IAM database authentication, see [IAM database authentication for MySQL and PostgreSQL \(p. 1660\)](#). To connect to your DB instance using native password authentication, you can follow these steps:

To connect to a DB instance with SSL using the MySQL client

1. Download a root certificate that works for all AWS Regions.

For information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 1634\)](#).

2. Enter the following command at a command prompt to connect to a DB instance with SSL using the MySQL client. For the -h parameter, substitute the DNS name (endpoint) for your DB instance. For the --ssl-ca parameter, substitute the SSL certificate file name as appropriate. For the -P parameter, substitute the port for your DB instance. For the -u parameter, substitute the user name of a valid database user, such as the master user. Enter the master user password when prompted.

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=rds-ca-2015-root.pem -P 3306 -u mymasteruser -p
```

3. You can require that the SSL connection verifies the DB instance endpoint against the endpoint in the SSL certificate.

For MySQL 5.7 and later:

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=rds-ca-2015-root.pem --ssl-mode=VERIFY_IDENTITY -P 3306 -u mymasteruser -p
```

For MySQL 5.6 and earlier:

```
mysql -h mysql-instance1.123456789012.us-east-1.rds.amazonaws.com --ssl-ca=rds-ca-2015-root.pem --ssl-verify-server-cert -P 3306 -u mymasteruser -p
```

4. Enter the master user password when prompted.

You will see output similar to the following.

```
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 350
Server version: 5.6.40-log MySQL Community Server (GPL)

Type 'help;' or '\h' for help. Type '\c' to clear the buffer.

mysql>
```

Connecting from MySQL Workbench

To connect from MySQL Workbench

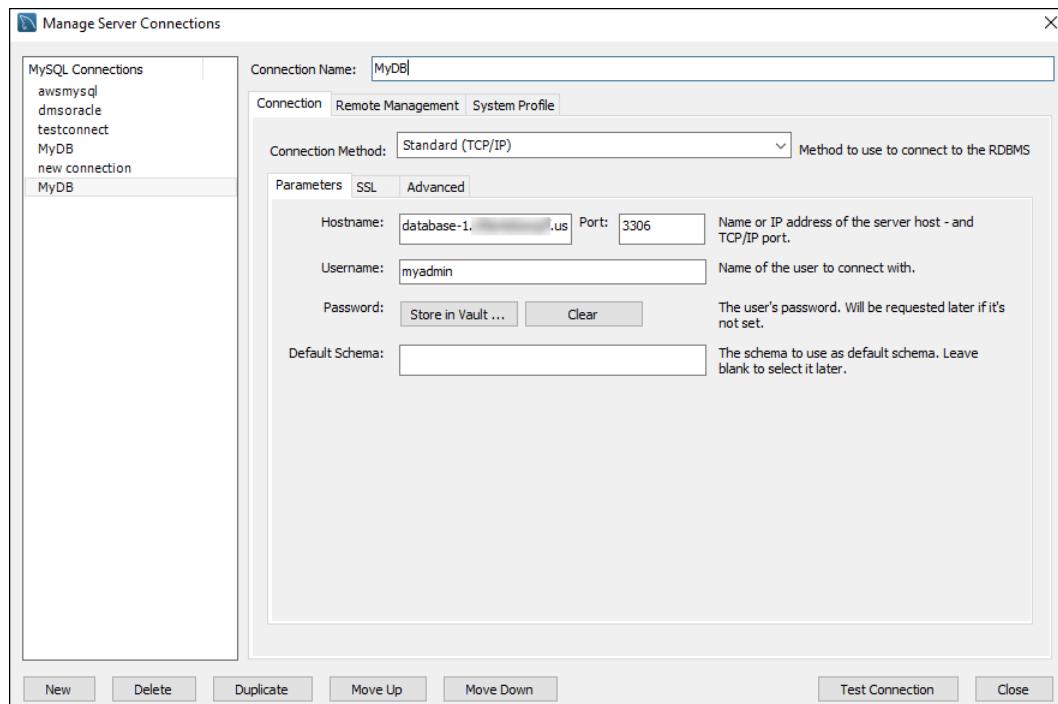

1. Download and install MySQL Workbench at [Download MySQL Workbench](#).

2. Open MySQL Workbench.

3. From **Database**, choose **Manage Connections**.
4. In the **Manage Server Connections** window, choose **New**.
5. In the **Connect to Database** window, enter the following information:
 - **Stored Connection** – Enter a name for the connection, such as **MyDB**.
 - **Hostname** – Enter the DB instance endpoint.
 - **Port** – Enter the port used by the DB instance.
 - **Username** – Enter the user name of a valid database user, such as the master user.
 - **Password** – Optionally, choose **Store in Vault** and then enter and save the password for the user.

The window looks similar to the following:

You can use the features of MySQL Workbench to customize connections. For example, you can use the **SSL** tab to configure SSL connections. For information about using MySQL Workbench, see the [MySQL Workbench documentation](#).

6. Optionally, choose **Test Connection** to confirm that the connection to the DB instance is successful.
7. Choose **Close**.
8. From **Database**, choose **Connect to Database**.
9. From **Stored Connection**, choose your connection.
10. Choose **OK**.

Troubleshooting connections to your MySQL DB instance

Two common causes of connection failures to a new DB instance are:

- The DB instance was created using a security group that doesn't authorize connections from the device or Amazon EC2 instance where the MySQL application or utility is running. If the DB instance was created in a VPC, it must have a VPC security group that authorizes the connections. For more information, see [Amazon Virtual Private Cloud VPCs and Amazon RDS \(p. 1718\)](#).

You can add or edit an inbound rule in the security group. For **Source**, choose **My IP**. This allows access to the DB instance from the IP address detected in your browser.

If the DB instance was created outside of a VPC, it must have a DB security group that authorizes the connections.

- The DB instance was created using the default port of 3306, and your company has firewall rules blocking connections to that port from devices in your company network. To fix this failure, recreate the instance with a different port.

For more information on connection issues, see [Can't connect to Amazon RDS DB instance \(p. 1746\)](#).

Updating applications to connect to MySQL DB instances using new SSL/TLS certificates

As of September 19, 2019, Amazon RDS has published new Certificate Authority (CA) certificates for connecting to your RDS DB instances using Secure Socket Layer or Transport Layer Security (SSL/TLS). Following, you can find information about updating your applications to use the new certificates.

This topic can help you to determine whether any client applications use SSL/TLS to connect to your DB instances. If they do, you can further check whether those applications require certificate verification to connect.

Note

Some applications are configured to connect to MySQL DB instances only if they can successfully verify the certificate on the server. For such applications, you must update your client application trust stores to include the new CA certificates.

You can specify the following SSL modes: `disabled`, `preferred`, and `required`. When you use the `preferred` SSL mode and the CA certificate doesn't exist or isn't up to date, the following behavior applies:

- For newer MySQL minor versions, the connection falls back to not using SSL and still connects successfully.

Because these later versions use the OpenSSL protocol, an expired server certificate doesn't prevent successful connections unless the `required` SSL mode is specified.

The following MySQL minor versions use the OpenSSL protocol:

- All MySQL 8.0 versions
- MySQL 5.7.21 and later MySQL 5.7 versions
- MySQL 5.6.39 and later MySQL 5.6 versions
- MySQL 5.5.59 and later MySQL 5.5 versions
- For older MySQL minor versions, an error is returned.

Because these older versions use the yaSSL protocol, certificate verification is strictly enforced and the connection is unsuccessful.

The following MySQL minor versions use the yaSSL protocol:

- MySQL 5.7.19 and earlier MySQL 5.7 versions
- MySQL 5.6.37 and earlier MySQL 5.6 versions
- MySQL 5.5.57 and earlier MySQL 5.5 versions

After you update your CA certificates in the client application trust stores, you can rotate the certificates on your DB instances. We strongly recommend testing these procedures in a development or staging environment before implementing them in your production environments.

For more information about certificate rotation, see [Rotating your SSL/TLS certificate \(p. 1636\)](#). For more information about downloading certificates, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 1634\)](#). For information about using SSL/TLS with MySQL DB instances, see [Using SSL with a MySQL DB instance \(p. 835\)](#).

Topics

- [Determining whether any applications are connecting to your MySQL DB instance using SSL \(p. 849\)](#)
- [Determining whether a client requires certificate verification to connect \(p. 849\)](#)

- [Updating your application trust store \(p. 850\)](#)
- [Example Java code for establishing SSL connections \(p. 851\)](#)

Determining whether any applications are connecting to your MySQL DB instance using SSL

If you are using Amazon RDS for MySQL version 5.7 or 8.0 and the Performance Schema is enabled, run the following query to check if connections are using SSL/TLS. For information about enabling the Performance Schema, see [Performance Schema quick start](#) in the MySQL documentation.

```
mysql> SELECT id, user, host, connection_type
    FROM performance_schema.threads pst
    INNER JOIN information_schema.processlist isp
    ON pst.processlist_id = isp.id;
```

In this sample output, you can see both your own session (`admin`) and an application logged in as `webapp1` are using SSL.

```
+---+-----+-----+-----+
| id | user           | host          | connection_type |
+---+-----+-----+-----+
|  8 | admin          | 10.0.4.249:42590 | SSL/TLS        |
|  4 | event_scheduler | localhost      | NULL          |
| 10 | webapp1        | 159.28.1.1:42189 | SSL/TLS        |
+---+-----+-----+-----+
3 rows in set (0.00 sec)
```

If you are using Amazon RDS for MySQL versions 5.5 or 5.6, then you can't determine from the server side whether applications are connecting with or without SSL. For those versions, you can determine whether SSL is used by examining the application's connection method. In the following section, you can find more information on examining the client connection configuration.

Determining whether a client requires certificate verification to connect

You can check whether JDBC clients and MySQL clients require certificate verification to connect.

JDBC

The following example with MySQL Connector/J 8.0 shows one way to check an application's JDBC connection properties to determine whether successful connections require a valid certificate. For more information on all of the JDBC connection options for MySQL, see [Configuration properties](#) in the MySQL documentation.

When using the MySQL Connector/J 8.0, an SSL connection requires verification against the server CA certificate if your connection properties have `sslMode` set to `VERIFY_CA` or `VERIFY_IDENTITY`, as in the following example.

```
Properties properties = new Properties();
properties.setProperty("sslMode", "VERIFY_IDENTITY");
properties.put("user", DB_USER);
properties.put("password", DB_PASSWORD);
```

Note

If you use either the MySQL Java Connector v5.1.38 or later, or the MySQL Java Connector v8.0.9 or later to connect to your databases, even if you haven't explicitly configured your applications to use SSL/TLS when connecting to your databases, these client drivers default to using SSL/TLS. In addition, when using SSL/TLS, they perform partial certificate verification and fail to connect if the database server certificate is expired.

MySQL

The following examples with the MySQL Client show two ways to check a script's MySQL connection to determine whether successful connections require a valid certificate. For more information on all of the connection options with the MySQL Client, see [Client-side configuration for encrypted connections](#) in the MySQL documentation.

When using the MySQL 5.7 or MySQL 8.0 Client, an SSL connection requires verification against the server CA certificate if for the --ssl-mode option you specify VERIFY_CA or VERIFY_IDENTITY, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --
ssl-mode=VERIFY_CA
```

When using the MySQL 5.6 Client, an SSL connection requires verification against the server CA certificate if you specify the --ssl-verify-server-cert option, as in the following example.

```
mysql -h mysql-database.rds.amazonaws.com -uadmin -ppassword --ssl-ca=/tmp/ssl-cert.pem --
ssl-verify-server-cert
```

Updating your application trust store

For information about updating the trust store for MySQL applications, see [Installing SSL certificates](#) in the MySQL documentation.

Note

When you update the trust store, you can retain older certificates in addition to adding the new certificates.

Updating your application trust store for JDBC

You can update the trust store for applications that use JDBC for SSL/TLS connections.

To update the trust store for JDBC applications

1. Download the 2019 root certificate that works for all AWS Regions and put the file in the trust store directory.

For information about downloading the root certificate, see [Using SSL/TLS to encrypt a connection to a DB instance \(p. 1634\)](#).

2. Convert the certificate to .der format using the following command.

```
openssl x509 -outform der -in rds-ca-2019-root.pem -out rds-ca-2019-root.der
```

Replace the file name with the one that you downloaded.

3. Import the certificate into the key store using the following command.

```
keytool -import -alias rds-root -keystore clientkeystore -file rds-ca-2019-root.der
```

4. Confirm that the key store was updated successfully.

```
keytool -list -v -keystore clientkeystore.jks
```

Enter the key store password when you are prompted for it.

Your output should contain the following.

```
rds-root, date, trustedCertEntry,  
Certificate fingerprint (SHA1):  
D4:0D:DB:29:E3:75:0D:FF:A6:71:C3:14:0B:BF:5F:47:8D:1C:80:96  
# This fingerprint should match the output from the below command  
openssl x509 -fingerprint -in rds-ca-2019-root.pem -noout
```

If you are using the mysql JDBC driver in an application, set the following properties in the application.

```
System.setProperty("javax.net.ssl.trustStore", certs);  
System.setProperty("javax.net.ssl.trustStorePassword", "password");
```

When you start the application, set the following properties.

```
java -Djavax.net.ssl.trustStore=/path_to_truststore/MyTruststore.jks -  
Djavax.net.ssl.trustStorePassword=my_truststore_password com.companyName.MyApplication
```

Example Java code for establishing SSL connections

The following code example shows how to set up the SSL connection that validates the server certificate using JDBC.

```
public class MySQLSSLTest {
```

```
private static final String DB_USER = "username";
private static final String DB_PASSWORD = "password";
// This key store has only the prod root ca.
private static final String KEY_STORE_FILE_PATH = "file-path-to-keystore";
private static final String KEY_STORE_PASS = "keystore-password";

public static void test(String[] args) throws Exception {
    Class.forName("com.mysql.jdbc.Driver");

    System.setProperty("javax.net.ssl.trustStore", KEY_STORE_FILE_PATH);
    System.setProperty("javax.net.ssl.trustStorePassword", KEY_STORE_PASS);

    Properties properties = new Properties();
    properties.setProperty("sslMode", "VERIFY_IDENTITY");
    properties.put("user", DB_USER);
    properties.put("password", DB_PASSWORD);

    Connection connection = null;
    Statement stmt = null;
    ResultSet rs = null;
    try {
        connection =
DriverManager.getConnection("jdbc:mysql://mydatabase.123456789012.us-
east-1.rds.amazonaws.com:3306",properties);
        stmt = connection.createStatement();
        rs=stmt.executeQuery("SELECT 1 from dual");
    } finally {
        if (rs != null) {
            try {
                rs.close();
            } catch (SQLException e) {
            }
        }
        if (stmt != null) {
            try {
                stmt.close();
            } catch (SQLException e) {
            }
        }
        if (connection != null) {
            try {
                connection.close();
            } catch (SQLException e) {
                e.printStackTrace();
            }
        }
    }
    return;
}
```

Important

After you have determined that your database connections use SSL/TLS and have updated your application trust store, you can update your database to use the rds-ca-2019 certificates. For instructions, see step 3 in [Updating your CA certificate by modifying your DB instance \(p. 1636\)](#).

Upgrading the MySQL DB engine

When Amazon RDS supports a new version of a database engine, you can upgrade your DB instances to the new version. There are two kinds of upgrades for MySQL DB instances: major version upgrades and minor version upgrades.

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, you must manually perform major version upgrades of your DB instances. You can initiate a major version upgrade by modifying your DB instance. However, before you perform a major version upgrade, we recommend that you follow the instructions in [Major version upgrades for MySQL \(p. 854\)](#).

In contrast, *minor version upgrades* include only changes that are backward-compatible with existing applications. You can initiate a minor version upgrade manually by modifying your DB instance. Or you can enable the **Auto minor version upgrade** option when creating or modifying a DB instance. Doing so means that your DB instance is automatically upgraded after Amazon RDS tests and approves the new version. For information about performing an upgrade, see [Upgrading a DB instance engine version \(p. 271\)](#).

If your MySQL DB instance is using read replicas, you must upgrade all of the read replicas before upgrading the source instance. If your DB instance is in a Multi-AZ deployment, both the primary and standby replicas are upgraded. Your DB instance will not be available until the upgrade is complete.

Topics

- [Overview of upgrading \(p. 853\)](#)
- [Major version upgrades for MySQL \(p. 854\)](#)
- [Testing an upgrade \(p. 858\)](#)
- [Upgrading a MySQL DB instance \(p. 858\)](#)
- [Automatic minor version upgrades for MySQL \(p. 858\)](#)
- [Using a read replica to reduce downtime when upgrading a MySQL database \(p. 860\)](#)

Overview of upgrading

When you use the AWS Management Console to upgrade a DB instance, it shows the valid upgrade targets for the DB instance. You can also use the following AWS CLI command to identify the valid upgrade targets for a DB instance:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mysql \
--engine-version version-number \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine mysql ^
--engine-version version-number ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For example, to identify the valid upgrade targets for a MySQL version 5.6.43 DB instance, run the following AWS CLI command:

For Linux, macOS, or Unix:

```
aws rds describe-db-engine-versions \
--engine mysql \
--engine-version 5.6.43 \
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

For Windows:

```
aws rds describe-db-engine-versions ^
--engine mysql ^
--engine-version 5.6.43 ^
--query "DBEngineVersions[*].ValidUpgradeTarget[*].{EngineVersion:EngineVersion}" --
output text
```

Amazon RDS takes two DB snapshots during the upgrade process. The first DB snapshot is of the DB instance before any upgrade changes have been made. If the upgrade doesn't work for your databases, you can restore this snapshot to create a DB instance running the old version. The second DB snapshot is taken when the upgrade completes.

Note

Amazon RDS only takes DB snapshots if you have set the backup retention period for your DB instance to a number greater than 0. To change your backup retention period, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

After the upgrade is complete, you can't revert to the previous version of the database engine. If you want to return to the previous version, restore the first DB snapshot taken to create a new DB instance.

You control when to upgrade your DB instance to a new version supported by Amazon RDS. This level of control helps you maintain compatibility with specific database versions and test new versions with your application before deploying in production. When you are ready, you can perform version upgrades at the times that best fit your schedule.

If your DB instance is using read replication, you must upgrade all of the Read Replicas before upgrading the source instance.

If your DB instance is in a Multi-AZ deployment, both the primary and standby DB instances are upgraded. The primary and standby DB instances are upgraded at the same time and you will experience an outage until the upgrade is complete. The time for the outage varies based on your database engine, engine version, and the size of your DB instance.

Major version upgrades for MySQL

Amazon RDS supports the following in-place upgrades for major versions of the MySQL database engine:

- MySQL 5.5 to MySQL 5.6
- MySQL 5.6 to MySQL 5.7
- MySQL 5.7 to MySQL 8.0

Note

You can only create MySQL version 5.7 and 8.0 DB instances with latest-generation and current-generation DB instance classes, in addition to the db.m3 previous-generation DB instance class. In some cases, you want to upgrade a MySQL version 5.6 DB instance running on a previous-generation DB instance class (other than db.m3) to a MySQL version 5.7 DB instance. In

these cases, first modify the DB instance to use a latest-generation or current-generation DB instance class. After you do this, you can then modify the DB instance to use the MySQL version 5.7 database engine. For information on Amazon RDS DB instance classes, see [DB instance classes \(p. 7\)](#).

Topics

- [Overview of MySQL major version upgrades \(p. 855\)](#)
- [Upgrades to MySQL version 5.7 might be slow \(p. 855\)](#)
- [Prechecks for upgrades from MySQL 5.7 to 8.0 \(p. 856\)](#)
- [Rollback after failure to upgrade from MySQL 5.7 to 8.0 \(p. 857\)](#)

Overview of MySQL major version upgrades

Major version upgrades can contain database changes that are not backward-compatible with existing applications. As a result, Amazon RDS doesn't apply major version upgrades automatically; you must manually modify your DB instance. We recommend that you thoroughly test any upgrade before applying it to your production instances.

To perform a major version upgrade for a MySQL version 5.5 DB instance on Amazon RDS to MySQL version 5.6 or later, first perform any available OS updates. After OS updates are complete, upgrade to each major version: 5.5 to 5.6, then 5.6 to 5.7, and then 5.7 to 8.0. MySQL DB instances created before April 24, 2014, show an available OS update until the update has been applied. For more information on OS updates, see [Applying updates for a DB instance \(p. 266\)](#).

During a major version upgrade of MySQL, Amazon RDS runs the MySQL binary `mysql_upgrade` to upgrade tables, if necessary. Also, Amazon RDS empties the `slow_log` and `general_log` tables during a major version upgrade. To preserve log information, save the log contents before the major version upgrade.

MySQL major version upgrades typically complete in about 10 minutes. Some upgrades might take longer because of the DB instance class size or because the instance doesn't follow certain operational guidelines in [Best practices for Amazon RDS \(p. 128\)](#). If you upgrade a DB instance from the Amazon RDS console, the status of the DB instance indicates when the upgrade is complete. If you upgrade using the AWS Command Line Interface (AWS CLI), use the `describe-db-instances` command and check the `Status` value.

Upgrades to MySQL version 5.7 might be slow

MySQL version 5.6.4 introduced a new date and time format for the `datetime`, `time`, and `timestamp` columns that allows fractional components in date and time values. When upgrading a DB instance to MySQL version 5.7, MySQL forces the conversion of all date and time column types to the new format.

Because this conversion rebuilds your tables, it might take a considerable amount of time to complete the DB instance upgrade. The forced conversion occurs for any DB instances that are running a version before MySQL version 5.6.4. It also occurs for any DB instances that were upgraded from a version before MySQL version 5.6.4 to a version other than 5.7.

If your DB instance runs a version before MySQL version 5.6.4, or was upgraded from a version before 5.6.4, we recommend an extra step. In these cases, we recommend that you convert the `datetime`, `time`, and `timestamp` columns in your database before upgrading your DB instance to MySQL version 5.7. This conversion can significantly reduce the amount of time required to upgrade the DB instance to MySQL version 5.7. To upgrade your date and time columns to the new format, issue the `ALTER TABLE <table_name> FORCE`; command for each table that contains date or time columns. Because altering a table locks the table as read-only, we recommend that you perform this update during a maintenance window.

To find all tables in your database that have `datetime`, `time`, or `timestamp` columns and create an `ALTER TABLE <table_name> FORCE;` command for each table, use the following query.

```
SELECT DISTINCT CONCAT('ALTER TABLE `',
    REPLACE(is_tables.TABLE_SCHEMA, '`', ``), `.``,
    REPLACE(is_tables.TABLE_NAME, '`', ``), `` FORCE;')
FROM information_schema.TABLES is_tables
INNER JOIN information_schema.COLUMNS col ON col.TABLE_SCHEMA =
is_tables.TABLE_SCHEMA
    AND col.TABLE_NAME = is_tables.TABLE_NAME
LEFT OUTER JOIN information_schema.INNODB_SYS_TABLES systables ON
    SUBSTRING_INDEX(systables.NAME, '#', 1) =
CONCAT(is_tables.TABLE_SCHEMA,'/',is_tables.TABLE_NAME)
    LEFT OUTER JOIN information_schema.INNODB_SYS_COLUMNS syscolumns ON
        syscolumns.TABLE_ID = systables.TABLE_ID AND syscolumns.NAME = col.COLUMN_NAME
WHERE col.COLUMN_TYPE IN ('time','timestamp','datetime')
    AND is_tables.TABLE_TYPE = 'BASE TABLE'
    AND is_tables.TABLE_SCHEMA NOT IN ('mysql','information_schema','performance_schema')
    AND (is_tables.ENGINE = 'InnoDB' AND syscolumns.MTYPE = 6);
```

Prechecks for upgrades from MySQL 5.7 to 8.0

MySQL 8.0 includes a number of incompatibilities with MySQL 5.7. These incompatibilities can cause problems during an upgrade from MySQL 5.7 to MySQL 8.0. So, some preparation might be required on your database for the upgrade to be successful. The following is a general list of these incompatibilities:

- There must be no tables that use obsolete data types or functions.
- There must be no orphan *.frm files.
- Triggers must not have a missing or empty definer or an invalid creation context.
- There must be no partitioned table that uses a storage engine that does not have native partitioning support.
- There must be no keyword or reserved word violations. Some keywords might be reserved in MySQL 8.0 that were not reserved previously.

For more information, see [Keywords and reserved words](#) in the MySQL documentation.

- There must be no tables in the MySQL 5.7 mysql system database that have the same name as a table used by the MySQL 8.0 data dictionary.
- There must be no obsolete SQL modes defined in your `sql_mode` system variable setting.
- There must be no tables or stored procedures with individual `ENUM` or `SET` column elements that exceed 255 characters or 1020 bytes in length.
- Before upgrading to MySQL 8.0.13 or higher, there must be no table partitions that reside in shared InnoDB tablespaces.
- There must be no queries and stored program definitions from MySQL 8.0.12 or lower that use `ASC` or `DESC` qualifiers for `GROUP BY` clauses.
- Your MySQL 5.7 installation must not use features that are not supported in MySQL 8.0.

For more information, see [Features removed in MySQL 8.0](#) in the MySQL documentation.

- There must be no foreign key constraint names longer than 64 characters.
- For improved Unicode support, consider converting objects that use the `utf8mb3` charset to use the `utf8mb4` charset. The `utf8mb3` character set is deprecated. Also, consider using `utf8mb4` for character set references instead of `utf8`, because currently `utf8` is an alias for the `utf8mb3` charset.

For more information, see [The utf8mb3 character set \(3-byte UTF-8 unicode encoding\)](#) in the MySQL documentation.

When you start an upgrade from MySQL 5.7 to 8.0, Amazon RDS runs prechecks automatically to detect these incompatibilities. For information about upgrading to MySQL 8.0, see [Upgrading MySQL](#) in the MySQL documentation.

These prechecks are mandatory. You can't choose to skip them. The prechecks provide the following benefits:

- They enable you to avoid unplanned downtime during the upgrade.
- If there are incompatibilities, Amazon RDS prevents the upgrade and provides a log for you to learn about them. You can then use the log to prepare your database for the upgrade to MySQL 8.0 by eliminating the incompatibilities. For detailed information about removing incompatibilities, see [Preparing your installation for upgrade](#) in the MySQL documentation and [Upgrading to MySQL 8.0? Here is what you need to know...](#) on the MySQL Server Blog.

The prechecks include some that are included with MySQL and some that were created specifically by the Amazon RDS team. For information about the prechecks provided by MySQL, see [Upgrade checker utility](#).

The prechecks run before the DB instance is stopped for the upgrade, meaning that they don't cause any downtime when they run. If the prechecks find an incompatibility, Amazon RDS automatically cancels the upgrade before the DB instance is stopped. Amazon RDS also generates an event for the incompatibility. For more information about Amazon RDS events, see [Using Amazon RDS event notification \(p. 487\)](#).

Amazon RDS records detailed information about each incompatibility in the log file `PrePatchCompatibility.log`. In most cases, the log entry includes a link to the MySQL documentation for correcting the incompatibility. For more information about viewing log files, see [Viewing and listing database log files \(p. 504\)](#).

Due to the nature of the prechecks, they analyze the objects in your database. This analysis results in resource consumption and increases the time for the upgrade to complete.

Note

Amazon RDS runs prechecks only for an upgrade from MySQL 5.7 to MySQL 8.0. They aren't run for upgrades to releases lower than MySQL 8.0. For example, prechecks aren't run for an upgrade from MySQL 5.6 to MySQL 5.7.

[Rollback after failure to upgrade from MySQL 5.7 to 8.0](#)

When you upgrade a DB instance from MySQL version 5.7 to MySQL version 8.0, the upgrade can fail. In particular, it can fail if the data dictionary contains incompatibilities that weren't captured by the prechecks. In this case, the database fails to start up successfully in the new MySQL 8.0 version. At this point, Amazon RDS rolls back the changes performed for the upgrade. After the rollback, the MySQL DB instance is running MySQL version 5.7. When an upgrade fails and is rolled back, Amazon RDS generates an event with the event ID RDS-EVENT-0188.

Typically, an upgrade fails because there are incompatibilities in the metadata between the databases in your DB instance and the target MySQL version. When an upgrade fails, you can view the details about these incompatibilities in the `upgradeFailure.log` file. Resolve the incompatibilities before attempting to upgrade again.

During an unsuccessful upgrade attempt and rollback, your DB instance is restarted. Any pending parameter changes are applied during the restart and persist after the rollback.

For more information about upgrading to MySQL 8.0, see the following topics in the MySQL documentation:

- [Preparing Your Installation for Upgrade](#)
- [Upgrading to MySQL 8.0? Here is what you need to know...](#)

Note

Currently, automatic rollback after upgrade failure is supported only for MySQL 5.7 to 8.0 major version upgrades.

Testing an upgrade

Before you perform a major version upgrade on your DB instance, thoroughly test your database for compatibility with the new version. In addition, thoroughly test all applications that access the database for compatibility with the new version. We recommend that you use the following procedure.

To test a major version upgrade

1. Review the upgrade documentation for the new version of the database engine to see if there are compatibility issues that might affect your database or applications:
 - [Changes in MySQL 5.6](#)
 - [Changes in MySQL 5.7](#)
 - [Changes in MySQL 8.0](#)
2. If your DB instance is a member of a custom DB parameter group, create a new DB parameter group with your existing settings that is compatible with the new major version. Specify the new DB parameter group when you upgrade your test instance, so your upgrade testing ensures that it works correctly. For more information about creating a DB parameter group, see [Working with DB parameter groups \(p. 228\)](#).
3. Create a DB snapshot of the DB instance to be upgraded. For more information, see [Creating a DB snapshot \(p. 346\)](#).
4. Restore the DB snapshot to create a new test DB instance. For more information, see [Restoring from a DB snapshot \(p. 349\)](#).
5. Modify this new test DB instance to upgrade it to the new version, using one of the methods detailed following. If you created a new parameter group in step 2, specify that parameter group.
6. Evaluate the storage used by the upgraded instance to determine if the upgrade requires additional storage.
7. Run as many of your quality assurance tests against the upgraded DB instance as needed to ensure that your database and application work correctly with the new version. Implement any new tests needed to evaluate the impact of any compatibility issues that you identified in step 1. Test all stored procedures and functions. Direct test versions of your applications to the upgraded DB instance.
8. If all tests pass, then perform the upgrade on your production DB instance. We recommend that you don't allow write operations to the DB instance until you confirm that everything is working correctly.

Upgrading a MySQL DB instance

For information about manually or automatically upgrading a MySQL DB instance, see [Upgrading a DB instance engine version \(p. 271\)](#).

Automatic minor version upgrades for MySQL

If you specify the following settings when creating or modifying a DB instance, you can have your DB instance automatically upgraded.

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.

For more information about these settings, see [Settings for DB instances \(p. 251\)](#).

For some RDS for MySQL major versions in some AWS Regions, one minor version is designated by RDS as the automatic upgrade version. After a minor version has been tested and approved by Amazon RDS, the minor version upgrade occurs automatically during your maintenance window. RDS doesn't automatically set newer released minor versions as the automatic upgrade version. Before RDS designates a newer automatic upgrade version, several criteria are considered, such as the following:

- Known security issues
 - Bugs in the MySQL community version
 - Overall fleet stability since the minor version was released

You can use the following AWS CLI command and script to determine the current automatic minor upgrade target version for a specified MySQL minor version in a specific AWS Region.

```
aws rds describe-db-engine-versions --output=table --engine mysql --engine-version minor-version --region region
```

For example, the following AWS CLI command determines the automatic minor upgrade target for MySQL minor version 5.7.19 in the US East (Ohio) AWS Region (us-east-2).

```
aws rds describe-db-engine-versions --output=table --engine mysql --engine-version 5.7.19  
--region us-east-2
```

Your output is similar to the following.

```
|                                     DescribeDBEngineVersions
+-----+
||                                         DBEngineVersions
+-----+
|| DBEngineDescription                  | MySQL Community Edition
|| DBEngineVersionDescription          | mysql 5.7.19
|| DBParameterGroupFamily             | mysql5.7
|| Engine                            | mysql
|| EngineVersion                     | 5.7.19
|| Status                            | available
|| SupportsGlobalDatabases           | False
|| SupportsLogExportsToCloudwatchLogs| True
|| SupportsParallelQuery             | False
|| SupportsReadReplica               | True
+-----+
||                                         ExportableLogTypes
+-----+
|| audit
|| error
|| general
|| slowquery
|| +-----+
||                                         ValidUpgradeTarget
|| +-----+-----+-----+-----+
|| AutoUpgrade | Description   | Engine    | EngineVersion | IsMajorVersionUpgrade
|| +-----+-----+-----+-----+
|| False       | MySQL 5.7.21  | mysql     | 5.7.21      | False
|| False       | MySQL 5.7.22  | mysql     | 5.7.22      | False
|| False       | MySQL 5.7.23  | mysql     | 5.7.23      | False
|| False       | MySQL 5.7.24  | mysql     | 5.7.24      | False
|| False       | MySQL 5.7.25  | mysql     | 5.7.25      | False
|| True        | MySQL 5.7.26  | mysql     | 5.7.26      | False
```

	False	MySQL 5.7.28	mysql	5.7.28	False	
	False	MySQL 5.7.30	mysql	5.7.30	False	
	False	MySQL 5.7.31	mysql	5.7.31	False	
	False	MySQL 8.0.11	mysql	8.0.11	True	
	False	MySQL 8.0.13	mysql	8.0.13	True	
	False	MySQL 8.0.15	mysql	8.0.15	True	
	False	MySQL 8.0.16	mysql	8.0.16	True	
	False	MySQL 8.0.17	mysql	8.0.17	True	
	False	MySQL 8.0.19	mysql	8.0.19	True	
	False	MySQL 8.0.20	mysql	8.0.20	True	
	False	MySQL 8.0.21	mysql	8.0.21	True	
+-----+-----+-----+-----+-----+-----+						

In this example, the `AutoUpgrade` value is `True` for MySQL version 5.7.26. So, the automatic minor upgrade target is MySQL version 5.7.26, which is highlighted in the output.

A MySQL DB instance is automatically upgraded during your maintenance window if the following criteria are met:

- The **Auto minor version upgrade** setting is enabled.
- The **Backup retention period** setting is greater than 0.
- The DB instance is running a minor DB engine version that is less than the current automatic upgrade minor version.

For more information, see [Automatically upgrading the minor engine version \(p. 273\)](#).

Using a read replica to reduce downtime when upgrading a MySQL database

If your MySQL DB instance is currently in use with a production application, you can use the following procedure to upgrade the database version for your DB instance. This procedure can reduce the amount of downtime for your application.

By using a read replica, you can perform most of the maintenance steps ahead of time and minimize the necessary changes during the actual outage. With this technique, you can test and prepare the new DB instance without making any changes to your existing DB instance.

The following procedure shows an example of upgrading from MySQL version 5.7 to MySQL version 8.0. You can use the same general steps for upgrades to other major versions.

Note

When you are upgrading from MySQL version 5.7 to MySQL version 8.0, complete the prechecks before performing the upgrade. For more information, see [Prechecks for upgrades from MySQL 5.7 to 8.0 \(p. 856\)](#).

To upgrade an MySQL database while a DB instance is in use

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. Create a read replica of your MySQL 5.7 DB instance. This process creates an upgradable copy of your database. Other read replicas of the DB instance might also exist.
 - a. In the console, choose **Databases**, and then choose the DB instance that you want to upgrade.
 - b. For **Actions**, choose **Create read replica**.
 - c. Provide a value for **DB instance identifier** for your read replica and ensure that the **DB instance class** and other settings match your MySQL 5.7 DB instance.

- d. Choose **Create read replica**.
3. (Optional) When the read replica has been created and **Status** shows **Available**, convert the read replica into a Multi-AZ deployment and enable backups.

By default, a read replicas is created as a single-AZ deployment with backups disabled. Because the read replica will ultimately become the production DB instance, it is a best practice to enable configure a Multi-AZ deployment and enable backups now.

- a. In the console, choose **Databases**, and then choose the read replica that you just created.
- b. Choose **Modify**.
- c. For **Multi-AZ deployment**, choose **Create a standby instance**.
- d. For **Backup Retention Period**, choose a positive nonzero value, for example 3 days, and then choose **Continue**.
- e. For **Scheduling of modifications**, choose **Apply immediately**.
- f. Choose **Modify DB instance**.
4. When the read replica **Status** shows **Available**, upgrade the read replica to MySQL 8.0:
 - a. In the console, choose **Databases**, and then choose the read replica that you just created.
 - b. Choose **Modify**.
 - c. For **DB engine version**, choose the MySQL 8.0 version to upgrade to, and then choose **Continue**.
 - d. For **Scheduling of modifications**, choose **Apply immediately**.
 - e. Choose **Modify DB instance** to start the upgrade.
5. When the upgrade is complete and **Status** shows **Available**, verify that the upgraded read replica is up-to-date with the source MySQL 5.7 DB instance. You can do this by connecting to the read replica and issuing the `SHOW SLAVE STATUS` command. If the `Seconds_Behind_Master` field is 0, then replication is up-to-date.
6. (Optional) Create a read replica of your read replica.

If you want the DB instance to have a read replica after it is promoted to a standalone DB instance, you can create the read replica now.

- a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.
- b. For **Actions**, choose **Create read replica**.
- c. Provide a value for **DB instance identifier** for your read replica and ensure that the **DB instance class** and other settings match your MySQL 5.7 DB instance.
- d. Choose **Create read replica**.
7. (Optional) Configure a custom DB parameter group for the read replica.

If you want the DB instance to use a custom parameter group after it is promoted to a standalone DB instance, you can create the DB parameter group now can associate it with the read replica.

- a. Create a custom DB parameter group for MySQL 8.0. For instructions, see [Creating a DB parameter group \(p. 229\)](#).
- b. Modify the parameters that you want to change in the DB parameter group you just created. For instructions, see [Modifying parameters in a DB parameter group \(p. 232\)](#).
- c. In the console, choose **Databases**, and then choose the read replica.
- d. Choose **Modify**.
- e. For **DB parameter group**, choose the MySQL 8.0 DB parameter group you just created, and then choose **Continue**.
- f. For **Scheduling of modifications**, choose **Apply immediately**.
- g. Choose **Modify DB instance** to start the upgrade.
8. Make your MySQL 8.0 read replica a standalone DB instance.

Important

When you promote your MySQL 8.0 read replica to a standalone DB instance, it no longer is a replica of your MySQL 5.7 DB instance. We recommend that you promote your MySQL 8.0 read replica during a maintenance window when your source MySQL 5.7 DB instance is in read-only mode and all write operations are suspended. When the promotion is completed, you can direct your write operations to the upgraded MySQL 8.0 DB instance to ensure that no write operations are lost.

In addition, we recommend that, before promoting your MySQL 8.0 read replica, you perform all necessary data definition language (DDL) operations on your MySQL 8.0 read replica. An example is creating indexes. This approach avoids negative effects on the performance of the MySQL 8.0 read replica after it has been promoted. To promote a read replica, use the following procedure.

- a. In the console, choose **Databases**, and then choose the read replica that you just upgraded.
 - b. For **Actions**, choose **Promote**.
 - c. Choose **Yes** to enable automated backups for the read replica instance. For more information, see [Working with backups \(p. 328\)](#).
 - d. Choose **Continue**.
 - e. Choose **Promote Read Replica**.
9. You now have an upgraded version of your MySQL database. At this point, you can direct your applications to the new MySQL 8.0 DB instance.

Upgrading a MySQL DB snapshot

With Amazon RDS, you can create a storage volume DB snapshot of your MySQL DB instance. When you create a DB snapshot, the snapshot is based on the engine version used by your Amazon RDS instance. In addition to upgrading the DB engine version of your DB instance, you can also upgrade the engine version for your DB snapshots. For example, you can upgrade DB snapshots created from the MySQL 5.1 engine to DB snapshots for the MySQL 5.5 engine. After restoring a DB snapshot upgraded to a new engine version, you should test that the upgrade was successful. To learn how to test a major version upgrade, see [Testing an upgrade \(p. 858\)](#). To learn how to restore a DB snapshot, see [Restoring from a DB snapshot \(p. 349\)](#).

Amazon RDS supports upgrading a MySQL DB snapshot from MySQL 5.1 to MySQL 5.5.

You can upgrade manual DB snapshots, which can be encrypted or not encrypted, from MySQL 5.1 to MySQL 5.5 within the same AWS Region. You can't upgrade automated DB snapshots that are created during the automated backup process.

Console

To upgrade a DB snapshot

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the navigation pane, choose **Snapshots**.
3. For **Actions**, choose **Upgrade snapshot**. The **Upgrade snapshot** page appears.
4. Choose the **New engine version** to upgrade to.
5. Choose **Save changes** to upgrade the snapshot.

During the upgrade process, all snapshot actions are disabled for this DB snapshot. Also, the DB snapshot status changes from **available** to **upgrading**, and then changes to **active** upon completion. If the DB snapshot can't be upgraded because of snapshot corruption issues, the status changes to **unavailable**. You can't recover the snapshot from this state.

Note

If the DB snapshot upgrade fails, the snapshot is rolled back to the original state with the original version.

AWS CLI

To upgrade a DB snapshot to a new database engine version, use the AWS CLI `modify-db-snapshot` command.

Parameters

- `--db-snapshot-identifier` – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see [Working with Amazon Resource Names \(ARNs\) in Amazon RDS \(p. 309\)](#).
- `--engine-version` – The engine version to upgrade the DB snapshot to.

Example

For Linux, macOS, or Unix:

```
aws rds modify-db-snapshot \
```

```
--db-snapshot-identifier <mydbsnapshot> \
--engine-version <new_version>
```

For Windows:

```
aws rds modify-db-snapshot ^
--db-snapshot-identifier <mydbsnapshot> ^
--engine-version <new_version>
```

RDS API

To upgrade a DB snapshot to a new database engine version, call the Amazon RDS API [ModifyDBSnapshot](#) operation.

- **DBSnapshotIdentifier** – The identifier of the DB snapshot to upgrade. The identifier must be a unique Amazon Resource Name (ARN). For more information, see [Working with Amazon Resource Names \(ARNs\) in Amazon RDS \(p. 309\)](#).
- **EngineVersion** – The engine version to upgrade the DB snapshot to.

Importing data into a MySQL DB instance

You can use several different techniques to import data into an Amazon RDS for MySQL DB instance. The best approach depends on the source of the data, the amount of data, and whether the import is done one time or is ongoing. If you are migrating an application along with the data, also consider the amount of downtime that you are willing to experience.

Overview

Find techniques to import data into an Amazon RDS for MySQL DB instance in the following table.

Source	Amount of data	One time or ongoing	Application downtime	Technique	More information
Existing MySQL database on premises or on Amazon EC2	Any	One time	Some	Create a backup of your on-premises database, store it on Amazon S3, and then restore the backup file to a new Amazon RDS DB instance running MySQL.	Restoring a backup into a MySQL DB instance (p. 871)
Any existing database	Any	One time or ongoing	Minimal	Use AWS Database Migration Service to migrate the database with minimal downtime and, for many database DB engines, continue ongoing replication.	What is AWS Database Migration Service in the AWS Database Migration Service User Guide
Existing MySQL DB instance	Any	One time or ongoing	Minimal	Create a read replica for ongoing replication. Promote the read replica for one-time creation of a new DB instance.	Working with read replicas (p. 278)
Existing MySQL or MariaDB database	Small	One time	Some	Copy the data directly to your MySQL DB instance using a command-line utility.	Importing data from a MySQL or MariaDB DB to a MySQL or MariaDB DB instance (p. 879)
Data not stored	Medium	One time	Some	Create flat files and import them using the <code>mysqlimport</code> utility.	Importing data

Source	Amount of data	One time or ongoing	Application downtime	Technique	More information
in an existing database					from any source to a MySQL or MariaDB DB instance (p. 894)
Existing MySQL or MariaDB database on premises or on Amazon EC2	Any	Ongoing	Minimal	Configure replication with an existing MySQL database as the replication source.	Replication with a MySQL or MariaDB instance running external to Amazon RDS (p. 914) or Importing data to an Amazon RDS MySQL or MariaDB DB instance with reduced downtime (p. 881)

Note

The 'mysql' system database contains authentication and authorization information required to log in to your DB instance and access your data. Dropping, altering, renaming, or truncating tables, data, or other contents of the 'mysql' database in your DB instance can result in error and might render the DB instance and your data inaccessible. If this occurs, you can restore the DB instance from a snapshot using the AWS CLI `restore-db-instance-from-db-snapshot` command. You can recover the DB instance using the AWS CLI `restore-db-instance-to-point-in-time` command.

Importing data considerations

Following, you can find additional technical information related to loading data into MySQL. This information is intended for advanced users who are familiar with the MySQL server architecture. All comments related to `LOAD DATA LOCAL INFILE` also apply to `mysqldump`.

Binary log

Data loads incur a performance penalty and require additional free disk space (up to four times more) when binary logging is enabled versus loading the same data with binary logging turned off. The severity of the performance penalty and the amount of free disk space required is directly proportional to the size of the transactions used to load the data.

Transaction size

Transaction size plays an important role in MySQL data loads. It has a major influence on resource consumption, disk space utilization, resume process, time to recover, and input format (flat files or SQL). This section describes how transaction size affects binary logging and makes the case for disabling binary logging during large data loads. As noted earlier, binary logging is enabled and disabled by setting the Amazon RDS automated backup retention period. Non-zero values enable binary logging, and zero disables it. We also describe the impact of large transactions on InnoDB and why it's important to keep transaction sizes small.

Small transactions

For small transactions, binary logging doubles the number of disk writes required to load the data. This effect can severely degrade performance for other database sessions and increase the time required to load the data. The degradation experienced depends in part upon the upload rate, other database activity taking place during the load, and the capacity of your Amazon RDS DB instance.

The binary logs also consume disk space roughly equal to the amount of data loaded until they are backed up and removed. Fortunately, Amazon RDS minimizes this by backing up and removing binary logs on a frequent basis.

Large transactions

Large transactions incur a 3X penalty for IOPS and disk consumption with binary logging enabled. This is due to the binary log cache spilling to disk, consuming disk space and incurring additional IO for each write. The cache cannot be written to the binlog until the transaction commits or rolls back, so it consumes disk space in proportion to the amount of data loaded. When the transaction commits, the cache must be copied to the binlog, creating a third copy of the data on disk.

Because of this, there must be at least three times as much free disk space available to load the data compared to loading with binary logging disabled. For example, 10 GiB of data loaded as a single transaction consumes at least 30 GiB disk space during the load. It consumes 10 GiB for the table + 10 GiB for the binary log cache + 10 GiB for the binary log itself. The cache file remains on disk until the session that created it terminates or the session fills its binary log cache again during another transaction. The binary log must remain on disk until backed up, so it might be some time before the extra 20 GiB is freed.

If the data was loaded using LOAD DATA LOCAL INFILE, yet another copy of the data is created if the database has to be recovered from a backup made before the load. During recovery, MySQL extracts the data from the binary log into a flat file. MySQL then runs LOAD DATA LOCAL INFILE, just as in the original transaction. However, this time the input file is local to the database server. Continuing with the example preceding, recovery fails unless there is at least 40 GiB free disk space available.

Disable binary logging

Whenever possible, disable binary logging during large data loads to avoid the resource overhead and addition disk space requirements. In Amazon RDS, disabling binary logging is as simple as setting the backup retention period to zero. If you do this, we recommend that you take a DB snapshot of the database instance immediately before the load. By doing this, you can quickly and easily undo changes made during loading if you need to.

After the load, set the backup retention period back to an appropriate (no zero) value.

You can't set the backup retention period to zero if the DB instance is a source DB instance for read replicas.

InnoDB

The information in this section provides a strong argument for keeping transaction sizes small when using InnoDB.

Undo

InnoDB generates undo to support features such as transaction rollback and MVCC. Undo is stored in the InnoDB system tablespace (usually `ibdata1`) and is retained until removed by the purge thread. The purge thread cannot advance beyond the undo of the oldest active transaction, so it is effectively blocked until the transaction commits or completes a rollback. If the database is processing other transactions during the load, their undo also accumulates in the system tablespace and cannot be removed even if they commit and no other transaction needs the undo for MVCC. In this situation, all transactions (including read-only transactions) that access any of the rows changed by any transaction (not just the load transaction) slow down. The slowdown occurs because transactions scan through undo that could have been purged if not for the long-running load transaction.

Undo is stored in the system tablespace, and the system tablespace never shrinks in size. Thus, large data load transactions can cause the system tablespace to become quite large, consuming disk space that you can't reclaim without recreating the database from scratch.

Rollback

InnoDB is optimized for commits. Rolling back a large transaction can take a very, very long time. In some cases, it might be faster to perform a point-in-time recovery or restore a DB snapshot.

Input data format

MySQL can accept incoming data in one of two forms: flat files and SQL. This section points out some key advantages and disadvantages of each.

Flat files

Loading flat files with `LOAD DATA LOCAL INFILE` can be the fastest and least costly method of loading data as long as transactions are kept relatively small. Compared to loading the same data with SQL, flat files usually require less network traffic, lowering transmission costs and load much faster due to the reduced overhead in the database.

One big transaction

`LOAD DATA LOCAL INFILE` loads the entire flat file as one transaction. This isn't necessarily a bad thing. If the size of the individual files can be kept small, this has a number of advantages:

- Resume capability – Keeping track of which files have been loaded is easy. If a problem arises during the load, you can pick up where you left off with little effort. Some data might have to be retransmitted to Amazon RDS, but with small files, the amount retransmitted is minimal.
- Load data in parallel – If you've got IOPS and network bandwidth to spare with a single file load, loading in parallel might save time.
- Throttle the load rate – Data load having a negative impact on other processes? Throttle the load by increasing the interval between files.

Be careful

The advantages of LOAD DATA LOCAL INFILE diminish rapidly as transaction size increases. If breaking up a large set of data into smaller ones isn't an option, SQL might be the better choice.

SQL

SQL has one main advantage over flat files: it's easy to keep transaction sizes small. However, SQL can take significantly longer to load than flat files and it can be difficult to determine where to resume the load after a failure. For example, mysqldump files are not restartable. If a failure occurs while loading a mysqldump file, the file requires modification or replacement before the load can resume. The alternative is to restore to the point in time before the load and replay the file after the cause of the failure has been corrected.

Take checkpoints using Amazon RDS snapshots

If you have a load that's going to take several hours or even days, loading without binary logging isn't a very attractive prospect unless you can take periodic checkpoints. This is where the Amazon RDS DB snapshot feature comes in very handy. A DB snapshot creates a point-in-time consistent copy of your database instance which can be used to restore the database to that point in time after a crash or other mishap.

To create a checkpoint, simply take a DB snapshot. Any previous DB snapshots taken for checkpoints can be removed without affecting durability or restore time.

Snapshots are fast too, so frequent checkpointing doesn't add significantly to load time.

Decreasing load time

Here are some additional tips to reduce load times:

- Create all secondary indexes before loading. This is counter-intuitive for those familiar with other databases. Adding or modifying a secondary index causes MySQL to create a new table with the index changes, copy the data from the existing table to the new table, and drop the original table.
- Load data in PK order. This is particularly helpful for InnoDB tables, where load times can be reduced by 75–80 percent and data file size cut in half.
- Disable foreign key constraints `foreign_key_checks=0`. For flat files loaded with LOAD DATA LOCAL INFILE, this is required in many cases. For any load, disabling FK checks provides significant performance gains. Just be sure to enable the constraints and verify the data after the load.
- Load in parallel unless already near a resource limit. Use partitioned tables when appropriate.
- Use multi-value inserts when loading with SQL to minimize overhead when running statements. When using mysqldump, this is done automatically.
- Reduce InnoDB log IO `innodb_flush_log_at_trx_commit=0`
- If you are loading data into a DB instance that does not have read replicas, set the `sync_binlog` parameter to 0 while loading data. When data loading is complete, set the `sync_binlog` parameter back to 1.
- Load data before converting the DB instance to a Multi-AZ deployment. However, if the DB instance already uses a Multi-AZ deployment, switching to a Single-AZ deployment for data loading is not recommended, because doing so only provides marginal improvements.

Note

Using `innodb_flush_log_at_trx_commit=0` causes InnoDB to flush its logs every second instead of at each commit. This provides a significant speed advantage, but can lead to data loss during a crash. Use with caution.

Restoring a backup into a MySQL DB instance

Amazon RDS supports importing MySQL databases by using backup files. You can create a backup of your database, store it on Amazon S3, and then restore the backup file onto a new Amazon RDS DB instance running MySQL.

The scenario described in this section restores a backup of an on-premises database. You can use this technique for databases in other locations, such as Amazon EC2 or non-AWS cloud services, as long as the database is accessible.

You can find the supported scenario in the following diagram.

Importing backup files from Amazon S3 is supported for MySQL version 5.6, 5.7, and 8.0. Importing backup files from Amazon S3 is available in all AWS Regions.

We recommend that you import your database to Amazon RDS by using backup files if your on-premises database can be offline while the backup file is created, copied, and restored. If your database can't be offline, you can use binary log (binlog) replication to update your database after you have migrated to Amazon RDS through Amazon S3 as explained in this topic. For more information, see [Replication with a MySQL or MariaDB instance running external to Amazon RDS \(p. 914\)](#). You can also use the AWS Database Migration Service to migrate your database to Amazon RDS. For more information, see [What is AWS Database Migration Service?](#)

Limitations and recommendations for importing backup files from Amazon S3 to Amazon RDS

The following are some limitations and recommendations for importing backup files from Amazon S3:

- You can only import your data to a new DB instance, not an existing DB instance.
- You must use Percona XtraBackup to create the backup of your on-premises database.
- You can't migrate from a source database that has tables defined outside of the default MySQL data directory.
- You must import your data to the default minor version of your MySQL major version in your AWS Region. For example, if your major version is MySQL 5.6, and the default minor version for your AWS Region is 5.6.44, then you must import your data into a MySQL version 5.6.44 DB instance. You can

upgrade your DB instance after importing. For information about determining the default minor version, see [MySQL on Amazon RDS versions \(p. 828\)](#).

- Backward migration is not supported for both major versions and minor versions. For example, you can't migrate from version 5.7 to version 5.6, and you can't migrate from version 5.6.39 to version 5.6.37.
- You can't import a MySQL 5.5 database.
- You can't import an on-premises MySQL database from one major version to another. For example, you can't import a MySQL 5.6 database to an Amazon RDS MySQL 5.7 or 8.0 database. Similarly, you can't import a MySQL 5.7 database to an RDS for MySQL 8.0 database. You can upgrade your DB instance after you complete the import.
- You can't restore from an encrypted source database, but you can restore to an encrypted Amazon RDS DB instance.
- You can't restore from an encrypted backup in the Amazon S3 bucket.
- You can't restore from an Amazon S3 bucket in a different AWS Region than your Amazon RDS DB instance.
- Importing from Amazon S3 is not supported on the db.t2.micro DB instance class. However, you can restore to a different DB instance class, and change the DB instance class later. For more information about instance classes, see [Hardware specifications for DB instance classes \(p. 33\)](#).
- Amazon S3 limits the size of a file uploaded to an Amazon S3 bucket to 5 TB. If a backup file exceeds 5 TB, then you must split the backup file into smaller files.
- When you restore the database, the backup is copied and then extracted on your DB instance. Therefore, provision storage space for your DB instance that is equal to or greater than the sum of the backup size, plus the original database's size on disk.
- Amazon RDS limits the number of files uploaded to an Amazon S3 bucket to 1 million. If the backup data for your database, including all full and incremental backups, exceeds 1 million files, use a Gzip (.gz), tar (.tar.gz), or Percona xbstream (.xbstream) file to store full and incremental backup files in the Amazon S3 bucket. Percona XtraBackup 8.0 only supports Percona xbstream for compression.
- User accounts are not imported automatically. Save your user accounts from your source database and add them to your new DB instance later.
- Functions are not imported automatically. Save your functions from your source database and add them to your new DB instance later.
- Stored procedures are not imported automatically. Save your stored procedures from your source database and add them to your new DB instance later.
- Time zone information is not imported automatically. Record the time zone information for your source database, and set the time zone of your new DB instance later. For more information, see [Local time zone for MySQL DB instances \(p. 838\)](#).
- The `innodb_data_file_path` parameter must be configured with only one data file that uses the default data file name "ibdata1:12M:autoextend". Databases with two data files, or with a data file with a different name, can't be migrated using this method.

The following are examples of file names that are not allowed:

"`innodb_data_file_path=ibdata1:50M; ibdata2:50M:autoextend`" and
"`innodb_data_file_path=ibdata01:50M:autoextend`".

- The maximum size of the restored database is the maximum database size supported minus the size of the backup. So, if the maximum database size supported is 64 TiB, and the size of the backup is 30 TiB, then the maximum size of the restored database is 34 TiB, as in the following example:

$64 \text{ TiB} - 30 \text{ TiB} = 34 \text{ TiB}$

For information about the maximum database size supported by Amazon RDS for MySQL, see [General Purpose SSD storage \(p. 40\)](#) and [Provisioned IOPS SSD storage \(p. 42\)](#).

Overview of setting up to import backup files from Amazon S3 to Amazon RDS

These are the components you need to set up to import backup files from Amazon S3 to Amazon RDS:

- An Amazon S3 bucket to store your backup files.
- A backup of your on-premises database created by Percona XtraBackup.
- An AWS Identity and Access Management (IAM) role to allow Amazon RDS to access the bucket.

If you already have an Amazon S3 bucket, you can use that. If you don't have an Amazon S3 bucket, you can create a new one. If you want to create a new bucket, see [Creating a bucket](#).

Use the Percona XtraBackup tool to create your backup. For more information, see [Creating your database backup \(p. 873\)](#).

If you already have an IAM role, you can use that. If you don't have an IAM role, you can create a new one manually. Alternatively, you can choose to have a new IAM role created for you in your account by the wizard when you restore the database by using the AWS Management Console. If you want to create a new IAM role manually, or attach trust and permissions policies to an existing IAM role, see [Creating an IAM role manually \(p. 875\)](#). If you want to have a new IAM role created for you, follow the procedure in [Console \(p. 876\)](#).

Creating your database backup

Use the Percona XtraBackup software to create your backup. You can install Percona XtraBackup from [Download Percona XtraBackup](#).

Note

For MySQL 8.0 migration, you must use Percona XtraBackup 8.0. Percona XtraBackup 8.0.12 and higher versions support migration of all versions of MySQL. If you are migrating to RDS for MySQL 8.0.20 or higher, you must use Percona XtraBackup 8.0.12 or higher.

For MySQL 5.7 migrations, you can also use Percona XtraBackup 2.4. For migrations of earlier MySQL versions, you can also use Percona XtraBackup 2.3 or 2.4.

You can create a full backup of your MySQL database files using Percona XtraBackup. Alternatively, if you already use Percona XtraBackup to back up your MySQL database files, you can upload your existing full and incremental backup directories and files.

For more information about backing up your database with Percona XtraBackup, see [Percona XtraBackup - documentation](#) and [The xtrabackup binary](#) on the Percona website.

Creating a full backup with Percona XtraBackup

To create a full backup of your MySQL database files that can be restored from Amazon S3, use the Percona XtraBackup utility (`xtrabackup`) to back up your database.

For example, the following command creates a backup of a MySQL database and stores the files in the folder `/on-premises/s3-restore/backup` folder.

```
xtrabackup --backup --user=<myuser> --password=<password> --target-dir=</on-premises/s3-restore/backup>
```

If you want to compress your backup into a single file (which can be split later, if needed), you can save your backup in one of the following formats:

- Gzip (.gz)
- tar (.tar)
- Percona xbstream (.xbstream)

Note

Percona XtraBackup 8.0 only supports Percona xbstream for compression.

The following command creates a backup of your MySQL database split into multiple Gzip files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar \  
--target-dir=</on-premises/s3-restore/backup> | gzip - | split -d --bytes=500MB \  
- </on-premises/s3-restore/backup/backup>.tar.gz
```

The following command creates a backup of your MySQL database split into multiple tar files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=tar \  
--target-dir=</on-premises/s3-restore/backup> | split -d --bytes=500MB \  
- </on-premises/s3-restore/backup/backup>.tar
```

The following command creates a backup of your MySQL database split into multiple xbstream files.

```
xtrabackup --backup --user=<myuser> --password=<password> --stream=xbstream \  
--target-dir=</on-premises/s3-restore/backup> | split -d --bytes=500MB \  
- </on-premises/s3-restore/backup/backup>.xbstream
```

Using incremental backups with Percona XtraBackup

If you already use Percona XtraBackup to perform full and incremental backups of your MySQL database files, you don't need to create a full backup and upload the backup files to Amazon S3. Instead, you can save a significant amount of time by copying your existing backup directories and files to your Amazon S3 bucket. For more information about creating incremental backups using Percona XtraBackup, see [Incremental backup](#).

When copying your existing full and incremental backup files to an Amazon S3 bucket, you must recursively copy the contents of the base directory. Those contents include the full backup and also all incremental backup directories and files. This copy must preserve the directory structure in the Amazon S3 bucket. Amazon RDS iterates through all files and directories. Amazon RDS uses the `xtrabackup-checkpoints` file that is included with each incremental backup to identify the base directory, and to order incremental backups by log sequence number (LSN) range.

Backup considerations for Percona XtraBackup

Amazon RDS consumes your backup files based on the file name. Name your backup files with the appropriate file extension based on the file format—for example, `.xbstream` for files stored using the Percona xbstream format.

Amazon RDS consumes your backup files in alphabetical order and also in natural number order. Use the `split` option when you issue the `xtrabackup` command to ensure that your backup files are written and named in the proper order.

Amazon RDS doesn't support partial backups created using Percona XtraBackup. You can't use the following options to create a partial backup when you back up the source files for your database: `--tables`, `--tables-exclude`, `--tables-file`, `--databases`, `--databases-exclude`, or `--databases-file`.

Amazon RDS supports incremental backups created using Percona XtraBackup. For more information about creating incremental backups using Percona XtraBackup, see [Incremental backup](#).

Creating an IAM role manually

If you don't have an IAM role, you can create a new one manually. Alternatively, you can choose to have a new IAM role created for you by the wizard when you restore the database by using the AWS Management Console. If you want to have a new IAM role created for you, follow the procedure in [Console \(p. 876\)](#).

To manually create a new IAM role for importing your database from Amazon S3, create a role to delegate permissions from Amazon RDS to your Amazon S3 bucket. When you create an IAM role, you attach trust and permissions policies. To import your backup files from Amazon S3, use trust and permissions policies similar to the examples following. For more information about creating the role, see [Creating a role to delegate permissions to an AWS service](#).

Alternatively, you can choose to have a new IAM role created for you by the wizard when you restore the database by using the AWS Management Console. If you want to have a new IAM role created for you, follow the procedure in [Console \(p. 876\)](#)

The trust and permissions policies require that you provide an Amazon Resource Name (ARN). For more information about ARN formatting, see [Amazon Resource Names \(ARNs\) and AWS service namespaces](#).

Example Trust policy for importing from Amazon S3

```
{  
    "Version": "2012-10-17",  
    "Statement":  
    [ {  
        "Effect": "Allow",  
        "Principal": {"Service": "rds.amazonaws.com"},  
        "Action": "sts:AssumeRole"  
    } ]  
}
```

Example Permissions policy for importing from Amazon S3 — IAM user permissions

```
{  
    "Version": "2012-10-17",  
    "Statement":  
    [ {  
        "Sid": "AllowS3AccessRole",  
        "Effect": "Allow",  
        "Action": "iam:PassRole",  
        "Resource": "arn:aws:iam::IAM User ID:role/S3Access"  
    } ]  
}
```

Example Permissions policy for importing from Amazon S3 — role permissions

```
{  
    "Version": "2012-10-17",  
    "Statement":  
    [ {  
        "Effect": "Allow",  
        "Action": "s3:PutObject",  
        "Resource": "arn:aws:s3:::mybucket/*"  
    } ]  
}
```

```
"Action":  
  [  
    "s3>ListBucket",  
    "s3:GetBucketLocation"  
  ],  
  "Resource": "arn:aws:s3:::bucket_name"  
},  
{  
  "Effect": "Allow",  
  "Action":  
    [  
      "s3.GetObject"  
    ],  
  "Resource": "arn:aws:s3:::bucket_name/prefix*"  
}  
]  
}
```

Note

If you include a file name prefix, include the asterisk (*) after the prefix. If you don't want to specify a prefix, specify only an asterisk.

Importing data from Amazon S3 to a new MySQL DB instance

You can import data from Amazon S3 to a new MySQL DB instance using the AWS Management Console, AWS CLI, or RDS API.

Console

To import data from Amazon S3 to a new MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the top right corner of the Amazon RDS console, choose the AWS Region in which to create your DB instance. Choose the same AWS Region as the Amazon S3 bucket that contains your database backup.
3. In the navigation pane, choose **Databases**.
4. Choose **Restore from S3**.

The **Create database by restoring from S3** page appears.

Create database by restoring from S3

S3 destination

Write audit logs to S3

Enter a destination in Amazon S3 where your audit logs will be stored. Amazon S3 is object storage build to store and retrieve any amount of data from anywhere

S3 bucket

test-eu1-bucket

S3 prefix (optional) [Info](#)

Engine options

Engine type [Info](#)

Amazon Aurora

Edition

MySQL Community

Source engine version [Info](#)

5.6

Version [Info](#)

MySQL 5.6.44

Known Issues/Limitations

Review the [Known Issues/Limitations](#) to learn about potential compatibility issues with specific database versions.

IAM role

IAM role

Choose or create an IAM role to grant write access to your S3 bucket.

[Choose an option](#)

Settings

877

DB instance identifier [Info](#)

Type a name for your DB instance. The name must be unique across all DB instances owned by your AWS account in the current AWS Region.

database-1

5. Under **S3 destination**:

- a. Choose the **S3 bucket** where to write audit logs.
- b. (Optional) For **S3 folder path prefix**, enter a file path prefix for the files stored in your Amazon S3 bucket.

If you don't specify a prefix, then RDS creates your DB instance using all of the files and folders in the root folder of the S3 bucket. If you do specify a prefix, then RDS creates your DB instance using the files and folders in the S3 bucket where the path for the file begins with the specified prefix.

For example, suppose that you store your backup files on S3 in a subfolder named backups, and you have multiple sets of backup files, each in its own directory (gzip_backup1, gzip_backup2, and so on). In this case, you specify a prefix of backups/gzip_backup1 to restore from the files in the gzip_backup1 folder.

6. Under **Engine options**:

- a. For **Engine type**, choose **MySQL**.
 - b. For **Source engine version**, choose the MySQL major version of your source database.
 - c. For **Version**, choose the MySQL engine version for your restored DB instance.
7. For **IAM role**, you can choose an existing IAM role.
8. (Optional) You can also have a new IAM role created for you by choosing **Create a new role** and entering the **IAM role name**.
9. Specify your DB instance information. For information about each setting, see [Settings for DB instances \(p. 145\)](#).

Note

Be sure to allocate enough memory for your new DB instance so that the restore operation can succeed.

You can also choose **Enable storage autoscaling** to allow for future growth automatically.

10. Choose additional settings as needed.

11. Choose **Create database**.

AWS CLI

To import data from Amazon S3 to a new MySQL DB instance by using the AWS CLI, call the [restore-db-instance-from-s3](#) command with the following parameters. For information about each setting, see [Settings for DB instances \(p. 145\)](#).

Note

Be sure to allocate enough memory for your new DB instance so that the restore operation can succeed.

You can also use the `--max-allocated-storage` parameter to enable storage autoscaling and allow for future growth automatically.

- `--allocated-storage`
- `--db-instance-identifier`
- `--db-instance-class`
- `--engine`
- `--master-username`
- `--master-user-password`
- `--s3-bucket-name`
- `--s3-ingestion-role-arn`

- `--s3-prefix`
- `--source-engine`
- `--source-engine-version`

Example

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-s3 \
    --allocated-storage 250 \
    --db-instance-identifier myidentifier \
    --db-instance-class db.m5.large \
    --engine mysql \
    --master-username admin \
    --master-user-password mypassword \
    --s3-bucket-name mybucket \
    --s3-ingestion-role-arn arn:aws:iam::account-number:role/rolename \
    --s3-prefix bucketprefix \
    --source-engine mysql \
    --source-engine-version 5.6.44 \
    --max-allocated-storage 1000
```

For Windows:

```
aws rds restore-db-instance-from-s3 ^
    --allocated-storage 250 ^
    --db-instance-identifier myidentifier ^
    --db-instance-class db.m5.large ^
    --engine mysql ^
    --master-username admin ^
    --master-user-password mypassword ^
    --s3-bucket-name mybucket ^
    --s3-ingestion-role-arn arn:aws:iam::account-number:role/rolename ^
    --s3-prefix bucketprefix ^
    --source-engine mysql ^
    --source-engine-version 5.6.44 ^
    --max-allocated-storage 1000
```

RDS API

To import data from Amazon S3 to a new MySQL DB instance by using the Amazon RDS API, call the [RestoreDBInstanceFromS3](#) operation.

Importing data from a MySQL or MariaDB DB to a MySQL or MariaDB DB instance

If your scenario supports it, it is easier to move data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see [Restoring a backup into a MySQL DB instance \(p. 871\)](#).

You can also import data from an existing MySQL or MariaDB database to a MySQL or MariaDB DB instance. You do so by copying the database with [mysqldump](#) and piping it directly into the MySQL or MariaDB DB instance. The [mysqldump](#) command-line utility is commonly used to make backups and transfer data from one MySQL or MariaDB server to another. It is included with MySQL and MariaDB client software.

A typical [mysqldump](#) command to move data from an external database to an Amazon RDS DB instance looks similar to the following:

```
mysqldump -u local_user \
    --databases database_name \
    --single-transaction \
    --compress \
    --order-by-primary \
    -plocal_password | mysql -u RDS_user \
        --port=port_number \
        --host=host_name \
        -pRDS_password
```

Important

Make sure not to leave a space between the `-p` option and the entered password.

Note

- Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The `mysqldump` utility excludes these schemas by default.
- If you need to migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the [pt-show-grants](#) utility.

The parameters used are as follows:

- `-u local_user` – Use to specify a user name. In the first usage of this parameter, you specify the name of a user account on the local MySQL or MariaDB database identified by the `--databases` parameter.
- `--databases database_name` – Use to specify the name of the database on the local MySQL or MariaDB instance that you want to import into Amazon RDS.
- `--single-transaction` – Use to ensure that all of the data loaded from the local database is consistent with a single point in time. If there are other processes changing the data while `mysqldump` is reading it, using this option helps maintain data integrity.
- `--compress` – Use to reduce network bandwidth consumption by compressing the data from the local database before sending it to Amazon RDS.
- `--order-by-primary` – Use to reduce load time by sorting each table's data by its primary key.
- `-plocal_password` – Use to specify a password. In the first usage of this parameter, you specify the password for the user account identified by the first `-u` parameter.
- `-u RDS_user` – Use to specify a user name. In the second usage of this parameter, you specify the name of a user account on the default database for the MySQL or MariaDB DB instance identified by the `--host` parameter.
- `--port port_number` – Use to specify the port for your MySQL or MariaDB DB instance. By default, this is 3306 unless you changed the value when creating the instance.
- `--host host_name` – Use to specify the DNS name from the Amazon RDS DB instance endpoint, for example, `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.
- `-pRDS_password` – Use to specify a password. In the second usage of this parameter, you specify the password for the user account identified by the second `-u` parameter.

You must create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, then exclude them when you run `mysqldump` by including the following parameters with your `mysqldump` command: `--routines=0 --triggers=0 --events=0`.

The following example copies the `world` sample database on the local host to a MySQL DB instance.

For Linux, macOS, or Unix:

```
sudo mysqldump -u localuser \
--databases world \
--single-transaction \
--compress \
--order-by-primary \
-plocalpassword | mysql -u rdsuser \
--port=3306 \
--host=myinstance.123456789012.us-east-1.rds.amazonaws.com \
-prdspassword
```

For Windows, the following command needs to be run in a command prompt that has been opened by right-clicking **Command Prompt** on the Windows programs menu and choosing **Run as administrator**:

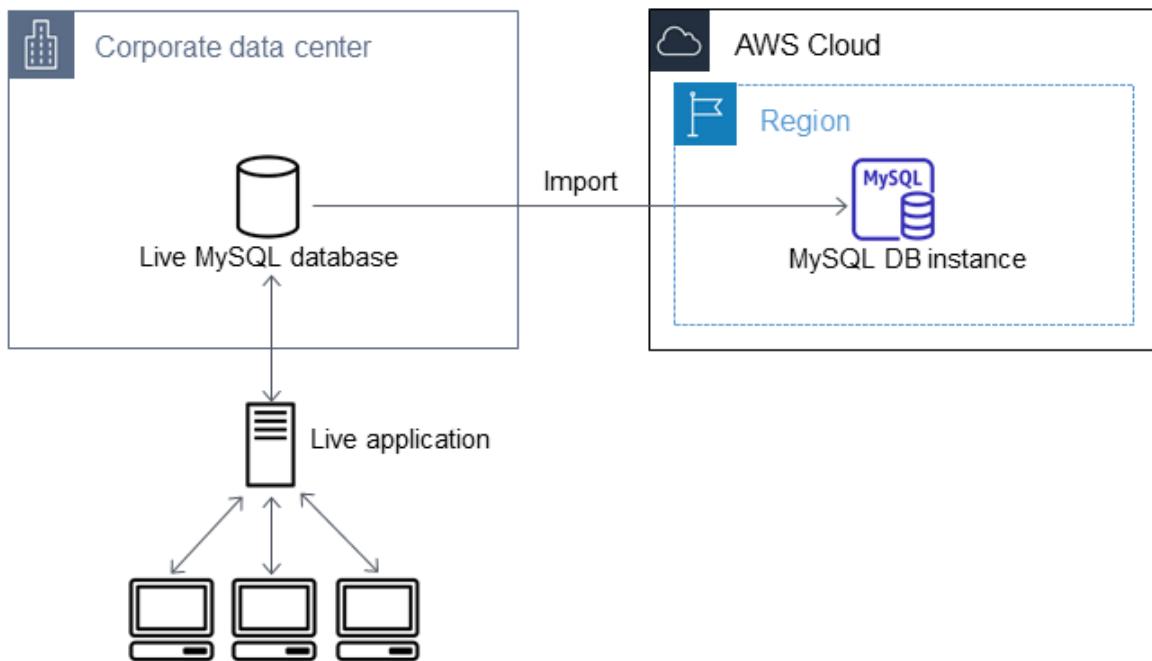

```
mysqldump -u localuser ^
--databases world ^
--single-transaction ^
--compress ^
--order-by-primary ^
-plocalpassword | mysql -u rdsuser ^
--port=3306 ^
--host=myinstance.123456789012.us-east-1.rds.amazonaws.com ^
-prdspassword
```

Importing data to an Amazon RDS MySQL or MariaDB DB instance with reduced downtime

If your scenario supports it, it is easier to move data in and out of Amazon RDS by using backup files and Amazon S3. For more information, see [Restoring a backup into a MySQL DB instance \(p. 871\)](#).

In some cases, you might need to import data from an external MySQL or MariaDB database that supports a live application to a MySQL or MariaDB DB instance. In these cases, you can use the following procedure to minimize the impact on application availability. This procedure can also help if you are working with a very large database. Here, the procedure helps because you can reduce the cost of the import by reducing the amount of data that is passed across the network to AWS.

In this procedure, you transfer a copy of your database data to an Amazon EC2 instance and import the data into a new Amazon RDS DB instance. You then use replication to bring the Amazon RDS DB instance up-to-date with your live external instance, before redirecting your application to the Amazon RDS DB instance. You configure MariaDB replication based on global transaction identifiers (GTIDs) if the external instance is MariaDB 10.0.2 or greater and the target instance is RDS for MariaDB; otherwise, you configure replication based on binary log coordinates. We recommend GTID-based replication if your external database supports it due to its enhanced crash-safety features. For more information, see [Global transaction ID](#) in the MariaDB documentation.

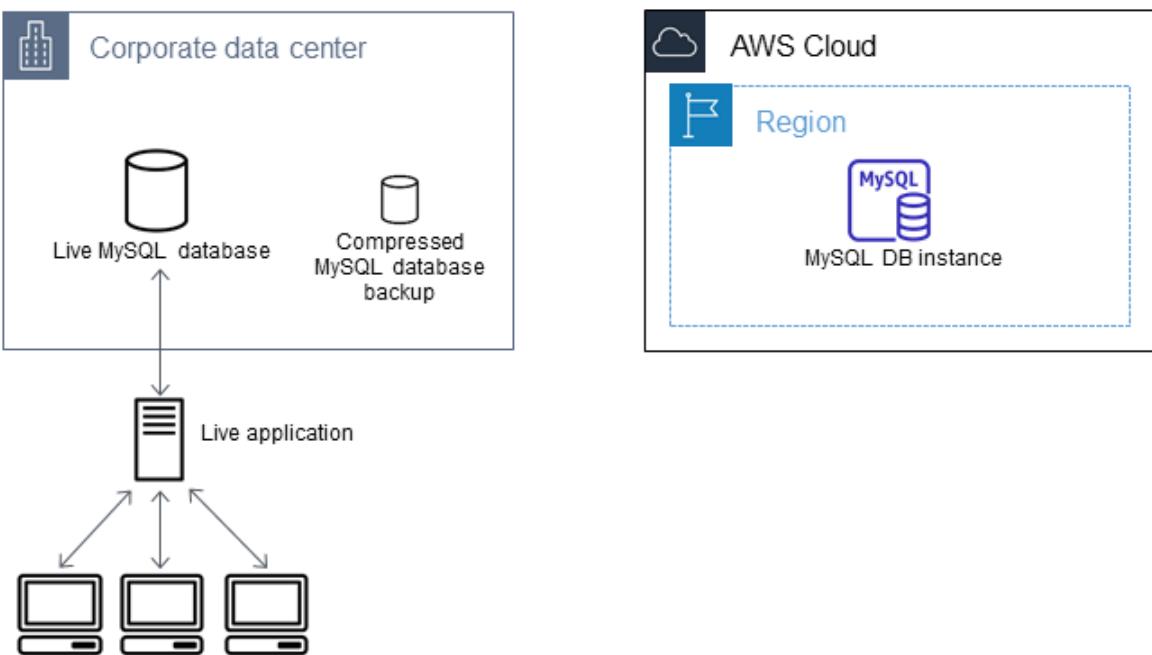

Note

We don't recommend that you use this procedure with source MySQL databases from MySQL versions earlier than version 5.1, due to potential replication issues. For more information, see [Replication compatibility between MySQL versions](#) in the MySQL documentation.

Create a copy of your existing database

The first step in the process of migrating a large amount of data to an Amazon RDS MySQL or MariaDB DB instance with minimal downtime is to create a copy of the source data.

You can use the `mysqldump` utility to create a database backup in either SQL or delimited-text format. You should do a test run with each format in a nonproduction environment to see which method minimizes the amount of time that `mysqldump` runs.

You should also weigh `mysqldump` performance against the benefit offered by using the delimited-text format for loading. A backup using delimited-text format creates a tab-separated text file for each table being dumped. You can load these files in parallel using the `LOAD DATA LOCAL INFILE` command to reduce the amount of time required to import your database. For more information about choosing a `mysqldump` format and then loading the data, see [Using mysqldump for backups](#) in the MySQL documentation.

Before you start the backup operation, you must set the replication options on the MySQL or MariaDB database that you are copying to Amazon RDS. The replication options include enabling binary logging and setting a unique server ID. Setting these options causes your server to start logging database transactions and prepares it to be a source replication instance later in this process.

Note

- Use the `--single-transaction` option with `mysqldump` because it dumps a consistent state of the database. To ensure a valid dump file, don't run data definition language (DDL) statements while `mysqldump` is running. You can schedule a maintenance window for these operations.
- Exclude the following schemas from the dump file: `sys`, `performance_schema`, and `information_schema`. The `mysqldump` utility excludes these schemas by default.
- If you need to migrate users and privileges, consider using a tool that generates the data control language (DCL) for recreating them, such as the [pt-show-grants](#) utility.

To set replication options

1. Edit the `my.cnf` file (this file is usually under `/etc`).

```
sudo vi /etc/my.cnf
```

Add the `log_bin` and `server_id` options to the `[mysqld]` section. The `log_bin` option provides a file name identifier for binary log files. The `server_id` option provides a unique identifier for the server in source-replica relationships.

The following example shows the updated `[mysqld]` section of a `my.cnf` file:

```
[mysqld]
log-bin=mysql-bin
server-id=1
```

For more information, see [the MySQL documentation](#).

2. Restart the `mysql` service.

```
sudo service mysql restart
```

To create a backup copy of your existing database

1. Create a backup of your data using the `mysqldump` utility, specifying either SQL or delimited-text format.

You must specify `--master-data=2` in order to create a backup file that can be used to start replication between servers. For more information, see the [mysqldump](#) documentation.

To improve performance and ensure data integrity, use the `--order-by-primary` and `--single-transaction` options of `mysqldump`.

To avoid including the MySQL system database in the backup, do not use the `--all-databases` option with `mysqldump`. For more information, see [Creating a data snapshot using mysqldump](#) in the MySQL documentation.

Use `chmod` if necessary to make sure that the directory where the backup file is being created is writeable.

Important

On Windows, run the command window as an administrator.

- To produce SQL output, use the following command.

For Linux, macOS, or Unix:

```
sudo mysqldump \  
    --databases database_name \  
    --master-data=2 \  
    --single-transaction \  
    --order-by-primary \  
    -r backup.sql \  
    -u local_user \  
    -p password
```

For Windows:

```
mysqldump ^  
    --databases database_name ^  
    --master-data=2 ^  
    --single-transaction ^  
    --order-by-primary ^  
    -r backup.sql ^  
    -u local_user ^  
    -p password
```

- To produce delimited-text output, use the following command.

For Linux, macOS, or Unix:

```
sudo mysqldump \  
    --tab=target_directory \  
    --fields-terminated-by ',' \  
    --fields-enclosed-by '"' \  
    --lines-terminated-by 0x0d0a \  
    database_name \  
    --master-data=2 \  
    --single-transaction \  
    --order-by-primary \  
    -p password
```

For Windows:

```
mysqldump ^  
    --tab=target_directory ^  
    --fields-terminated-by "," ^  
    --fields-enclosed-by "\"" ^  
    --lines-terminated-by 0x0d0a ^  
    database_name ^
```

```
--master-data=2 ^  
--single-transaction ^  
--order-by-primary ^  
-p password
```

Note

You must create any stored procedures, triggers, functions, or events manually in your Amazon RDS database. If you have any of these objects in the database that you are copying, exclude them when you run `mysqldump` by including the following arguments with your `mysqldump` command: `--routines=0 --triggers=0 --events=0`.

When using the delimited-text format, a `CHANGE MASTER TO` comment is returned when you run `mysqldump`. This comment contains the master log file name and position. If the external instance is other than MariaDB version 10.0.2 or greater, note the values for `MASTER_LOG_FILE` and `MASTER_LOG_POS`. You need these values when setting up replication.

```
-- Position to start replication or point-in-time recovery from  
--  
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;
```

If you are using SQL format, you can get the master log file name and position in step 4 of the procedure at [Replicate between your external database and new Amazon RDS DB instance \(p. 890\)](#). If the external instance is MariaDB version 10.0.2 or greater, you can get the GTID in the next step.

2. If the external instance you are using is MariaDB version 10.0.2 or greater, you use GTID-based replication. Run `SHOW MASTER STATUS` on the external MariaDB instance to get the binary log file name and position, then convert them to a GTID by running `BINLOG_GTID_POS` on the external MariaDB instance.

```
SELECT BINLOG_GTID_POS('binary log file name', binary log file position);
```

Note the GTID returned; you need it to configure replication.

3. Compress the copied data to reduce the amount of network resources needed to copy your data to the Amazon RDS DB instance. Take note of the size of the backup file; you need this information when determining how large an Amazon EC2 instance to create. When you are done, compress the backup file using GZIP or your preferred compression utility.

- To compress SQL output, use the following command.

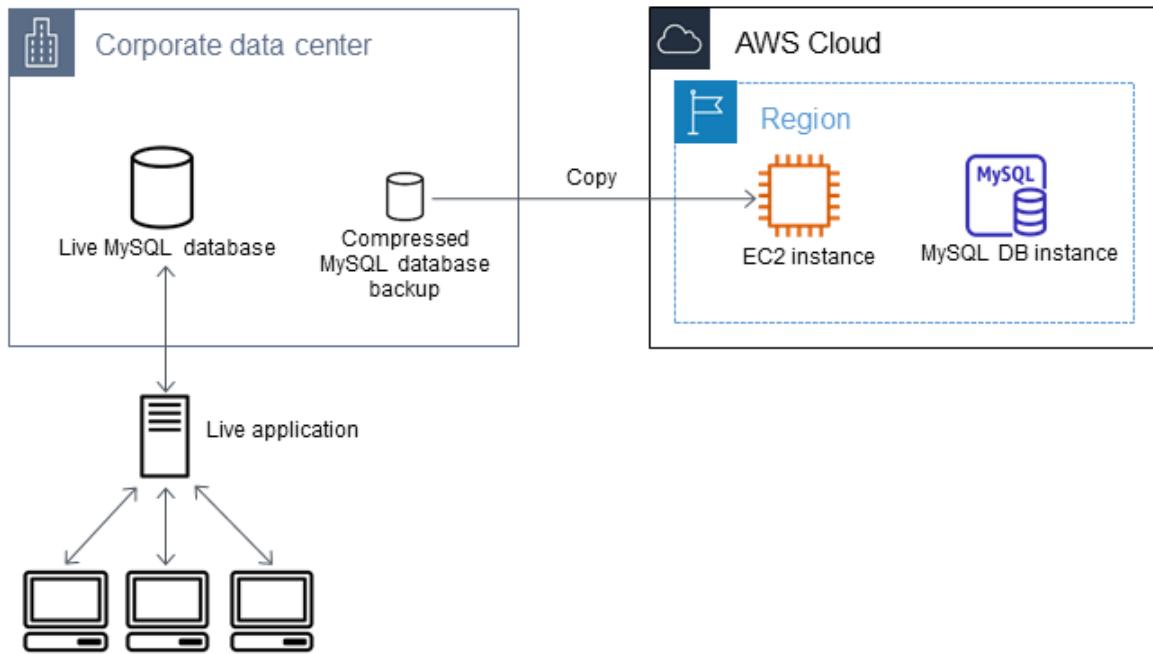

```
gzip backup.sql
```

- To compress delimited-text output, use the following command.

```
tar -zcvf backup.tar.gz target_directory
```

Create an Amazon EC2 instance and copy the compressed database

Copying your compressed database backup file to an Amazon EC2 instance takes fewer network resources than doing a direct copy of uncompressed data between database instances. After your data is in Amazon EC2, you can copy it from there directly to your MySQL or MariaDB DB instance. For you to save on the cost of network resources, your Amazon EC2 instance must be in the same AWS Region as your Amazon RDS DB instance. Having the Amazon EC2 instance in the same AWS Region as your Amazon RDS DB instance also reduces network latency during the import.

To create an Amazon EC2 instance and copy your data

1. In the AWS Region where you plan to create the RDS DB instance to run your MySQL database engine, create a VPC, a VPC security group, and a VPC subnet. Ensure that the inbound rules for your VPC security group allow the IP addresses required for your application to connect to AWS. This can be a range of IP addresses (for example, 203.0.113.0/24), or another VPC security group. You can use the [Amazon VPC management console](#) to create and manage VPCs, subnets, and security groups. For more information, see [Getting started with Amazon VPC](#) in the *Amazon Virtual Private Cloud Getting Started Guide*.

Note

Older AWS accounts can also launch instances in Amazon EC2-Classic mode. In this case, make sure that the inbound rules in the DB security group for your Amazon RDS instance allow access for your EC2-Classic instance using the Amazon EC2 private IP address. For more information, see [Working with DB security groups \(EC2-Classic platform\) \(p. 1704\)](#).

2. Open the [Amazon EC2 management console](#) and select the AWS Region to contain both your Amazon EC2 instance and your Amazon RDS DB instance. Launch an Amazon EC2 instance using the VPC, subnet, and security group that you created in Step 1. Ensure that you select an instance type with enough storage for your database backup file when it is uncompressed. For details on Amazon EC2 instances, see [Getting started with Amazon EC2 Linux instances](#) in the *Amazon Elastic Compute Cloud User Guide for Linux*.
3. To connect to your Amazon RDS DB instance from your Amazon EC2 instance, you need to edit your VPC security group, and add an inbound rule specifying the private IP address of your EC2 instance. You can find the private IP address on the **Details** tab of the **Instance** pane in the EC2 console window. To edit the VPC security group and add an inbound rule, choose **Security Groups** in the EC2 console navigation pane, choose your security group, and then add an inbound rule for MySQL/Aurora specifying the private IP address of your EC2 instance. To learn how to add an inbound rule to a VPC security group, see [Adding and removing rules](#).
4. Copy your compressed database backup file from your local system to your Amazon EC2 instance. Use `chmod` if necessary to make sure you have write permission for the target directory of the Amazon EC2 instance. You can use `scp` or an SSH client to copy the file. The following is an example:

```
$ scp -r -i key_pair.pem backup.sql.gz ec2-user@EC2_DNS:/target_directory/backup.sql.gz
```

Important

Be sure to copy sensitive data using a secure network transfer protocol.

5. Connect to your Amazon EC2 instance and install the latest updates and the MySQL client tools using the following commands:

```
sudo yum update -y  
sudo yum install mysql -y
```

For more information, see [Connect to your instance](#) in the *Amazon Elastic Compute Cloud User Guide for Linux*.

Important

This example installs the MySQL client on an Amazon Linux AMI distribution. If you want to install the MySQL client on a different distribution, such as Ubuntu or RedHat Enterprise Linux, this example won't work. For information about installing MySQL, see [Installing and Upgrading MySQL](#) in the MySQL documentation.

6. While connected to your Amazon EC2 instance, decompress your database backup file. For example:
 - To decompress SQL output, use the following command:

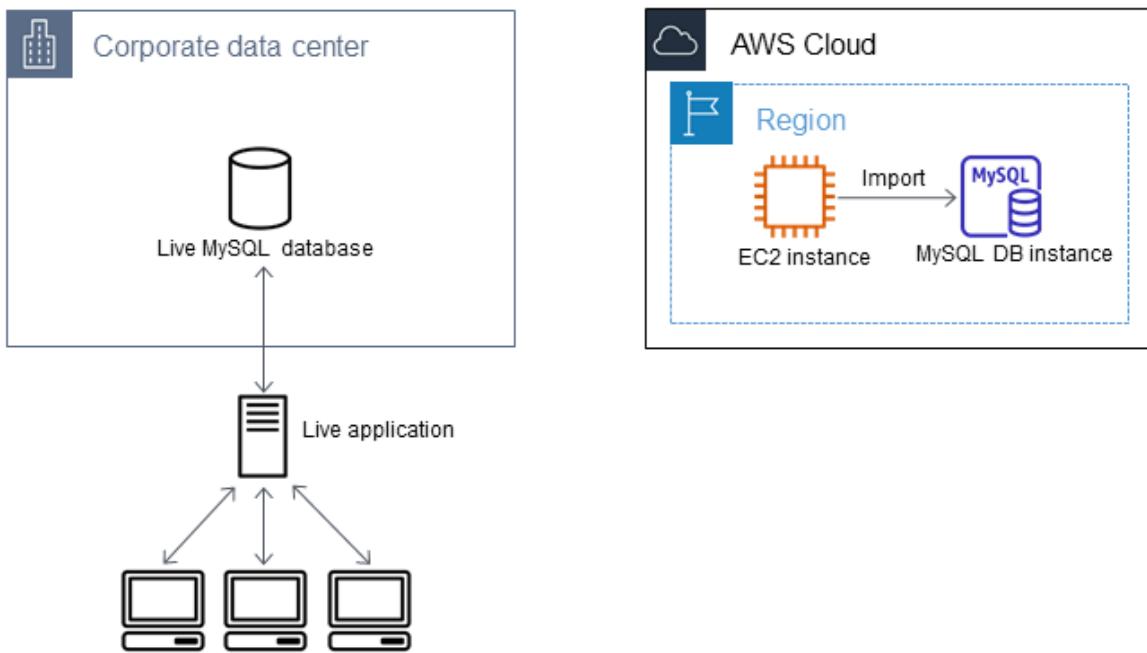

```
gzip backup.sql.gz -d
```

- To decompress delimited-text output, use the following command:

```
tar xzvf backup.tar.gz
```

Create a MySQL or MariaDB DB instance and import data from your Amazon EC2 instance

By creating a MySQL or MariaDB DB instance in the same AWS Region as your Amazon EC2 instance, you can import the database backup file from EC2 faster than over the internet.

To create a MySQL or MariaDB DB instance and import your data

1. Determine which DB instance class and what amount of storage space is required to support the expected workload for this Amazon RDS DB instance. As part of this process, decide what is sufficient space and processing capacity for your data load procedures, and also what is required to handle the production workload. You can estimate this based on the size and resources of the source MySQL or MariaDB database. For more information, see [DB instance classes \(p. 7\)](#).
2. Determine if Amazon RDS provisioned input/output operations per second (IOPS) is required to support the workloads. Provisioned IOPS storage delivers fast throughput for online transaction processing (OLTP) workloads, which are I/O intensive. For more information, see [Provisioned IOPS SSD storage \(p. 42\)](#).
3. Open the [Amazon RDS console](#). In the upper-right corner, choose the AWS Region that contains your Amazon EC2 instance.
4. In the navigation pane, choose **Databases**.
5. Choose **Create database**, and then go through the steps to choose options for your DB instance:
 - a. Make sure that **Standard Create** is chosen.
 - b. In the **Engine options** section, choose **MySQL** or **MariaDB**, as appropriate.
 - c. For **Version**, choose the version that is compatible with your source MySQL instance, as follows:
 - If your source instance is MySQL 5.1.x, the Amazon RDS DB instance must be MySQL 5.5.x.
 - If your source instance is MySQL 5.5.x, the Amazon RDS DB instance must be MySQL 5.5.x or greater.
 - If your source instance is MySQL 5.6.x, the Amazon RDS DB instance must be MySQL 5.6.x or MariaDB.
 - If your source instance is MySQL 5.7.x, the Amazon RDS DB instance must be MySQL 5.7.x, 5.6.x, or MariaDB.
 - If your source instance is MySQL 8.0.x, the Amazon RDS DB instance must be MySQL 8.0.x.
 - If your source instance is MariaDB 5.1, 5.2, or 5.3, the Amazon RDS DB instance must be MySQL 5.1.x.

- If your source instance is MariaDB 5.5 or greater, the Amazon RDS DB instance must be MariaDB.
- d. In the **Templates** section, choose **Dev/Test** to skip configuring Multi-AZ deployment and provisioned IOPS storage.
 - e. In the **Settings** section, specify the requested **DB instance identifier** and user information.
 - f. In the **DB instance class** and **Storage** sections, specify the DB instance class and allocated storage size that you want.
 - g. In the **Availability & durability** section, choose **Do not create a standby instance for Multi-AZ deployment**.
 - h. In the **Connectivity** section, choose the same virtual private cloud (VPC) and VPC security group as for your Amazon EC2 instance. This approach ensures that your Amazon EC2 instance and your Amazon RDS instance are visible to each other over the network. Set **Publicly accessible** to **Yes**. To set up replication with your source database as described later, your DB instance must be publicly accessible.

Use the default values for the other settings in this section.

In the **Backup** section, set the backup retention period to **0 days**.

Use the default values for the other settings in this section.

- i. Open the **Additional configuration** section, and specify an **Initial database name**.

Set the **Backup retention period to 0 days**

Use the default values for the other settings in this section.

- j. Choose **Create database**.

Your new DB instance appears in the **Databases** list with the status **Creating**. Wait for the **Status** of your new DB instance to show as **Available**.

Don't configure multiple Availability Zones, backup retention, or read replicas until after you have imported the database backup. When that import is done, you can set Multi-AZ and backup retention the way you want them for the production instance. For a detailed walkthrough of creating a DB instance, see [Creating an Amazon RDS DB instance \(p. 141\)](#).

6. Review the default configuration options for the Amazon RDS DB instance. In the RDS console navigation pane, choose **Parameter groups**, and then choose the magnifying glass icon next to the **default.mysqlx.x** or **default.mariadb.x** parameter group. If this parameter group doesn't have the configuration options that you want, find a different one that does or create a new parameter group. For more information on creating a parameter group, see [Working with DB parameter groups \(p. 228\)](#).

If you decide to use a different parameter group than the default, associate it with your Amazon RDS DB instance. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

7. Connect to the new Amazon RDS DB instance as the master user, and create the users required to support the administrators, applications, and services that need to access the instance. The host name for the Amazon RDS DB instance is the **Endpoint** value for this instance without including the port number, for example `mysampledb.claxc2oy9ak1.us-west-2.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.
8. Connect to your Amazon EC2 instance. For more information, see [Connect to your instance](#) in the [Amazon Elastic Compute Cloud User Guide for Linux](#).
9. Connect to your Amazon RDS DB instance as a remote host from your Amazon EC2 instance using the `mysql` command. The following is an example.

```
mysql -h host_name -P 3306 -u db_master_user -p
```

The host name is the DNS name from the Amazon RDS DB instance endpoint.

10. At the mysql prompt, run the source command and pass it the name of your database dump file to load the data into the Amazon RDS DB instance:

- For SQL format, use the following command.

```
mysql> source backup.sql;
```

- For delimited-text format, first create the database (if it isn't the default database you created when setting up the Amazon RDS DB instance).

```
mysql> create database database_name;
$ mysql> use database_name;
```

Then create the tables.

```
mysql> source table1.sql
$ mysql> source table2.sql
etc...
```

Then import the data.

```
mysql> LOAD DATA LOCAL INFILE 'table1.txt' INTO TABLE table1 FIELDS TERMINATED BY ',' 
ENCLOSED BY '\"' LINES TERMINATED BY '0x0d0a';
$ mysql> LOAD DATA LOCAL INFILE 'table2.txt' INTO TABLE table2 FIELDS TERMINATED BY ',' 
ENCLOSED BY '\"' LINES TERMINATED BY '0x0d0a';
etc...
```

To improve performance, you can perform these operations in parallel from multiple connections so that all of your tables get created and then loaded at the same time.

Note

If you used any data-formatting options with mysqldump when you initially dumped the table, you must use the same options with mysqlimport or LOAD DATA LOCAL INFILE to ensure proper interpretation of the data file contents.

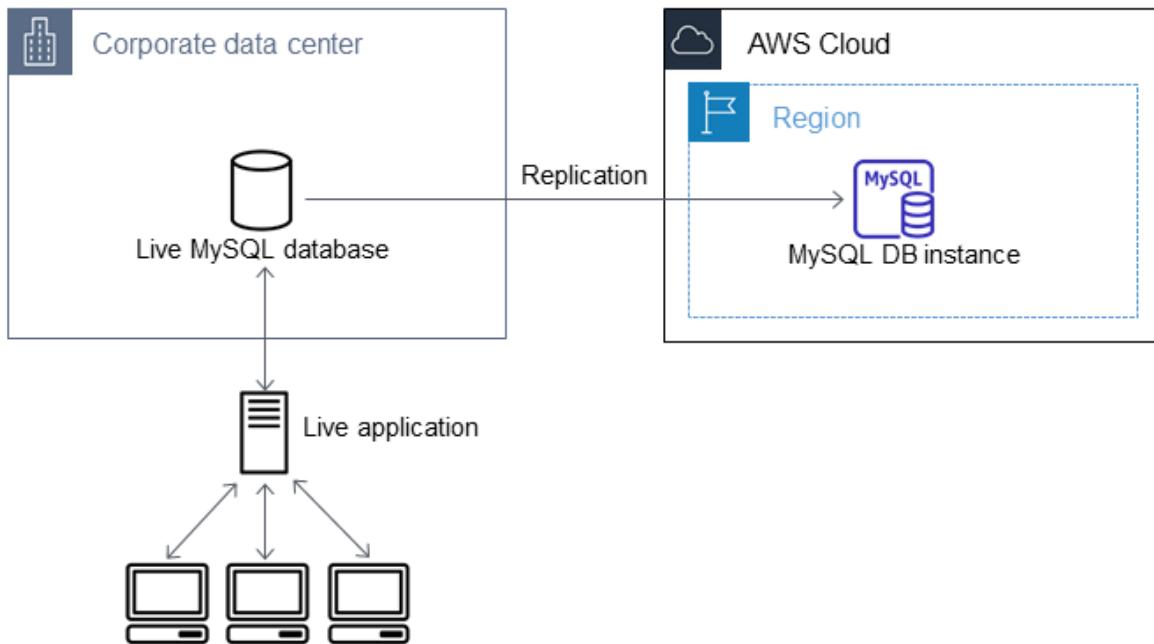

11. Run a simple SELECT query against one or two of the tables in the imported database to verify that the import was successful.

Note

If you no longer need the Amazon EC2 instance used in this procedure, terminate the EC2 instance to reduce your AWS resource usage. To terminate an EC2 instance, see [Terminating an instance](#).

Replicate between your external database and new Amazon RDS DB instance

Your source database was likely updated during the time that it took to copy and transfer the data to the MySQL or MariaDB DB instance. That being the case, you can use replication to bring the copied database up-to-date with the source database.

Note

The permissions required to start replication on an Amazon RDS DB instance are restricted and not available to your Amazon RDS master user. Because of this, you must use either the Amazon RDS [mysql.rds_set_external_master \(p. 954\)](#) command or the [mysql.rds_set_external_master_gtid \(p. 626\)](#) command to configure replication, and the [mysql.rds_start_replication \(p. 964\)](#) command to start replication between your live database and your Amazon RDS database.

To start replication

Earlier, you enabled binary logging and set a unique server ID for your source database. Now you can set up your Amazon RDS DB instance as a replica with your live database as the source replication instance.

1. In the Amazon RDS Management Console, add the IP address of the server that hosts the source database to the VPC security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see [Security groups for your VPC](#) in the *Amazon Virtual Private Cloud User Guide*.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance, so that it can communicate with your source instance. To find the IP address of the Amazon RDS DB instance, use the host command.

```
host db_instance_endpoint
```

The host name is the DNS name from the Amazon RDS DB instance endpoint, for example `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the Amazon RDS Management Console.

2. Using the client of your choice, connect to the source instance and create a user to be used for replication. This account is used solely for replication and must be restricted to your domain to improve security. The following is an example.

MySQL 5.5, 5.6, and 5.7

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

MySQL 8.0

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY  
'password';
```

3. For the source instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. For example, to grant the REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain, issue the following command.

MySQL 5.5, 5.6, and 5.7

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'  
IDENTIFIED BY 'password';
```

MySQL 8.0

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

4. If you used SQL format to create your backup file and the external instance is not MariaDB 10.0.2 or greater, look at the contents of that file.

```
cat backup.sql
```

The file includes a CHANGE MASTER TO comment that contains the master log file name and position. This comment is included in the backup file when you use the --master-data option with mysqldump. Note the values for MASTER_LOG_FILE and MASTER_LOG_POS.

```
--  
-- Position to start replication or point-in-time recovery from  
--  
-- CHANGE MASTER TO MASTER_LOG_FILE='mysql-bin-changelog.000031', MASTER_LOG_POS=107;
```

If you used delimited text format to create your backup file and the external instance is not MariaDB 10.0.2 or greater, you should already have binary log coordinates from step 1 of the procedure at [To create a backup copy of your existing database \(p. 883\)](#).

If the external instance is MariaDB 10.0.2 or greater, you should already have the GTID from which to start replication from step 2 of the procedure at [To create a backup copy of your existing database \(p. 883\)](#).

5. Make the Amazon RDS DB instance the replica. If the external instance is not MariaDB 10.0.2 or greater, connect to the Amazon RDS DB instance as the master user and identify the source database as the source replication instance by using the [mysql.rds_set_external_master \(p. 954\)](#) command. Use the master log file name and master log position that you determined in the previous step if you have a SQL format backup file. Alternatively, use the name and position that you determined when creating the backup files if you used delimited-text format. The following is an example.

```
CALL mysql.rds_set_external_master ('myserver.mydomain.com', 3306,  
'repl_user', 'password', 'mysql-bin-changelog.000031', 107, 0);
```

If the external instance is MariaDB 10.0.2 or greater, connect to the Amazon RDS DB instance as the master user and identify the source database as the source replication instance by using the

[mysql.rds_set_external_master_gtid \(p. 626\)](#) command. Use the GTID that you determined in step 2 of the procedure at [To create a backup copy of your existing database \(p. 883\)](#). The following is an example.

```
CALL mysql.rds_set_external_master_gtid ('source_server_ip_address', 3306,  
'ReplicationUser', 'password', 'GTID', 0);
```

The *source_server_ip_address* is the IP address of source replication instance. An EC2 private DNS address is currently not supported.

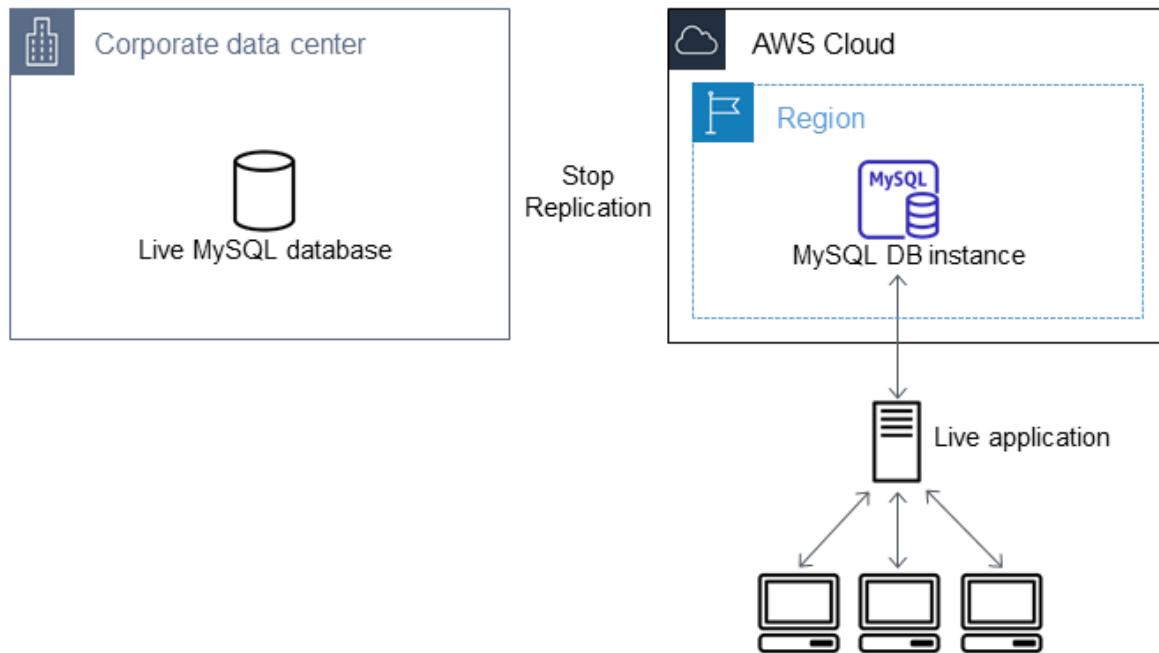

6. On the Amazon RDS DB instance, issue the [mysql.rds_start_replication \(p. 964\)](#) command to start replication.

```
CALL mysql.rds_start_replication;
```

7. On the Amazon RDS DB instance, run the [SHOW SLAVE STATUS](#) command to determine when the replica is up-to-date with the source replication instance. The results of the `SHOW SLAVE STATUS` command include the `Seconds_Behind_Master` field. When the `Seconds_Behind_Master` field returns 0, then the replica is up-to-date with the source replication instance.
8. After the Amazon RDS DB instance is up-to-date, enable automated backups so you can restore that database if needed. You can enable or modify automated backups for your Amazon RDS DB instance using the [Amazon RDS management console](#). For more information, see [Working with backups \(p. 328\)](#).

Redirect your live application to your Amazon RDS instance

After the MySQL or MariaDB DB instance is up-to-date with the source replication instance, you can now update your live application to use the Amazon RDS instance.

To redirect your live application to your MySQL or MariaDB DB instance and stop replication

1. To add the VPC security group for the Amazon RDS DB instance, add the IP address of the server that hosts the application. For more information on modifying a VPC security group, see [Security groups for your VPC](#) in the *Amazon Virtual Private Cloud User Guide*.
2. Verify that the Seconds_Behind_Master field in the [SHOW SLAVE STATUS](#) command results is 0, which indicates that the replica is up-to-date with the source replication instance.

```
SHOW SLAVE STATUS;
```

3. Close all connections to the source when their transactions complete.
4. Update your application to use the Amazon RDS DB instance. This update typically involves changing the connection settings to identify the host name and port of the Amazon RDS DB instance, the user account and password to connect with, and the database to use.
5. Stop replication for the Amazon RDS instance using the [mysql.rds_stop_replication](#) (p. 967) command.

```
CALL mysql.rds_stop_replication;
```

6. Run the [mysql.rds_reset_external_master](#) (p. 961) command on your Amazon RDS DB instance to reset the replication configuration so this instance is no longer identified as a replica.

```
CALL mysql.rds_reset_external_master;
```

7. Enable additional Amazon RDS features such as Multi-AZ support and read replicas. For more information, see [High availability \(Multi-AZ\) for Amazon RDS](#) (p. 53) and [Working with read replicas](#) (p. 278).

Importing data from any source to a MySQL or MariaDB DB instance

If you have more than 1 GiB of data to load, or if your data is coming from somewhere other than a MySQL or MariaDB database, we recommend creating flat files and loading them with `mysqldump`. `mysqldump` is another command line utility bundled with the MySQL and MariaDB client software whose purpose is to load flat files into MySQL or MariaDB. For information about `mysqldump`, see [mysqldump - a data import program](#) in the MySQL documentation.

We also recommend creating DB snapshots of the target Amazon RDS DB instance before and after the data load. Amazon RDS DB snapshots are complete backups of your DB instance that can be used to restore your DB instance to a known state. When you initiate a DB snapshot, I/O operations to your database instance are momentarily suspended while your database is backed up.

Creating a DB snapshot immediately before the load lets you restore the database to its state before the load, if you need to. A DB snapshot taken immediately after the load protects you from having to load the data again in case of a mishap and can also be used to seed new database instances.

The following list shows the steps to take. Each step is discussed in more detail below.

1. Create flat files containing the data to be loaded.
2. Stop any applications accessing the target DB instance.
3. Create a DB snapshot.
4. Consider disabling Amazon RDS automated backups.

5. Load the data using mysqlimport.
6. Enable automated backups again.

Step 1: Create flat files containing the data to be loaded

Use a common format, such as CSV (Comma-Separated Values), to store the data to be loaded. Each table must have its own file; data for multiple tables cannot be combined in the same file. Give each file the same name as the table it corresponds to. The file extension can be anything you like. For example, if the table name is "sales", the file name could be "sales.csv" or "sales.txt", but not "sales_01.csv".

Whenever possible, order the data by the primary key of the table being loaded. This drastically improves load times and minimizes disk storage requirements.

The speed and efficiency of this procedure is dependent upon keeping the size of the files small. If the uncompressed size of any individual file is larger than 1 GiB, split it into multiple files and load each one separately.

On Unix-like systems (including Linux), use the 'split' command. For example, the following command splits the sales.csv file into multiple files of less than 1 GiB, splitting only at line breaks (-C 1024m). The new files are named sales.part_00, sales.part_01, and so on.

```
split -C 1024m -d sales.csv sales.part_
```

Similar utilities are available on other operating systems.

Step 2: Stop any applications accessing the target DB instance

Before starting a large load, stop all application activity accessing the target DB instance that you plan to load to. We recommend this particularly if other sessions will be modifying the tables being loaded or tables they reference. Doing this reduces the risk of constraint violations occurring during the load and improves load performance. It also makes it possible to restore the database instance to the point just before the load without losing changes made by processes not involved in the load.

Of course, this might not be possible or practical. If you are unable to stop applications from accessing the DB instance before the load, take steps to ensure the availability and integrity of your data. The specific steps required vary greatly depending upon specific use cases and site requirements.

Step 3: Create a DB snapshot

If you plan to load data into a new DB instance that contains no data, you can skip this step. Otherwise, creating a DB snapshot of your DB instance allows you to restore the DB instance to the point just before the load, if it becomes necessary. As previously mentioned, when you initiate a DB snapshot, I/O operations to your database instance are suspended for a few minutes while the database is backed up.

In the example below, we use the AWS CLI `create-db-snapshot` command to create a DB snapshot of our AcmeRDS instance and give the DB snapshot the identifier "preload".

For Linux, macOS, or Unix:

```
aws rds create-db-snapshot \  
--db-instance-identifier AcmeRDS \  
--db-snapshot-identifier preload
```

For Windows:

```
aws rds create-db-snapshot ^
```

```
--db-instance-identifier AcmeRDS ^  
--db-snapshot-identifier preload
```

You can also use the restore from DB snapshot functionality in order to create test database instances for dry runs or to "undo" changes made during the load.

Keep in mind that restoring a database from a DB snapshot creates a new DB instance that, like all DB instances, has a unique identifier and endpoint. If you need to restore the database instance without changing the endpoint, you must first delete the DB instance so that the endpoint can be reused.

For example, to create a DB instance for dry runs or other testing, you would give the DB instance its own identifier. In the example, "AcmeRDS-2" is the identifier and we would connect to the database instance using the endpoint associated with AcmeRDS-2.

For Linux, macOS, or Unix:

```
aws rds restore-db-instance-from-db-snapshot \  
  --db-instance-identifier AcmeRDS-2 \  
  --db-snapshot-identifier preload
```

For Windows:

```
aws rds restore-db-instance-from-db-snapshot ^  
  --db-instance-identifier AcmeRDS-2 ^  
  --db-snapshot-identifier preload
```

To reuse the existing endpoint, we must first delete the database instance and then give the restored database the same identifier.

For Linux, macOS, or Unix:

```
aws rds delete-db-instance \  
  --db-instance-identifier AcmeRDS \  
  --final-db-snapshot-identifier AcmeRDS-Final  
  
aws rds restore-db-instance-from-db-snapshot \  
  --db-instance-identifier AcmeRDS \  
  --db-snapshot-identifier preload
```

For Windows:

```
aws rds delete-db-instance ^  
  --db-instance-identifier AcmeRDS ^  
  --final-db-snapshot-identifier AcmeRDS-Final  
  
aws rds restore-db-instance-from-db-snapshot ^  
  --db-instance-identifier AcmeRDS ^  
  --db-snapshot-identifier preload
```

The example takes a final DB snapshot of the database instance before deleting it. This is optional, but recommended.

Step 4: Consider disabling Amazon RDS automated backups

Warning

Do not disable automated backups if you need the ability to perform point-in-time recovery.

Disabling automated backups erases all existing backups, so point-in-time recovery is not possible after automated backups have been disabled. Disabling automated backups is a performance optimization

and is not required for data loads. Manual DB snapshots are not affected by disabling automated backups. All existing manual DB snapshots are still available for restore.

Disabling automated backups reduces load time by about 25 percent and reduce the amount of storage space required during the load. If you plan to load data into a new DB instance that contains no data, disabling backups is an easy way to speed up the load and avoid using the additional storage needed for backups. However, if you plan to load into a DB instance that already contains data, weigh the benefits of disabling backups against the impact of losing the ability to perform point-in-time-recovery.

DB instances have automated backups enabled by default (with a one day retention period). In order to disable automated backups, you must set the backup retention period to zero. After the load, you can re-enable backups by setting the backup retention period to a non-zero value. In order to enable or disable backups, Amazon RDS must shut the DB instance down and restart it in order to turn MySQL or MariaDB logging on or off.

Use the AWS CLI `modify-db-instance` command to set the backup retention to zero and apply the change immediately. Setting the retention period to zero requires a DB instance restart, so wait until the restart has completed before proceeding.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier AcmeRDS \
--apply-immediately \
--backup-retention-period 0
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier AcmeRDS ^
--apply-immediately ^
--backup-retention-period 0
```

You can check the status of your DB instance with the AWS CLI `describe-db-instances` command. The example displays the DB instance status of the AcmeRDS DB instance.

```
aws rds describe-db-instances --db-instance-identifier AcmeRDS --query "*[].{DBInstanceStatus:DBInstanceState}"
```

When the DB instance status is available, you're ready to proceed.

Step 5: Load the data

Use the `mysqlimport` utility to load the flat files into Amazon RDS. In the example we tell `mysqlimport` to load all of the files named "sales" with an extension starting with "part_". This is a convenient way to load all of the files created in the "split" example. Use the `--compress` option to minimize network traffic. The `--fields-terminated-by=,` option is used for CSV files and the `--local` option specifies that the incoming data is located on the client. Without the `--local` option, the Amazon RDS DB instance looks for the data on the database host, so always specify the `--local` option.

For Linux, macOS, or Unix:

```
mysqlimport --local \
--compress \
--user=username \
--password \
--host=hostname \
```

```
--fields-terminated-by=',' Acme sales.part_*
```

For Windows:

```
mysqlimport --local ^
--compress ^
--user=username ^
--password ^
--host=hostname ^
--fields-terminated-by="," Acme sales.part_*
```

For very large data loads, take additional DB snapshots periodically between loading files and note which files have been loaded. If a problem occurs, you can easily resume from the point of the last DB snapshot, avoiding lengthy reloads.

Step 6: Enable Amazon RDS automated backups

After the load is finished, re-enable Amazon RDS automated backups by setting the backup retention period back to its pre-load value. As noted earlier, Amazon RDS restarts the DB instance, so be prepared for a brief outage.

In the example, we use the AWS CLI modify-db-instance command to enable automated backups for the AcmeRDS DB instance and set the retention period to 1 day.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier AcmeRDS \
--backup-retention-period 1 \
--apply-immediately
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier AcmeRDS ^
--backup-retention-period 1 ^
--apply-immediately
```

Working with MySQL replication in Amazon RDS

You usually use read replicas to configure replication between Amazon RDS DB instances. For general information about read replicas, see [Working with read replicas \(p. 278\)](#). For specific information about working with read replicas on Amazon RDS for MySQL, see [Working with MySQL read replicas \(p. 899\)](#).

You can use global transaction identifiers (GTIDs) for replication with Amazon RDS for MySQL. For more information, see [Using GTID-based replication for RDS for MySQL \(p. 910\)](#).

You can also set up replication between an Amazon RDS for MySQL DB instance and a MySQL or MariaDB instance that is external to Amazon RDS. For information about configuring replication with an external source, see [Replication with a MySQL or MariaDB instance running external to Amazon RDS \(p. 914\)](#).

For any of these replication options, you can use either row-based replication, statement-based, or mixed replication. Row-based replication only replicates the changed rows that result from a SQL statement. Statement-based replication replicates the entire SQL statement. Mixed replication uses statement-based replication when possible, but switches to row-based replication when SQL statements that are unsafe for statement-based replication are run. In most cases, mixed replication is recommended. The binary log format of the DB instance determines whether replication is row-based, statement-based, or mixed. For information about setting the binary log format, see [Setting the binary logging format \(p. 524\)](#).

Note

You can configure replication to import databases from a MySQL or MariaDB instance that is external to Amazon RDS, or to export databases to such instances. For more information, see [Importing data to an Amazon RDS MySQL or MariaDB DB instance with reduced downtime \(p. 881\)](#) and [Exporting data from a MySQL DB instance by using replication \(p. 921\)](#).

Topics

- [Monitoring MySQL read replicas \(p. 908\)](#)
- [Starting and stopping replication with MySQL read replicas \(p. 908\)](#)
- [Troubleshooting a MySQL read replica problem \(p. 908\)](#)

Read replica configuration with MySQL

Before a MySQL DB instance can serve as a replication source, make sure to enable automatic backups on the source DB instance. To do this, set the backup retention period to a value other than 0. This

requirement also applies to a read replica that is the source DB instance for another read replica. Automatic backups are supported only for read replicas running any version of MySQL 5.6 and later. You can configure replication based on binary log coordinates for a MySQL DB instance.

On Amazon RDS for MySQL version 5.7.23 and later MySQL 5.7 versions, you can configure replication using global transaction identifiers (GTIDs). For more information, see [Using GTID-based replication for RDS for MySQL \(p. 910\)](#).

You can create up to five read replicas from one DB instance. For replication to operate effectively, each read replica should have the same amount of compute and storage resources as the source DB instance. If you scale the source DB instance, also scale the read replicas.

If a read replica is running any version of MySQL 5.6 and later, you can specify it as the source DB instance for another read replica. For example, you can create ReadReplica1 from MyDBInstance, and then create ReadReplica2 from ReadReplica1. Updates made to MyDBInstance are replicated to ReadReplica1 and then replicated from ReadReplica1 to ReadReplica2. You can't have more than four instances involved in a replication chain. For example, you can create ReadReplica1 from MySourceDBInstance, and then create ReadReplica2 from ReadReplica1, and then create ReadReplica3 from ReadReplica2, but you can't create a ReadReplica4 from ReadReplica3.

If you promote a MySQL read replica that is in turn replicating to other read replicas, those read replicas remain active. Consider an example where MyDBInstance1 replicates to MyDBInstance2, and MyDBInstance2 replicates to MyDBInstance3. If you promote MyDBInstance2, replication from MyDBInstance1 to MyDBInstance2 no longer occurs, but MyDBInstance2 still replicates to MyDBInstance3.

To enable automatic backups on a read replica for Amazon RDS for MySQL version 5.6 and later, first create the read replica. Then modify the read replica to enable automatic backups.

You can run multiple read replica create or delete actions at the same time that reference the same source DB instance. To do this, stay within the limit of five read replicas for each source instance.

A read replica of a MySQL DB instance can't use a lower DB engine version than its source DB instance.

Preparing MySQL DB instances that use MyISAM

If your MySQL DB instance uses a nontransactional engine such as MyISAM, you need to perform the following steps to successfully set up your read replica. These steps are required to make sure that the read replica has a consistent copy of your data. These steps are not required if all of your tables use a transactional engine such as InnoDB.

1. Stop all data manipulation language (DML) and data definition language (DDL) operations on non-transactional tables in the source DB instance and wait for them to complete. SELECT statements can continue running.
2. Flush and lock the tables in the source DB instance.
3. Create the read replica using one of the methods in the following sections.
4. Check the progress of the read replica creation using, for example, the `DescribeDBInstances` API operation. Once the read replica is available, unlock the tables of the source DB instance and resume normal database operations.

Configuring replication filters with MySQL

You can use replication filters to specify which databases and tables are replicated with a read replica. Replication filters can include databases and tables in replication or exclude them from replication.

The following are some use cases for replication filters:

- To reduce the size of a read replica. With replication filtering, you can exclude the databases and tables that aren't needed on the read replica.

- To exclude databases and tables from read replicas for security reasons.
- To replicate different databases and tables for specific use cases at different read replicas. For example, you might use specific read replicas for analytics or sharding.
- For a DB instance that has read replicas in different AWS Regions, to replicate different databases or tables in different AWS Regions.

Topics

- [Replication filtering parameters for Amazon RDS for MySQL \(p. 901\)](#)
- [Replication filtering limitations for Amazon RDS for MySQL \(p. 902\)](#)
- [Replication filtering examples for Amazon RDS for MySQL \(p. 902\)](#)
- [Viewing the replication filters for a read replica \(p. 905\)](#)

Replication filtering parameters for Amazon RDS for MySQL

To configure replication filters, set the following replication filtering parameters on the read replica:

- `replicate-do-db` – Replicate changes to the specified databases. When you set this parameter for a read replica, only the databases specified in the parameter are replicated.
- `replicate-ignore-db` – Don't replicate changes to the specified databases. When the `replicate-do-db` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-do-table` – Replicate changes to the specified tables. When you set this parameter for a read replica, only the tables specified in the parameter are replicated. Also, when the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- `replicate-ignore-table` – Don't replicate changes to the specified tables. When the `replicate-do-table` parameter is set for a read replica, this parameter isn't evaluated.
- `replicate-wild-do-table` – Replicate tables based on the specified database and table name patterns. The % and _ wildcard characters are supported. When the `replicate-do-db` or `replicate-ignore-db` parameter is set, make sure to include the database that includes the specified tables in replication with the read replica.
- `replicate-wild-ignore-table` – Don't replicate tables based on the specified database and table name patterns. The % and _ wildcard characters are supported. When the `replicate-do-table` or `replicate-wild-do-table` parameter is set for a read replica, this parameter isn't evaluated.

The parameters are evaluated in the order that they are listed. For more information about how these parameters work, see the MySQL documentation:

- For general information, see [Replica Server Options and Variables](#).
- For information about how database replication filtering parameters are evaluated, see [Evaluation of Database-Level Replication and Binary Logging Options](#).
- For information about how table replication filtering parameters are evaluated, see [Evaluation of Table-Level Replication Options](#).

By default, each of these parameters has an empty value. On each read replica, you can use these parameters to set, change, and delete replication filters. When you set one of these parameters, separate each filter from others with a comma.

You can use the % and _ wildcard characters in the `replicate-wild-do-table` and `replicate-wild-ignore-table` parameters. The % wildcard matches any number of characters, and the _ wildcard matches only one character.

The binary logging format of the source DB instance is important for replication because it determines the record of data changes. The setting of the `binlog_format` parameter determines whether the replication is row-based or statement-based. For more information, see [Setting the binary logging format \(p. 524\)](#).

Note

All data definition language (DDL) statements are replicated as statements, regardless of the `binlog_format` setting on the source DB instance.

Replication filtering limitations for Amazon RDS for MySQL

The following limitations apply to replication filtering for Amazon RDS for MySQL:

- Each replication filtering parameter has a 2,000-character limit.
- Commas aren't supported in replication filters.
- The MySQL `--binlog-do-db` and `--binlog-ignore-db` options for binary log filtering aren't supported.
- Replication filtering doesn't support XA transactions.

For more information, see [Restrictions on XA Transactions](#) in the MySQL documentation.

- Replication filtering is supported for Amazon RDS for MySQL version 8.0.17 and higher 8.0 versions and version 5.7.26 and higher 5.7 versions.
- Replication filtering isn't supported for Amazon RDS for MySQL version 5.5 or 5.6.

Replication filtering examples for Amazon RDS for MySQL

To configure replication filtering for a read replica, modify the replication filtering parameters in the parameter group associated with the read replica.

Note

You can't modify a default parameter group. If the read replica is using a default parameter group, create a new parameter group and associate it with the read replica. For more information on DB parameter groups, see [Working with DB parameter groups \(p. 228\)](#).

You can set parameters in a parameter group using the AWS Management Console, AWS CLI, or RDS API. For information about setting parameters, see [Modifying parameters in a DB parameter group \(p. 232\)](#). When you set parameters in a parameter group, all of the DB instances associated with the parameter group use the parameter settings. If you set the replication filtering parameters in a parameter group, make sure that the parameter group is associated only with read replicas. Leave the replication filtering parameters empty for source DB instances.

The following examples set the parameters using the AWS CLI. These examples set `ApplyMethod` to `immediate` so that the parameter changes occur immediately after the CLI command completes. If you want a pending change to be applied after the read replica is rebooted, set `ApplyMethod` to `pending-reboot`.

The following examples set replication filters:

- [Including databases in replication](#)
- [Including tables in replication](#)
- [Including tables in replication with wildcard characters](#)
- [Escaping wildcard characters in names](#)
- [Excluding databases from replication](#)
- [Excluding tables from replication](#)
- [Excluding tables from replication using wildcard characters](#)

Example Including databases in replication

The following example includes the `mydb1` and `mydb2` databases in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "[{"ParameterName": "replicate-do-db", "ParameterValue": "mydb1,mydb2",
"ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
--parameters "[{"ParameterName": "replicate-do-db", "ParameterValue": "mydb1,mydb2",
"ApplyMethod":"immediate"}]"
```

Example Including tables in replication

The following example includes the `table1` and `table2` tables in database `mydb1` in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "[{"ParameterName": "replicate-do-table", "ParameterValue":
"mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
--parameters "[{"ParameterName": "replicate-do-table", "ParameterValue":
"mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"}]"
```

Example Including tables in replication using wildcard characters

The following example includes tables with names that begin with `orders` and `returns` in database `mydb` in replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue":
"mydb.orders%,mydb_returns%", "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
--parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue":
"mydb.orders%,mydb_returns%", "ApplyMethod":"immediate"}]"
```

Example Escaping wildcard characters in names

The following example shows you how to use the escape character \ to escape a wildcard character that is part of a name.

Assume that you have several table names in database mydb1 that start with my_table, and you want to include these tables in replication. The table names include an underscore, which is also a wildcard character, so the example escapes the underscore in the table names.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue": "my\_table%", "ApplyMethod": "immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
--parameters "[{"ParameterName": "replicate-wild-do-table", "ParameterValue": "my\_table%", "ApplyMethod": "immediate"}]"
```

Example Excluding databases from replication

The following example excludes the mydb1 and mydb2 databases from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "[{"ParameterName": "replicate-ignore-db", "ParameterValue": "mydb1,mydb2", "ApplyMethod": "immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
--parameters "[{"ParameterName": "replicate-ignore-db", "ParameterValue": "mydb1,mydb2", "ApplyMethod": "immediate"}]"
```

Example Excluding tables from replication

The following example excludes tables table1 and table2 in database mydb1 from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "[{"ParameterName": "replicate-ignore-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod": "immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
--parameters "[{"ParameterName": "replicate-ignore-table", "ParameterValue": "mydb1.table1,mydb1.table2", "ApplyMethod":"immediate"}]"
```

Example Excluding tables from replication using wildcard characters

The following example excludes tables with names that begin with `orders` and `returns` in database `mydb` from replication.

For Linux, macOS, or Unix:

```
aws rds modify-db-parameter-group \
--db-parameter-group-name myparametergroup \
--parameters "[{"ParameterName": "replicate-wild-ignore-table", "ParameterValue": "mydb.orders%,mydb_returns%", "ApplyMethod":"immediate"}]"
```

For Windows:

```
aws rds modify-db-parameter-group ^
--db-parameter-group-name myparametergroup ^
--parameters "[{"ParameterName": "replicate-wild-ignore-table", "ParameterValue": "mydb.orders%,mydb_returns%", "ApplyMethod":"immediate"}]"
```

Viewing the replication filters for a read replica

You can view the replication filters for a read replica in the following ways:

- Check the settings of the replication filtering parameters in the parameter group associated with the read replica.

For instructions, see [Viewing parameter values for a DB parameter group \(p. 239\)](#).

- In a MySQL client, connect to the read replica and run the `SHOW SLAVE STATUS` statement.

In the output, the following fields show the replication filters for the read replica:

- `Replicate_Do_DB`
- `Replicate_Ignore_DB`
- `Replicate_Do_Table`
- `Replicate_Ignore_Table`
- `Replicate_Wild_Do_Table`
- `Replicate_Wild_Ignore_Table`

For more information about these fields, see [Checking Replication Status](#) in the MySQL documentation.

Configuring delayed replication with MySQL

You can use delayed replication as a strategy for disaster recovery. With delayed replication, you specify the minimum amount of time, in seconds, to delay replication from the source to the read replica. In the event of a disaster, such as a table deleted unintentionally, you complete the following steps to recover from the disaster quickly:

- Stop replication to the read replica before the change that caused the disaster is sent to it.

Use the [mysql.rds_stop_replication \(p. 967\)](#) stored procedure to stop replication.

- Start replication and specify that replication stops automatically at a log file location.

You specify a location just before the disaster using the [mysql.rds_start_replication_until \(p. 965\)](#) stored procedure.

- Promote the read replica to be the new source DB instance by using the instructions in [Promoting a read replica to be a standalone DB instance \(p. 285\)](#).

Note

- On Amazon RDS for MySQL 5.7, delayed replication is supported for MySQL 5.7.22 and later. On Amazon RDS for MySQL 5.6, delayed replication is supported for MySQL 5.6.40 and later. Delayed replication is not supported on Amazon RDS for MySQL 8.0.
- Use stored procedures to configure delayed replication. You can't configure delayed replication with the AWS Management Console, the AWS CLI, or the Amazon RDS API.
- On Amazon RDS for MySQL 5.7.23 and later MySQL 5.7 versions, you can use replication based on global transaction identifiers (GTIDs) in a delayed replication configuration. If you use GTID-based replication, use the [mysql.rds_start_replication_until_gtid \(p. 966\)](#) stored procedure instead of the [mysql.rds_start_replication_until \(p. 965\)](#) stored procedure. For more information about GTID-based replication, see [Using GTID-based replication for RDS for MySQL \(p. 910\)](#).

Topics

- [Configuring delayed replication during read replica creation \(p. 906\)](#)
- [Modifying delayed replication for an existing read replica \(p. 906\)](#)
- [Setting a location to stop replication to a read replica \(p. 907\)](#)

Configuring delayed replication during read replica creation

To configure delayed replication for any future read replica created from a DB instance, run the [mysql.rds_set_configuration \(p. 972\)](#) stored procedure with the `target_delay` parameter.

To configure delayed replication during read replica creation

- Using a MySQL client, connect to the MySQL DB instance to be the source for read replicas as the master user.
- Run the [mysql.rds_set_configuration \(p. 972\)](#) stored procedure with the `target_delay` parameter.

For example, run the following stored procedure to specify that replication is delayed by at least one hour (3,600 seconds) for any read replica created from the current DB instance.

```
call mysql.rds_set_configuration('target_delay', 3600);
```

Note

After running this stored procedure, any read replica you create using the AWS CLI or Amazon RDS API is configured with replication delayed by the specified number of seconds.

Modifying delayed replication for an existing read replica

To modify delayed replication for an existing read replica, run the [mysql.rds_set_source_delay \(p. 964\)](#) stored procedure.

To modify delayed replication for an existing read replica

1. Using a MySQL client, connect to the read replica as the master user.
2. Use the [mysql.rds_stop_replication \(p. 967\)](#) stored procedure to stop replication.
3. Run the [mysql.rds_set_source_delay \(p. 964\)](#) stored procedure.

For example, run the following stored procedure to specify that replication to the read replica is delayed by at least one hour (3600 seconds).

```
call mysql.rds_set_source_delay(3600);
```

4. Use the [mysql.rds_start_replication \(p. 964\)](#) stored procedure to start replication.

Setting a location to stop replication to a read replica

After stopping replication to the read replica, you can start replication and then stop it at a specified binary log file location using the [mysql.rds_start_replication_until \(p. 965\)](#) stored procedure.

To start replication to a read replica and stop replication at a specific location

1. Using a MySQL client, connect to the source MySQL DB instance as the master user.
2. Run the [mysql.rds_start_replication_until \(p. 965\)](#) stored procedure.

The following example initiates replication and replicates changes until it reaches location 120 in the `mysql-bin-changelog.000777` binary log file. In a disaster recovery scenario, assume that location 120 is just before the disaster.

```
call mysql.rds_start_replication_until(
    'mysql-bin-changelog.000777',
    120);
```

Replication stops automatically when the stop point is reached. The following RDS event is generated:
`Replication has been stopped since the replica reached the stop point specified by the rds_start_replication_until stored procedure.`

After replication is stopped, in a disaster recovery scenario, you can [Promoting a read replica to be a standalone DB instance \(p. 285\)](#) promote the read replica to be the new source DB instance. For information about promoting the read replica, see [Promoting a read replica to be a standalone DB instance \(p. 285\)](#).

Read replica updates with MySQL

Read replicas are designed to support read queries, but you might need occasional updates. For example, you might need to add an index to optimize the specific types of queries accessing the replica. You can enable updates by setting the `read_only` parameter to 0 in the DB parameter group for the read replica. Be careful when disabling read-only on a read replica because it can cause problems if the read replica becomes incompatible with the source DB instance. Change the value of the `read_only` parameter back to 1 as soon as possible.

Multi-AZ read replica deployments with MySQL

You can create a read replica from either single-AZ or Multi-AZ DB instance deployments. You use Multi-AZ deployments to improve the durability and availability of critical data, but you can't use the Multi-AZ secondary to serve read-only queries. Instead, you can create read replicas from high-traffic Multi-AZ DB

instances to offload read-only queries. If the source instance of a Multi-AZ deployment fails over to the secondary, any associated read replicas automatically switch to use the secondary (now primary) as their replication source. For more information, see [High availability \(Multi-AZ\) for Amazon RDS \(p. 53\)](#).

You can create a read replica as a Multi-AZ DB instance. Amazon RDS creates a standby of your replica in another Availability Zone for failover support for the replica. Creating your read replica as a Multi-AZ DB instance is independent of whether the source database is a Multi-AZ DB instance.

Note

To create a read replica as a Multi-AZ DB instance, the DB instance must be MySQL 5.6 or later.

Monitoring MySQL read replicas

For MySQL read replicas, you can monitor replication lag in Amazon CloudWatch by viewing the Amazon RDS `ReplicaLag` metric. The `ReplicaLag` metric reports the value of the `Seconds_Behind_Master` field of the `SHOW SLAVE STATUS` command.

Common causes for replication lag for MySQL are the following:

- A network outage.
- Writing to tables that have different indexes on a read replica. If the `read_only` parameter is set to 0 on the read replica, replication can break if the read replica becomes incompatible with the source DB instance. After you've performed maintenance tasks on the read replica, we recommend that you set the `read_only` parameter back to 1.
- Using a nontransactional storage engine such as MyISAM. Replication is only supported for the InnoDB storage engine on MySQL.

When the `ReplicaLag` metric reaches 0, the replica has caught up to the source DB instance. If the `ReplicaLag` metric returns -1, then replication is currently not active. `ReplicaLag = -1` is equivalent to `Seconds_Behind_Master = NULL`.

Starting and stopping replication with MySQL read replicas

You can stop and restart the replication process on an Amazon RDS DB instance by calling the system stored procedures [mysql.rds_stop_replication \(p. 967\)](#) and [mysql.rds_start_replication \(p. 964\)](#). You can do this when replicating between two Amazon RDS instances for long-running operations such as creating large indexes. You also need to stop and start replication when importing or exporting databases. For more information, see [Importing data to an Amazon RDS MySQL or MariaDB DB instance with reduced downtime \(p. 881\)](#) and [Exporting data from a MySQL DB instance by using replication \(p. 921\)](#).

If replication is stopped for more than 30 consecutive days, either manually or due to a replication error, Amazon RDS terminates replication between the source DB instance and all read replicas. It does so to prevent increased storage requirements on the source DB instance and long failover times. The read replica DB instance is still available. However, replication can't be resumed because the binary logs required by the read replica are deleted from the source DB instance after replication is terminated. You can create a new read replica for the source DB instance to reestablish replication.

Troubleshooting a MySQL read replica problem

For MySQL DB instances, in some cases read replicas present replication errors or data inconsistencies between the read replica and its source DB instance. This problem occurs when some binary log (binlog) events or InnoDB redo logs aren't flushed during a failure of the read replica or the source DB instance. In these cases, manually delete and recreate the read replicas. You can reduce the chance of this happening by setting the following parameter values: `sync_binlog=1` and `innodb_flush_log_at_trx_commit=1`. These settings might reduce performance, so test their

impact before implementing the changes in a production environment. For MySQL 5.5, `sync_binlog` defaults to 0, but in MySQL 5.6 and later, problems are less likely to occur because these parameters are all set to the recommended values by default.

The replication technologies for MySQL are asynchronous. Because they are asynchronous, occasional `BinLogDiskUsage` increases on the source DB instance and `ReplicaLag` on the read replica are to be expected. For example, a high volume of write operations to the source DB instance can occur in parallel. In contrast, write operations to the read replica are serialized using a single I/O thread, which can lead to a lag between the source instance and read replica. For more information about read-only replicas in the MySQL documentation, see [Replication implementation details](#).

You can do several things to reduce the lag between updates to a source DB instance and the subsequent updates to the read replica, such as the following:

- Sizing a read replica to have a storage size and DB instance class comparable to the source DB instance.
- Ensuring that parameter settings in the DB parameter groups used by the source DB instance and the read replica are compatible. For more information and an example, see the discussion of the `max_allowed_packet` parameter later in this section.

Amazon RDS monitors the replication status of your read replicas and updates the `Replication State` field of the read replica instance to `Error` if replication stops for any reason. An example might be if DML queries run on your read replica conflict with the updates made on the source DB instance.

You can review the details of the associated error thrown by the MySQL engine by viewing the `Replication Error` field. Events that indicate the status of the read replica are also generated, including [RDS-EVENT-0045 \(p. 492\)](#), [RDS-EVENT-0046 \(p. 492\)](#), and [RDS-EVENT-0047 \(p. 491\)](#). For more information about events and subscribing to events, see [Using Amazon RDS event notification \(p. 487\)](#). If a MySQL error message is returned, review the error number in the [MySQL error message documentation](#).

One common issue that can cause replication errors is when the value for the `max_allowed_packet` parameter for a read replica is less than the `max_allowed_packet` parameter for the source DB instance. The `max_allowed_packet` parameter is a custom parameter that you can set in a DB parameter group. You use `max_allowed_packet` to specify the maximum size of DML code that can be run on the database. In some cases, the `max_allowed_packet` value in the DB parameter group associated with a read replica is smaller than the `max_allowed_packet` value in the DB parameter group associated with the source DB instance. In these cases, the replication process can throw the error `Packet bigger than 'max_allowed_packet' bytes` and stop replication. To fix the error, have the source DB instance and read replica use DB parameter groups with the same `max_allowed_packet` parameter values.

Other common situations that can cause replication errors include the following:

- Writing to tables on a read replica. In some cases, you might create indexes on a read replica that are different from the indexes on the source DB instance. If you do, set the `read_only` parameter to 0 to create the indexes. If you write to tables on the read replica, it might break replication if the read replica becomes incompatible with the source DB instance. After you perform maintenance tasks on the read replica, we recommend that you set the `read_only` parameter back to 1.
- Using a non-transactional storage engine such as MyISAM. Read replicas require a transactional storage engine. Replication is only supported for the InnoDB storage engine on MySQL.
- Using unsafe nondeterministic queries such as `SYSDATE()`. For more information, see [Determination of safe and unsafe statements in binary logging](#).

If you decide that you can safely skip an error, you can follow the steps described in the section [Skipping the current replication error \(p. 933\)](#). Otherwise, you can first delete the read replica. Then you create

an instance using the same DB instance identifier so that the endpoint remains the same as that of your old read replica. If a replication error is fixed, the `Replication State` changes to *replicating*.

Using GTID-based replication for RDS for MySQL

Following, you can learn how to use global transaction identifiers (GTIDs) with binary log (binlog) replication among RDS for MySQL DB instances.

If you use binlog replication and aren't familiar with GTID-based replication with MySQL, see [Replication with global transaction identifiers](#) in the MySQL documentation for background.

Note

GTID-based replication is supported for RDS for MySQL version 5.7.23 and later MySQL 5.7 versions. All MySQL DB instances in a replication configuration must meet this requirement. GTID-based replication isn't supported for RDS for MySQL 5.5, 5.6, or 8.0.

Topics

- [Overview of global transaction identifiers \(GTIDs\) \(p. 910\)](#)
- [Parameters for GTID-based replication \(p. 910\)](#)
- [Configuring GTID-based replication for new read replicas \(p. 911\)](#)
- [Configuring GTID-based replication for existing read replicas \(p. 912\)](#)
- [Disabling GTID-based replication for a MySQL DB instance with read replicas \(p. 913\)](#)

Note

For information about configuring GTID-based replication with an external database, see [Replication with a MySQL or MariaDB instance running external to Amazon RDS \(p. 914\)](#).

Overview of global transaction identifiers (GTIDs)

Global transaction identifiers (GTIDs) are unique identifiers generated for committed MySQL transactions. You can use GTIDs to make binlog replication simpler and easier to troubleshoot.

MySQL uses two different types of transactions for binlog replication:

- *GTID transactions* – Transactions that are identified by a GTID.
- *Anonymous transactions* – Transactions that don't have a GTID assigned.

In a replication configuration, GTIDs are unique across all DB instances. GTIDs simplify replication configuration because when you use them, you don't have to refer to log file positions. GTIDs also make it easier to track replicated transactions and determine whether the source instance and replicas are consistent.

You can use GTID-based replication to replicate data with Amazon RDS MySQL read replicas or with an external MySQL database. For RDS for MySQL read replicas, you can configure GTID-based replication when you are creating new read replicas, or you can convert existing read replicas to use GTID-based replication.

You can also use GTID-based replication in a delayed replication configuration with RDS for MySQL . For more information, see [Configuring delayed replication with MySQL \(p. 905\)](#).

Parameters for GTID-based replication

Use the following parameters to configure GTID-based replication.

Parameter	Valid values	Description
gtid_mode	OFF, OFF_PERMISSIVE, ON_PERMISSIVE, ON	<p>OFF specifies that new transactions are anonymous transactions (that is, don't have GTIDs), and a transaction must be anonymous to be replicated.</p> <p>OFF_PERMISSIVE specifies that new transactions are anonymous transactions, but all transactions can be replicated.</p> <p>ON_PERMISSIVE specifies that new transactions are GTID transactions, but all transactions can be replicated.</p> <p>ON specifies that new transactions are GTID transactions, and a transaction must be a GTID transaction to be replicated.</p>
enforce_gtid_consistency	OFF, ON, WARN	<p>OFF allows transactions to violate GTID consistency.</p> <p>ON prevents transactions from violating GTID consistency.</p> <p>WARN allows transactions to violate GTID consistency but generates a warning when a violation occurs.</p>

Note

In the AWS Management Console, the `gtid_mode` parameter appears as `gtid-mode`.

For GTID-based replication, use these settings for the parameter group for your DB instance or read replica:

- ON and ON_PERMISSIVE apply only to outgoing replication from an RDS DB instance or Aurora MySQL cluster. Both of these values cause your RDS DB instance or Aurora DB cluster to use GTIDs for transactions that are replicated to an external database. ON requires that the external database also use GTID-based replication. ON_PERMISSIVE makes GTID-based replication optional on the external database.
- OFF_PERMISSIVE, if set, means that your RDS DB instances or Aurora DB cluster can accept incoming replication from an external database. It can do this whether the external database uses GTID-based replication or not.
- OFF, if set, means that your RDS DB instances or Aurora DB cluster only accept incoming replication from external databases that don't use GTID-based replication.

For more information about parameter groups, see [Working with DB parameter groups \(p. 228\)](#).

Configuring GTID-based replication for new read replicas

When GTID-based replication is enabled for an RDS for MySQL DB instance, GTID-based replication is configured automatically for read replicas of the DB instance.

To enable GTID-based replication for new read replicas

1. Make sure that the parameter group associated with the DB instance has the following parameter settings:

- `gtid_mode` – ON or ON_PERMISSIVE
- `enforce_gtid_consistency` – ON

For more information about setting configuration parameters using parameter groups, see [Working with DB parameter groups \(p. 228\)](#).

2. If you changed the parameter group of the DB instance, reboot the DB instance. For more information on how to do so, see [Rebooting a DB instance \(p. 276\)](#).
3. Create one or more read replicas of the DB instance. For more information on how to do so, see [Creating a read replica \(p. 283\)](#).

Amazon RDS attempts to establish GTID-based replication between the MySQL DB instance and the read replicas using the `MASTER_AUTO_POSITION`. If the attempt fails, Amazon RDS uses log file positions for replication with the read replicas. For more information about the `MASTER_AUTO_POSITION`, see [GTID auto-positioning](#) in the MySQL documentation.

Configuring GTID-based replication for existing read replicas

For an existing MySQL DB instance with read replicas that doesn't use GTID-based replication, you can configure GTID-based replication between the DB instance and the read replicas.

To enable GTID-based replication for existing read replicas

1. If the DB instance or any read replica is using RDS for MySQL version 5.7.22 or lower, upgrade the DB instance or read replica. Upgrade to RDS for MySQL version 5.7.23 or a later MySQL 5.7 version.

For more information, see [Upgrading the MySQL DB engine \(p. 853\)](#).

2. (Optional) Reset the GTID parameters and test the behavior of the DB instance and read replicas:

- a. Make sure that the parameter group associated with the DB instance and each read replica has the `enforce_gtid_consistency` parameter set to `WARN`.

For more information about setting configuration parameters using parameter groups, see [Working with DB parameter groups \(p. 228\)](#).

- b. If you changed the parameter group of the DB instance, reboot the DB instance. If you changed the parameter group for a read replica, reboot the read replica.

For more information, see [Rebooting a DB instance \(p. 276\)](#).

- c. Run your DB instance and read replicas with your normal workload and monitor the log files.

If you see warnings about GTID-incompatible transactions, adjust your application so that it only uses GTID-compatible features. Make sure that the DB instance is not generating any warnings about GTID-incompatible transactions before proceeding to the next step.

3. Reset the GTID parameters for GTID-based replication that allows anonymous transactions until the read replicas have processed all of them.

- a. Make sure that the parameter group associated with the DB instance and each read replica has the following parameter settings:

- `gtid_mode` – ON_PERMISSIVE
- `enforce_gtid_consistency` – ON

- b. If you changed the parameter group of the DB instance, reboot the DB instance. If you changed the parameter group for a read replica, reboot the read replica.

4. Wait for all of your anonymous transactions to be replicated. To check that these are replicated, do the following:

- a. Run the following statement on your source DB instance.

```
SHOW MASTER STATUS;
```

Note the values in the `File` and `Position` columns.

- b. On each read replica, use the file and position information from its source instance in the previous step to run the following query.

```
SELECT MASTER_POS_WAIT('file', position);
```

For example, if the file name is `mysql-bin-changelog.000031` and the position is `107`, run the following statement.

```
SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);
```

If the read replica is past the specified position, the query returns immediately. Otherwise, the function waits. Proceed to the next step when the query returns for all read replicas.

5. Reset the GTID parameters for GTID-based replication only.

- a. Make sure that the parameter group associated with the DB instance and each read replica has the following parameter settings:

- `gtid_mode` – ON
- `enforce_gtid_consistency` – ON

- b. Reboot the DB instance and each read replica.

6. On each read replica, run the following procedure.

```
CALL mysql.rds_set_master_auto_position(1);
```

Disabling GTID-based replication for a MySQL DB instance with read replicas

You can disable GTID-based replication for a MySQL DB instance with read replicas.

To disable GTID-based replication for a MySQL DB instance with read replicas

1. On each read replica, run the following procedure.

```
CALL mysql.rds_set_master_auto_position(0);
```

2. Reset the `gtid_mode` to `ON_PERMISSIVE`.

- a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has `gtid_mode` set to `ON_PERMISSIVE`.

For more information about setting configuration parameters using parameter groups, see [Working with DB parameter groups \(p. 228\)](#).

- b. Reboot the MySQL DB instance and each read replica. For more information about rebooting, see [Rebooting a DB instance \(p. 276\)](#).

3. Reset the `gtid_mode` to `OFF_PERMISSIVE`:

- a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has `gtid_mode` set to `OFF_PERMISSIVE`.
 - b. Reboot the MySQL DB instance and each read replica.
4. Wait for all of the GTID transactions to be applied on all of the read replicas. To check that these are applied, do the following:
- Wait for all of the GTID transactions to be applied on the Aurora primary instance. To check that these are applied, do the following:
- a. On the MySQL DB instance, run the `SHOW MASTER STATUS` command.

Your output should be similar to the following.

File	Position
mysql-bin-changelog.000031	107

Note the file and position in your output.

- b. On each read replica, use the file and position information from its source instance in the previous step to run the following query.

```
SELECT MASTER_POS_WAIT('file', position);
```

For example, if the file name is `mysql-bin-changelog.000031` and the position is `107`, run the following statement.

```
SELECT MASTER_POS_WAIT('mysql-bin-changelog.000031', 107);
```

If the read replica is past the specified position, the query returns immediately. Otherwise, the function waits. When the query returns for all read replicas, go to the next step.

5. Reset the GTID parameters to disable GTID-based replication:
- a. Make sure that the parameter group associated with the MySQL DB instance and each read replica has the following parameter settings:
 - `gtid_mode` – OFF
 - `enforce_gtid_consistency` – OFF
 - b. Reboot the MySQL DB instance and each read replica.

Replication with a MySQL or MariaDB instance running external to Amazon RDS

You can set up replication between an Amazon RDS for MySQL or MariaDB DB instance and a MySQL or MariaDB instance that is external to Amazon RDS.

Topics

- [Before you begin \(p. 915\)](#)
- [Configuring binary log file position replication with an external source instance \(p. 915\)](#)
- [Configuring GTID-based replication with an external source instance \(p. 918\)](#)

Before you begin

You can configure replication using the binary log file position of replicated transactions. On Amazon RDS MySQL 5.7.23 and later MySQL 5.7 versions, you can also configure replication using global transaction identifiers (GTIDs).

The permissions required to start replication on an Amazon RDS DB instance are restricted and not available to your Amazon RDS master user. Because of this, make sure that you use the Amazon RDS [mysql.rds_set_external_master \(p. 954\)](#) and [mysql.rds_start_replication \(p. 964\)](#) commands to set up replication between your live database and your Amazon RDS database.

To set the binary logging format for a MySQL or MariaDB database, update the `binlog_format` parameter. If your DB instance uses the default DB instance parameter group, create a new DB parameter group to modify `binlog_format` settings. We recommend that you use the default setting for `binlog_format`, which is `MIXED`. However, you can also set `binlog_format` to `ROW` or `STATEMENT` if you need a specific binlog format. Reboot your DB instance for the change to take effect.

For information about setting the `binlog_format` parameter, see [Setting the binary logging format \(p. 524\)](#). For information about the implications of different MySQL replication types, see [Advantages and disadvantages of statement-based and row-based replication](#) in the MySQL documentation.

Note

Use the procedure in this topic to configure replication in all cases except when the external instance is MariaDB version 10.0.2 or greater and the Amazon RDS instance is MariaDB.

In that case, use the procedure at [Configuring GTID-based replication into a MariaDB DB instance \(p. 613\)](#) to set up GTID-based replication.

Configuring binary log file position replication with an external source instance

Follow these guidelines when you set up an external source instance and a replica on Amazon RDS:

- Monitor failover events for the Amazon RDS DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see [Using Amazon RDS event notification \(p. 487\)](#).
- Maintain the binary logs (binlogs) on your source instance until you have verified that they have been applied to the replica. This maintenance makes sure that you can restore your source instance in the event of a failure.
- Turn on automated backups on your Amazon RDS DB instance. Turning on automated backups makes sure that you can restore your replica to a particular point in time if you need to re-synchronize your source instance and replica. For information on backups and point-in-time restore, see [Backing up and restoring an Amazon RDS DB instance \(p. 327\)](#).

To configure binary log file replication with an external source instance

1. Make the source MySQL or MariaDB instance read-only.

```
mysql> FLUSH TABLES WITH READ LOCK;
mysql> SET GLOBAL read_only = ON;
```

2. Run the `SHOW MASTER STATUS` command on the source MySQL or MariaDB instance to determine the binlog location.

You receive output similar to the following example.

File	Position
mysql-bin-changelog.000031	107

3. Copy the database from the external instance to the Amazon RDS DB instance using `mysqldump`. For very large databases, you might want to use the procedure in [Importing data to an Amazon RDS MySQL or MariaDB DB instance with reduced downtime \(p. 881\)](#).

For Linux, macOS, or Unix:

```
mysqldump --databases database_name \
    --single-transaction \
    --compress \
    --order-by-primary \
    -u local_user \
    -plocal_password | mysql \
        --host=hostname \
        --port=3306 \
        -u RDS_user_name \
        -pRDS_password
```

For Windows:

```
mysqldump --databases database_name ^
    --single-transaction ^
    --compress ^
    --order-by-primary ^
    -u local_user ^
    -plocal_password | mysql ^
        --host=hostname ^
        --port=3306 ^
        -u RDS_user_name ^
        -pRDS_password
```

Note

Make sure that there isn't a space between the `-p` option and the entered password.

To specify the host name, user name, port, and password to connect to your Amazon RDS DB instance, use the `--host`, `--user` (`-u`), `--port` and `-p` options in the `mysql` command. The host name is the Domain Name Service (DNS) name from the Amazon RDS DB instance endpoint, for example, `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the AWS Management Console.

4. Make the source MySQL or MariaDB instance writeable again.

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

For more information on making backups for use with replication, see [the MySQL documentation](#).

5. In the AWS Management Console, add the IP address of the server that hosts the external database to the VPC security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see [Security groups for your VPC](#) in the *Amazon Virtual Private Cloud User Guide*.

The IP address can change when the following conditions are met:

- You are using a public IP address for communication between the external source instance and the DB instance.

- The external source instance was stopped and restarted.

If these conditions are met, verify the IP address before adding it.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance. You do this so that your local network can communicate with your external MySQL or MariaDB instance. To find the IP address of the Amazon RDS DB instance, use the host command.

```
host db_instance_endpoint
```

The host name is the DNS name from the Amazon RDS DB instance endpoint.

6. Using the client of your choice, connect to the external instance and create a user to use for replication. Use this account solely for replication. and restrict it to your domain to improve security. The following is an example.

MySQL 5.5, 5.6, and 5.7

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

MySQL 8.0

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY  
'password';
```

7. For the external instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. For example, to grant the REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain, issue the following command.

MySQL 5.5, 5.6, and 5.7

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'  
IDENTIFIED BY 'password';
```

MySQL 8.0

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

8. Make the Amazon RDS DB instance the replica. To do so, first connect to the Amazon RDS DB instance as the master user. Then identify the external MySQL or MariaDB database as the source instance by using the [mysql.rds_set_external_master \(p. 954\)](#) command. Use the master log file name and master log position that you determined in step 2. The following is an example.

```
CALL mysql.rds_set_external_master ('mymasterserver.mydomain.com', 3306, 'repl_user',  
'password', 'mysql-bin-changelog.000031', 107, 0);
```

Note

On Amazon RDS for MySQL, you can choose to use delayed replication by running the [mysql.rds_set_external_master_with_delay \(p. 956\)](#) stored procedure instead.

One reason to use delayed replication is to enable disaster recovery with the [mysql.rds_start_replication_until \(p. 965\)](#) stored procedure. Currently, delayed replication is not supported on RDS for MariaDB.

9. On the Amazon RDS DB instance, issue the [mysql.rds_start_replication \(p. 964\)](#) command to start replication:

```
CALL mysql.rds_start_replication;
```

Configuring GTID-based replication with an external source instance

When you set up an external source instance and a replica on Amazon RDS, monitor failover events for the Amazon RDS DB instance that is your replica. If a failover occurs, then the DB instance that is your replica might be recreated on a new host with a different network address. For information on how to monitor failover events, see [Using Amazon RDS event notification \(p. 487\)](#).

Important

GTID-based replication is only supported on Amazon RDS for MySQL version 5.7.23 and later MySQL 5.7 versions. GTID-based replication is not supported for Amazon RDS for MySQL 5.5, 5.6, or 8.0.

To configure GTID-based replication with an external source instance

1. Prepare for GTID-based replication:

- a. Make sure that the external MySQL or MariaDB database has GTID-based replication enabled. To do so, make sure that the external database has the following parameters set to the specified values:

```
gtid_mode - ON  
enforce_gtid_consistency - ON
```

For more information, see [Replication with global transaction identifiers](#) in the MySQL documentation or [Global transaction ID](#) in the MariaDB documentation.

- b. Make sure that the parameter group associated with the DB instance has the following parameter settings:

- `gtid_mode` – ON, ON_PERMISSIVE, or OFF_PERMISSIVE
- `enforce_gtid_consistency` – ON

For more information about parameter groups, see [Working with DB parameter groups \(p. 228\)](#).

- c. If you changed the parameter group of the DB instance, reboot the DB instance. For more information, see [Rebooting a DB instance \(p. 276\)](#).

2. Make the source MySQL or MariaDB instance read-only.

```
mysql> FLUSH TABLES WITH READ LOCK;  
mysql> SET GLOBAL read_only = ON;
```

3. Copy the database from the external instance to the Amazon RDS DB instance using `mysqldump`. For very large databases, you might want to use the procedure in [Importing data to an Amazon RDS MySQL or MariaDB DB instance with reduced downtime \(p. 881\)](#).

For Linux, macOS, or Unix:

```
mysqldump --databases database_name \  
--single-transaction \  
--compress \  
--order-by-primary \  
-u local_user \  
-
```

```
-plocal_password | mysql \
--host=hostname \
--port=3306 \
-u RDS_user_name \
-pRDS_password
```

For Windows:

```
mysqldump --databases database_name ^
--single-transaction ^
--compress ^
--order-by-primary ^
-u local_user ^
-plocal_password | mysql ^
--host=hostname ^
--port=3306 ^
-u RDS_user_name ^
-pRDS_password
```

Note

Make sure that there is not a space between the `-p` option and the entered password.

To specify the host name, user name, port, and password to connect to your Amazon RDS DB instance, use the `--host`, `--user` (`-u`), `--port` and `-p` options in the `mysql` command. The host name is the DNS name from the Amazon RDS DB instance endpoint, for example, `myinstance.123456789012.us-east-1.rds.amazonaws.com`. You can find the endpoint value in the instance details in the AWS Management Console.

4. Make the source MySQL or MariaDB instance writeable again.

```
mysql> SET GLOBAL read_only = OFF;
mysql> UNLOCK TABLES;
```

For more information on making backups for use with replication, see [the MySQL documentation](#).

5. In the AWS Management Console, add the IP address of the server that hosts the external database to the VPC security group for the Amazon RDS DB instance. For more information on modifying a VPC security group, see [Security groups for your VPC](#) in the *Amazon Virtual Private Cloud User Guide*.

The IP address can change when the following conditions are met:

- You are using a public IP address for communication between the external source instance and the DB instance.
- The external source instance was stopped and restarted.

If these conditions are met, verify the IP address before adding it.

You might also need to configure your local network to permit connections from the IP address of your Amazon RDS DB instance. You do this so that your local network can communicate with your external MySQL or MariaDB instance. To find the IP address of the Amazon RDS DB instance, use the `host` command.

```
host db_instance_endpoint
```

The host name is the DNS name from the Amazon RDS DB instance endpoint.

6. Using the client of your choice, connect to the external instance and create a user to use for replication. Use this account solely for replication, and restrict it to your domain to improve security. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

7. For the external instance, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. For example, to grant the REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain, issue the following command.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'  
IDENTIFIED BY 'password';
```

8. Make the Amazon RDS DB instance the replica. To do so, first connect to the Amazon RDS DB instance as the master user. Then identify the external MySQL or MariaDB database as the replication primary instance by using the [mysql.rds_set_external_master_with_auto_position \(p. 959\)](#) command. The following is an example.

```
CALL mysql.rds_set_external_master_with_auto_position ('mymasterserver.mydomain.com',  
3306, 'repl_user', 'password', 0, 0);
```

Note

On Amazon RDS for MySQL, you can choose to use delayed replication by running the [mysql.rds_set_external_master_with_delay \(p. 956\)](#) stored procedure instead. One reason to use delayed replication is to enable disaster recovery with the [mysql.rds_start_replication_until_gtid \(p. 966\)](#) stored procedure. Currently, delayed replication is not supported on RDS for MariaDB.

9. On the Amazon RDS DB instance, issue the [mysql.rds_start_replication \(p. 964\)](#) command to start replication.

```
CALL mysql.rds_start_replication;
```

Exporting data from a MySQL DB instance by using replication

To export data from a MySQL 5.6 or later DB instance to a MySQL instance running external to Amazon RDS, you can use replication. In this scenario, the MySQL DB instance is the *source MySQL DB instance*, and the MySQL instance running external to Amazon RDS is the *external MySQL database*.

The source MySQL DB instance must be running version 5.6.13 or later. The external MySQL database can run either on-premises in your data center, or on an Amazon EC2 instance. The external MySQL database must run the same version as the source MySQL DB instance, or a later version.

Replication to an external MySQL database is only supported during the time it takes to export a database from the source MySQL DB instance. The replication should be terminated when the data has been exported and applications can start accessing the external MySQL instance.

The following list shows the steps to take. Each step is discussed in more detail in later sections.

1. Prepare an external MySQL DB instance.
2. Prepare the source MySQL DB instance for replication.
3. Use the mysqldump utility to transfer the database from the source MySQL DB instance to the external MySQL database.
4. Start replication to the external MySQL database.
5. After the export completes, stop replication.

Prepare an external MySQL database

Perform the following steps to prepare the external MySQL database.

To prepare the external MySQL database

1. Install the external MySQL database.
2. Connect to the external MySQL database as the master user. Then create the users required to support the administrators, applications, and services that access the database.
3. Follow the directions in the MySQL documentation to prepare the external MySQL database as a replica. For more information, see [the MySQL documentation](#).
4. Configure an egress rule for the external MySQL database to operate as a read replica during the export. The egress rule allows the external MySQL database to connect to the source MySQL DB instance during replication. Specify an egress rule that allows Transmission Control Protocol (TCP) connections to the port and IP address of the source MySQL DB instance.

Specify the appropriate egress rules for your environment:

- If the external MySQL database is running in an Amazon EC2 instance in a virtual private cloud (VPC) based on the Amazon VPC service, specify the egress rules in a VPC security group. For more information, see [Controlling access with security groups \(p. 1699\)](#).
 - If the external MySQL database is running in an Amazon EC2 instance that is not in a VPC, specify the egress rules in an EC2-Classic security group.
 - If the external MySQL database is installed on-premises, specify the egress rules in a firewall.
5. If the external MySQL database is running in a VPC, configure rules for the VPC access control list (ACL) rules in addition to the security group egress rule:
 - Configure an ACL ingress rule allowing TCP traffic to ports 1024–65535 from the IP address of the source MySQL DB instance.

- Configure an ACL egress rule allowing outbound TCP traffic to the port and IP address of the source MySQL DB instance.

For more information about Amazon VPC network ACLs, see [Network ACLs](#) in *Amazon VPC User Guide*.

6. (Optional) Set the `max_allowed_packet` parameter to the maximum size to avoid replication errors. We recommend this setting.

Prepare the source MySQL DB instance

Perform the following steps to prepare the source MySQL DB instance as the replication source.

To prepare the source MySQL DB instance

1. Ensure that your client computer has enough disk space available to save the binary logs while setting up replication.
2. Connect to the source MySQL DB instance, and create a replication account by following the directions in [Creating a user for replication](#) in the MySQL documentation.
3. Configure ingress rules on the system running the source MySQL DB instance to allow the external MySQL database to connect during replication. Specify an ingress rule that allows TCP connections to the port used by the source MySQL DB instance from the IP address of the external MySQL database.
4. Specify the egress rules:
 - If the source MySQL DB instance is running in a VPC, specify the ingress rules in a VPC security group. For more information, see [Controlling access with security groups \(p. 1699\)](#).
 - If the source MySQL DB instance isn't running in a VPC, specify the ingress rules in a DB security group. For more information, see [Authorizing network access to a DB security group from an IP range \(p. 1708\)](#).
5. If source MySQL DB instance is running in a VPC, configure VPC ACL rules in addition to the security group ingress rule:
 - Configure an ACL ingress rule to allow TCP connections to the port used by the Amazon RDS instance from the IP address of the external MySQL database.
 - Configure an ACL egress rule to allow TCP connections from ports 1024–65535 to the IP address of the external MySQL database.

For more information about Amazon VPC network ACLs, see [Network ACLs](#) in the *Amazon VPC User Guide*.

6. Ensure that the backup retention period is set long enough that no binary logs are purged during the export. If any of the logs are purged before the export has completed, you must restart replication from the beginning. For more information about setting the backup retention period, see [Working with backups \(p. 328\)](#).
7. Use the `mysql.rds_set_configuration` stored procedure to set the binary log retention period long enough that the binary logs aren't purged during the export. For more information, see [Accessing MySQL binary logs \(p. 525\)](#).
8. Create an Amazon RDS read replica from the source MySQL DB instance to further ensure that the binary logs of the source MySQL DB instance are not purged. For more information, see [Creating a read replica \(p. 283\)](#).
9. After the Amazon RDS read replica has been created, call the `mysql.rds_stop_replication` stored procedure to stop the replication process. The source MySQL DB instance no longer purges its binary log files, so they are available for the replication process.

10. (Optional) Set both the `max_allowed_packet` parameter and the `slave_max_allowed_packet` parameter to the maximum size to avoid replication errors. The maximum size for both parameters is 1 GB. We recommend this setting for both parameters. For information about setting parameters, see [Modifying parameters in a DB parameter group \(p. 232\)](#).

Copy the database

Perform the following steps to copy the database.

To copy the database

1. Connect to the RDS read replica of the source MySQL DB instance, and run the MySQL `SHOW SLAVE STATUS\G` statement. Note the values for the following:
 - `Master_Host`
 - `Master_Port`
 - `Master_Log_File`
 - `Exec_Master_Log_Pos`
2. Use the `mysqldump` utility to create a snapshot, which copies the data from Amazon RDS to your local client computer. Then run another utility to load the data into the external MySQL database. Ensure that your client computer has enough space to hold the `mysqldump` files from the databases to be replicated. This process can take several hours for very large databases. Follow the directions in [Creating a data snapshot using mysqldump](#) in the MySQL documentation.

The following example runs `mysqldump` on a client, and then pipes the dump into the `mysql` client utility, which loads the data into the external MySQL database.

For Linux, macOS, or Unix:

```
mysqldump -h source_MySQL_DB_instance_endpoint \
-u user \
-ppassword \
--port=3306 \
--single-transaction \
--routines \
--triggers \
--databases database database2 \
--compress \
--port 3306
```

For Windows:

```
mysqldump -h source_MySQL_DB_instance_endpoint ^
-u user ^
-ppassword ^
--port=3306 ^
--single-transaction ^
--routines ^
--triggers ^
--databases database database2 ^
--compress ^
--port 3306
```

The following example runs `mysqldump` on a client and writes the dump to a file.

For Linux, macOS, or Unix:

```
mysqldump -h source_MySQL_DB_instance_endpoint \
-u user \
-ppassword \
--port=3306 \
--single-transaction \
--routines \
--triggers \
--databases database database2 > path/rds-dump.sql
```

For Windows:

```
mysqldump -h source_MySQL_DB_instance_endpoint ^
-u user ^
-ppassword ^
--port=3306 ^
--single-transaction ^
--routines ^
--triggers ^
--databases database database2 > path\rds-dump.sql
```

Complete the export

Perform the following steps to complete the export.

To complete the export

1. Load the mysqldump files to create the databases on the external MySQL database.
2. On the Amazon RDS read replica, call the `mysql.rds_start_replication` stored procedure. Doing this starts replication from the source MySQL DB instance and exports all source changes that have occurred after you stopped replication from the Amazon RDS read replica.
3. Use the MySQL `CHANGE MASTER` statement to configure the external MySQL database. Specify the ID and password of the user granted `REPLICATION SLAVE` permissions. Specify the `Master_Host`, `Master_Port`, `Relay_Master_Log_File`, and `Exec_Master_Log_Pos` values that you got from the MySQL `SHOW SLAVE STATUS\G` statement that you ran on the RDS read replica. For more information, see [the MySQL documentation](#).
4. Use the MySQL `START SLAVE` command to initiate replication from the source MySQL DB instance to the external MySQL database.
5. Run the MySQL `SHOW SLAVE STATUS\G` command on the external MySQL database to verify that it is operating as a read replica. For more information about interpreting the results, see [the MySQL documentation](#).
6. After replication on the external MySQL database has caught up with the source MySQL DB instance, use the MySQL `STOP SLAVE` command to stop replication from the source MySQL DB instance.
7. On the Amazon RDS read replica, call the `mysql.rds_start_replication` stored procedure. Doing this allows Amazon RDS to start purging the binary log files from the source MySQL DB instance.

Options for MySQL DB instances

This appendix describes options, or additional features, that are available for Amazon RDS instances running the MySQL DB engine. To enable these options, you can add them to a custom option group, and then associate the option group with your DB instance. For more information about working with option groups, see [Working with option groups \(p. 212\)](#).

Amazon RDS supports the following options for MySQL:

Option	Option ID	Engine versions
MariaDB Audit Plugin support (p. 926)	MARIADB_AUDIT_PLUGIN	All MySQL 5.6 versions
		MySQL 5.7.16 and later 5.7 versions
MySQL memcached support (p. 929)	MEMCACHED	All MySQL 5.6, 5.7, and 8.0 versions

MariaDB Audit Plugin support

Amazon RDS supports using the MariaDB Audit Plugin on MySQL database instances. The MariaDB Audit Plugin records database activity such as users logging on to the database, queries run against the database, and more. The record of database activity is stored in a log file.

Note

Currently, the MariaDB Audit Plugin is only supported for the following RDS for MySQL versions:

- All 5.6 versions
 - MySQL 5.7.16 and later 5.7 versions

Audit Plugin option settings

Amazon RDS supports the following settings for the MariaDB Audit Plugin option.

Option setting	Valid values	Default value	Description
SERVER_AUDIT	/rdsdbdata/log/audit/	/rdsdbdata/log/audit/	The location of the log file. The log file contains the record of the activity specified in SERVER_AUDIT_EVENTS. For more information, see Viewing and listing database log files (p. 504) and Accessing MySQL database log files (p. 519) .
SERVER_AUDIT_SIZE	100000000	1000000	The size in bytes that when reached, causes the file to rotate. For more information, see Overview of MySQL database logs (p. 519) .
SERVER_AUDIT_ROTATIONS	100	9	The number of log rotations to save. For more information, see Overview of MySQL database logs (p. 519) and Downloading a database log file (p. 504) .
SERVER_AUDIT_EVENTS	CONNECT, QUERY, QUERY_DDL, QUERY_DML, QUERY_DCL	CONNECT, QUERY	<p>The types of activity to record in the log. Installing the MariaDB Audit Plugin is itself logged.</p> <ul style="list-style-type: none"> • CONNECT: Log successful and unsuccessful connections to the database, and disconnections from the database. • QUERY: Log the text of all queries run against the database. • QUERY_DDL: Similar to the QUERY event, but returns only data definition language (DDL) queries (CREATE, ALTER, and so on). • QUERY_DML: Similar to the QUERY event, but returns only data manipulation language (DML) queries (INSERT, UPDATE, and so on, and also SELECT). • QUERY_DCL: Similar to the QUERY event, but returns only data control language (DCL) queries (GRANT, REVOKE, and so on). <p>For MySQL, TABLE is not supported.</p>

Option setting	Valid values	Default value	Description
SERVER_AUDIT_USERS	Multiple comma-separated values	None	Include only activity from the specified users. By default, activity is recorded for all users. If a user is specified in both SERVER_AUDIT_EXCL_USERS and SERVER_AUDIT_INCL_USERS, then activity is recorded for the user.
SERVER_AUDIT_EXCL_USERS	Multiple comma-separated values	None	Exclude activity from the specified users. By default, activity is recorded for all users. If a user is specified in both SERVER_AUDIT_EXCL_USERS and SERVER_AUDIT_INCL_USERS, then activity is recorded for the user.
SERVER_AUDIT_LOGGING	ON	ON	The rdsadmin user queries the database every second to check the health of the database. Depending on your other settings, this activity can possibly cause the size of your log file to grow very large, very quickly. If you don't need to record this activity, add the rdsadmin user to the SERVER_AUDIT_EXCL_USERS list.
SERVER_AUDIT_QUERY_SIZE	002147483647M1024		The limit on the length of the query string in a record.

Adding the MariaDB Audit Plugin

The general process for adding the MariaDB Audit Plugin to a DB instance is the following:

- Create a new option group, or copy or modify an existing option group
- Add the option to the option group
- Associate the option group with the DB instance

After you add the MariaDB Audit Plugin, you don't need to restart your DB instance. As soon as the option group is active, auditing begins immediately.

Important

Adding the MariaDB Audit Plugin to a DB instance might cause an outage. We recommend adding the MariaDB Audit Plugin during a maintenance window or during a time of low database workload.

To add the MariaDB Audit Plugin

1. Determine the option group you want to use. You can create a new option group or use an existing option group. If you want to use an existing option group, skip to the next step. Otherwise, create a

- custom DB option group. Choose **mysql** for **Engine**, and choose **5.6** or **5.7** for **Major engine version**. For more information, see [Creating an option group \(p. 214\)](#).
2. Add the **MARIADB_AUDIT_PLUGIN** option to the option group, and configure the option settings. For more information about adding options, see [Adding an option to an option group \(p. 216\)](#). For more information about each setting, see [Audit Plugin option settings \(p. 926\)](#).
 3. Apply the option group to a new or existing DB instance.
 - For a new DB instance, you apply the option group when you launch the instance. For more information, see [Creating an Amazon RDS DB instance \(p. 141\)](#).
 - For an existing DB instance, you apply the option group by modifying the instance and attaching the new option group. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

Viewing and downloading the MariaDB Audit Plugin log

After you enable the MariaDB Audit Plugin, you access the results in the log files the same way you access any other text-based log files. The audit log files are located at `/rdsdbdata/log/audit/`. For information about viewing the log file in the console, see [Viewing and listing database log files \(p. 504\)](#). For information about downloading the log file, see [Downloading a database log file \(p. 504\)](#).

Modifying MariaDB Audit Plugin settings

After you enable the MariaDB Audit Plugin, you can modify the settings. For more information about how to modify option settings, see [Modifying an option setting \(p. 221\)](#). For more information about each setting, see [Audit Plugin option settings \(p. 926\)](#).

Removing the MariaDB Audit Plugin

Amazon RDS doesn't support turning off logging in the MariaDB Audit Plugin. However, you can remove the plugin from a DB instance. When you remove the MariaDB Audit Plugin, the DB instance is restarted automatically to stop auditing.

To remove the MariaDB Audit Plugin from a DB instance, do one of the following:

- Remove the MariaDB Audit Plugin option from the option group it belongs to. This change affects all DB instances that use the option group. For more information, see [Removing an option from an option group \(p. 224\)](#).
- Modify the DB instance and specify a different option group that doesn't include the plugin. This change affects a single DB instance. You can specify the default (empty) option group, or a different custom option group. For more information, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

MySQL memcached support

Amazon RDS supports using the memcached interface to InnoDB tables that was introduced in MySQL 5.6. The memcached API enables applications to use InnoDB tables in a manner similar to NoSQL key-value data stores.

The memcached interface is a simple, key-based cache. Applications use memcached to insert, manipulate, and retrieve key-value data pairs from the cache. MySQL 5.6 introduced a plugin that implements a daemon service that exposes data from InnoDB tables through the memcached protocol. For more information about the MySQL memcached plugin, see [InnoDB integration with memcached](#).

To enable memcached support for an RDS for MySQL 5.6 or later instance

1. Determine the security group to use for controlling access to the memcached interface. If the set of applications already using the SQL interface are the same set that will access the memcached interface, you can use the existing VPC or DB security group used by the SQL interface. If a different set of applications will access the memcached interface, define a new VPC or DB security group. For more information about managing security groups, see [Controlling access with security groups \(p. 1699\)](#)
2. Create a custom DB option group, selecting MySQL as the engine type and a 5.6 or later version. For more information about creating an option group, see [Creating an option group \(p. 214\)](#).
3. Add the MEMCACHED option to the option group. Specify the port that the memcached interface will use, and the security group to use in controlling access to the interface. For more information about adding options, see [Adding an option to an option group \(p. 216\)](#).
4. Modify the option settings to configure the memcached parameters, if necessary. For more information about how to modify option settings, see [Modifying an option setting \(p. 221\)](#).
5. Apply the option group to an instance. Amazon RDS enables memcached support for that instance when the option group is applied:
 - You enable memcached support for a new instance by specifying the custom option group when you launch the instance. For more information about launching a MySQL instance, see [Creating an Amazon RDS DB instance \(p. 141\)](#).
 - You enable memcached support for an existing instance by specifying the custom option group when you modify the instance. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).
6. Specify which columns in your MySQL tables can be accessed through the memcached interface. The memcached plug-in creates a catalog table named `containers` in a dedicated database named `innodb_memcache`. You insert a row into the `containers` table to map an InnoDB table for access through memcached. You specify a column in the InnoDB table that is used to store the memcached key values, and one or more columns that are used to store the data values associated with the key. You also specify a name that a memcached application uses to refer to that set of columns. For details on inserting rows in the `containers` table, see [InnoDB memcached plugin internals](#). For an example of mapping an InnoDB table and accessing it through memcached, see [Writing applications for the InnoDB memcached plugin](#).
7. If the applications accessing the memcached interface are on different computers or EC2 instances than the applications using the SQL interface, add the connection information for those computers to the VPC or DB security group associated with the MySQL instance. For more information about managing security groups, see [Controlling access with security groups \(p. 1699\)](#).

You turn off the memcached support for an instance by modifying the instance and specifying the default option group for your MySQL version. For more information about modifying a DB instance, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

MySQL memcached security considerations

The memcached protocol does not support user authentication. For more information about MySQL memcached security considerations, see [memcached deployment](#) and [Using memcached as a MySQL caching layer](#).

You can take the following actions to help increase the security of the memcached interface:

- Specify a different port than the default of 11211 when adding the **MEMCACHED** option to the option group.
- Ensure that you associate the memcached interface with either a VPC or DB security group that limits access to known, trusted client addresses or EC2 instances. For more information about managing security groups, see [Controlling access with security groups \(p. 1699\)](#).

MySQL memcached connection information

To access the memcached interface, an application must specify both the DNS name of the Amazon RDS instance and the memcached port number. For example, if an instance has a DNS name of `my-cache-instance.cg034hpkmmt.region.rds.amazonaws.com` and the memcached interface is using port 11212, the connection information specified in PHP would be:

```
<?php  
  
$cache = new Memcache;  
$cache->connect('my-cache-instance.cg034hpkmmt.region.rds.amazonaws.com', 11212);  
?>
```

To find the DNS name and memcached port of a MySQL DB instance

1. Sign in to the AWS Management Console and open the Amazon RDS console at <https://console.aws.amazon.com/rds/>.
2. In the top right corner of the AWS Management Console, select the region that contains the DB instance.
3. In the navigation pane, choose **Databases**.
4. Choose the MySQL DB instance name to display its details.
5. In the **Connect** section, note the value of the **Endpoint** field. The DNS name is the same as the endpoint. Also, note that the port in the **Connect** section is not used to access the memcached interface.
6. In the **Details** section, note the name listed in the **Option Group** field.
7. In the navigation pane, choose **Option groups**.
8. Choose the name of the option group used by the MySQL DB instance to show the option group details. In the **Options** section, note the value of the **Port** setting for the **MEMCACHED** option.

MySQL memcached option settings

Amazon RDS exposes the MySQL memcached parameters as option settings in the Amazon RDS **MEMCACHED** option.

MySQL memcached parameters

- **DAEMON_MEMCACHED_R_BATCH_SIZE** – an integer that specifies how many memcached read operations (get) to perform before doing a COMMIT to start a new transaction. The allowed values are 1 to 4294967295; the default is 1. The option does not take effect until the instance is restarted.

- **DAEMON_MEMCACHED_W_BATCH_SIZE** – an integer that specifies how many memcached write operations, such as add, set, or incr, to perform before doing a COMMIT to start a new transaction. The allowed values are 1 to 4294967295; the default is 1. The option does not take effect until the instance is restarted.
- **INNODB_API_BK_COMMIT_INTERVAL** – an integer that specifies how often to auto-commit idle connections that use the InnoDB memcached interface. The allowed values are 1 to 1073741824; the default is 5. The option takes effect immediately, without requiring that you restart the instance.
- **INNODB_API_DISABLE_ROWLOCK** – a Boolean that disables (1 (true)) or enables (0 (false)) the use of row locks when using the InnoDB memcached interface. The default is 0 (false). The option does not take effect until the instance is restarted.
- **INNODB_API_ENABLE_MDL** – a Boolean that when set to 0 (false) locks the table used by the InnoDB memcached plugin, so that it cannot be dropped or altered by DDL through the SQL interface. The default is 0 (false). The option does not take effect until the instance is restarted.
- **INNODB_API_TRX_LEVEL** – an integer that specifies the transaction isolation level for queries processed by the memcached interface. The allowed values are 0 to 3. The default is 0. The option does not take effect until the instance is restarted.

Amazon RDS configures these MySQL memcached parameters, and they cannot be modified: DAEMON_MEMCACHED_LIB_NAME, DAEMON_MEMCACHED_LIB_PATH, and INNODB_API_ENABLE_BINLOG. The parameters that MySQL administrators set by using `daemon_memcached_options` are available as individual MEMCACHED option settings in Amazon RDS.

MySQL `daemon_memcached_options` parameters

- **BINDING_PROTOCOL** – a string that specifies the binding protocol to use. The allowed values are auto, ascii, or binary. The default is auto, which means the server automatically negotiates the protocol with the client. The option does not take effect until the instance is restarted.
- **BACKLOG_QUEUE_LIMIT** – an integer that specifies how many network connections can be waiting to be processed by memcached. Increasing this limit may reduce errors received by a client that is not able to connect to the memcached instance, but does not improve the performance of the server. The allowed values are 1 to 2048; the default is 1024. The option does not take effect until the instance is restarted.
- **CAS_DISABLED** – a Boolean that enables (1 (true)) or disables (0 (false)) the use of compare and swap (CAS), which reduces the per-item size by 8 bytes. The default is 0 (false). The option does not take effect until the instance is restarted.
- **CHUNK_SIZE** – an integer that specifies the minimum chunk size, in bytes, to allocate for the smallest item's key, value, and flags. The allowed values are 1 to 48. The default is 48 and you can significantly improve memory efficiency with a lower value. The option does not take effect until the instance is restarted.
- **CHUNK_SIZE_GROWTH_FACTOR** – a float that controls the size of new chunks. The size of a new chunk is the size of the previous chunk times CHUNK_SIZE_GROWTH_FACTOR. The allowed values are 1 to 2; the default is 1.25. The option does not take effect until the instance is restarted.
- **ERROR_ON_MEMORY_EXHAUSTED** – a Boolean that when set to 1 (true) specifies that memcached will return an error rather than evicting items when there is no more memory to store items. If set to 0 (false), memcached will evict items if there is no more memory. The default is 0 (false). The option does not take effect until the instance is restarted.
- **MAX_SIMULTANEOUS_CONNECTIONS** – an integer that specifies the maximum number of concurrent connections. Setting this value to anything under 10 prevents MySQL from starting. The allowed values are 10 to 1024; the default is 1024. The option does not take effect until the instance is restarted.
- **VERBOSITY** – a string that specifies the level of information logged in the MySQL error log by the memcached service. The default is v. The option does not take effect until the instance is restarted. The allowed values are:

- **v** – Logs errors and warnings while running the main event loop.
- **vv** – In addition to the information logged by v, also logs each client command and the response.
- **vvv** – In addition to the information logged by vv, also logs internal state transitions.

Amazon RDS configures these MySQL DAEMON_MEMCACHED_OPTIONS parameters, they cannot be modified: DAEMON_PROCESS, LARGE_MEMORY_PAGES, MAXIMUM_CORE_FILE_LIMIT, MAX_ITEM_SIZE, LOCK_DOWN_PAGE_MEMORY, MASK, IDFILE, REQUESTS_PER_EVENT, SOCKET, and USER.

Common DBA tasks for MySQL DB instances

This section describes the Amazon RDS-specific implementations of some common DBA tasks for DB instances running the MySQL database engine. In order to deliver a managed service experience, Amazon RDS does not provide shell access to DB instances, and it restricts access to certain system procedures and tables that require advanced privileges.

For information about working with MySQL log files on Amazon RDS, see [Accessing MySQL database log files \(p. 519\)](#).

Topics

- [Ending a session or query \(p. 933\)](#)
- [Skipping the current replication error \(p. 933\)](#)
- [Working with InnoDB tablespaces to improve crash recovery times \(p. 934\)](#)
- [Managing the global status history \(p. 936\)](#)

Ending a session or query

You can end user sessions or queries on DB instances by using the `rds_kill` and `rds_kill_query` commands. First connect to your MySQL DB instance, then issue the appropriate command as shown following. For more information, see [Connecting to a DB instance running the MySQL database engine \(p. 840\)](#).

```
CALL mysql.rds_kill(thread-ID)
CALL mysql.rds_kill_query(thread-ID)
```

For example, to end the session that is running on thread 99, you would type the following:

```
CALL mysql.rds_kill(99);
```

To end the query that is running on thread 99, you would type the following:

```
CALL mysql.rds_kill_query(99);
```

Skipping the current replication error

Amazon RDS provides a mechanism for you to skip an error on your read replicas if the error is causing your read replica to stop responding and the error doesn't affect the integrity of your data. First connect to your MySQL DB instance, then issue the appropriate commands as shown following. For more information, see [Connecting to a DB instance running the MySQL database engine \(p. 840\)](#).

Note

You should first verify that the error can be safely skipped. In a MySQL utility, connect to the read replica and run the following MySQL command:

```
SHOW SLAVE STATUS\G
```

For information about the values returned, see [the MySQL documentation](#).

To skip the error, you can issue the following command:

```
CALL mysql.rds_skip_repl_error;
```

This command has no effect if you run it on the source DB instance, or on a read replica that has not encountered a replication error.

For more information, such as the versions of MySQL that support `mysql.rds_skip_repl_error`, see [mysql.rds_skip_repl_error \(p. 968\)](#).

Important

If you attempt to call `mysql.rds_skip_repl_error` and encounter the following error: `ERROR 1305 (42000): PROCEDURE mysql.rds_skip_repl_error does not exist`, then upgrade your MySQL DB instance to the latest minor version or one of the minimum minor versions listed in [mysql.rds_skip_repl_error \(p. 968\)](#).

Working with InnoDB tablespaces to improve crash recovery times

Every table in MySQL consists of a table definition, data, and indexes. The MySQL storage engine InnoDB stores table data and indexes in a *tablespace*. InnoDB creates a global shared tablespace that contains a data dictionary and other relevant metadata, and it can contain table data and indexes. InnoDB can also create separate tablespaces for each table and partition. These separate tablespaces are stored in files with a .ibd extension and the header of each tablespace contains a number that uniquely identifies it.

Amazon RDS provides a parameter in a MySQL parameter group called `innodb_file_per_table`. This parameter controls whether InnoDB adds new table data and indexes to the shared tablespace (by setting the parameter value to 0) or to individual tablespaces (by setting the parameter value to 1). Amazon RDS sets the default value for `innodb_file_per_table` parameter to 1, which allows you to drop individual InnoDB tables and reclaim storage used by those tables for the DB instance. In most use cases, setting the `innodb_file_per_table` parameter to 1 is the recommended setting.

You should set the `innodb_file_per_table` parameter to 0 when you have a large number of tables, such as over 1000 tables when you use standard (magnetic) or general purpose SSD storage or over 10,000 tables when you use Provisioned IOPS storage. When you set this parameter to 0, individual tablespaces are not created and this can improve the time it takes for database crash recovery.

MySQL processes each metadata file, which includes tablespaces, during the crash recovery cycle. The time it takes MySQL to process the metadata information in the shared tablespace is negligible compared to the time it takes to process thousands of tablespace files when there are multiple tablespaces. Because the tablespace number is stored within the header of each file, the aggregate time to read all the tablespace files can take up to several hours. For example, a million InnoDB tablespaces on standard storage can take from five to eight hours to process during a crash recovery cycle. In some cases, InnoDB can determine that it needs additional cleanup after a crash recovery cycle so it will begin another crash recovery cycle, which will extend the recovery time. Keep in mind that a crash recovery cycle also entails rolling-back transactions, fixing broken pages, and other operations in addition to the processing of tablespace information.

Since the `innodb_file_per_table` parameter resides in a parameter group, you can change the parameter value by editing the parameter group used by your DB instance without having to reboot the DB instance. After the setting is changed, for example, from 1 (create individual tables) to 0 (use shared tablespace), new InnoDB tables will be added to the shared tablespace while existing tables continue to have individual tablespaces. To move an InnoDB table to the shared tablespace, you must use the `ALTER TABLE` command.

Migrating multiple tablespaces to the shared tablespace

You can move an InnoDB table's metadata from its own tablespace to the shared tablespace, which will rebuild the table metadata according to the `innodb_file_per_table` parameter setting. First connect to your MySQL DB instance, then issue the appropriate commands as shown following. For more information, see [Connecting to a DB instance running the MySQL database engine \(p. 840\)](#).

```
ALTER TABLE table_name ENGINE = InnoDB, ALGORITHM=COPY;
```

For example, the following query returns an `ALTER TABLE` statement for every InnoDB table that is not in the shared tablespace.

For MySQL 5.6 and 5.7 DB instances:

```
SELECT CONCAT('ALTER TABLE `',
REPLACE(LEFT(NAME , INSTR((NAME), '/') - 1), '``', '```'), '``.`',
REPLACE(SUBSTR(NAME FROM INSTR(NAME, '/') + 1), '``', '```'), '``' ENGINE=InnoDB,
ALGORITHM=COPY;') AS Query
FROM INFORMATION_SCHEMA.INNODB_SYS_TABLES
WHERE SPACE <> 0 AND LEFT(NAME, INSTR((NAME), '/') - 1) NOT IN ('mysql','');
```

For MySQL 8.0 DB instances:

```
SELECT CONCAT('ALTER TABLE `',
REPLACE(LEFT(NAME , INSTR((NAME), '/') - 1), '``', '```'), '``.`',
REPLACE(SUBSTR(NAME FROM INSTR(NAME, '/') + 1), '``', '```'), '``' ENGINE=InnoDB,
ALGORITHM=COPY;') AS Query
FROM INFORMATION_SCHEMA.INNODB_TABLES
WHERE SPACE <> 0 AND LEFT(NAME, INSTR((NAME), '/') - 1) NOT IN ('mysql','');
```

Rebuilding a MySQL table to move the table's metadata to the shared tablespace requires additional storage space temporarily to rebuild the table, so the DB instance must have storage space available. During rebuilding, the table is locked and inaccessible to queries. For small tables or tables not frequently accessed, this might not be an issue. For large tables or tables frequently accessed in a heavily concurrent environment, you can rebuild tables on a read replica.

You can create a read replica and migrate table metadata to the shared tablespace on the read replica. While the `ALTER TABLE` statement blocks access on the read replica, the source DB instance is not affected. The source DB instance will continue to generate its binary logs while the read replica lags during the table rebuilding process. Because the rebuilding requires additional storage space and the replay log file can become large, you should create a read replica with storage allocated that is larger than the source DB instance.

To create a read replica and rebuild InnoDB tables to use the shared tablespace, take the following steps:

1. Make sure that backup retention is enabled on the source DB instance so that binary logging is enabled.
2. Use the AWS Management Console or AWS CLI to create a read replica for the source DB instance. Because the creation of a read replica involves many of the same processes as crash recovery, the creation process can take some time if there is a large number of InnoDB tablespaces. Allocate more storage space on the read replica than is currently used on the source DB instance.
3. When the read replica has been created, create a parameter group with the parameter settings `read_only = 0` and `innodb_file_per_table = 0`. Then associate the parameter group with the read replica.
4. Issue the following SQL statement for all tables that you want migrated on the replica:

```
ALTER TABLE name ENGINE = InnoDB
```

5. When all of your `ALTER TABLE` statements have completed on the read replica, verify that the read replica is connected to the source DB instance and that the two instances are in sync.
6. Use the console or CLI to promote the read replica to be the instance. Make sure that the parameter group used for the new standalone DB instance has the `innodb_file_per_table` parameter set to 0. Change the name of the new standalone DB instance, and point any applications to the new standalone DB instance.

Managing the global status history

MySQL maintains many status variables that provide information about its operation. Their value can help you detect locking or memory issues on a DB instance . The values of these status variables are cumulative since last time the DB instance was started. You can reset most status variables to 0 by using the `FLUSH STATUS` command.

To allow for monitoring of these values over time, Amazon RDS provides a set of procedures that will snapshot the values of these status variables over time and write them to a table, along with any changes since the last snapshot. This infrastructure, called Global Status History (GoSH), is installed on all MySQL DB instances starting with versions 5.5.23. GoSH is disabled by default.

To enable GoSH, you first enable the event scheduler from a DB parameter group by setting the parameter `event_scheduler` to ON. For information about creating and modifying a DB parameter group, see [Working with DB parameter groups \(p. 228\)](#).

You can then use the procedures in the following table to enable and configure GoSH. First connect to your MySQL DB instance, then issue the appropriate commands as shown following. For more information, see [Connecting to a DB instance running the MySQL database engine \(p. 840\)](#). For each procedure, type the following:

```
CALL procedure-name;
```

Where *procedure-name* is one of the procedures in the table.

Procedure	Description
<code>mysql.rds_enable_gsh_collector</code>	Enables GoSH to take default snapshots at intervals specified by <code>rds_set_gsh_collector</code> .
<code>mysql.rds_set_gsh_collector</code>	Specifies the interval, in minutes, between snapshots. Default value is 5.
<code>mysql.rds_disable_gsh_collector</code>	Disables snapshots.
<code>mysql.rds_collect_global_status</code>	Takes a snapshot on demand.
<code>mysql.rds_enable_gsh_rotation</code>	Enables rotation of the contents of the <code>mysql.rds_global_status_history</code> table to <code>mysql.rds_global_status_history_old</code> at intervals specified by <code>rds_set_gsh_rotation</code> .
<code>mysql.rds_set_gsh_rotation</code>	Specifies the interval, in days, between table rotations. Default value is 7.
<code>mysql.rds_disable_gsh_rotation</code>	Disables table rotation.
<code>mysql.rds_rotate_global_status_history</code>	Rotates the contents of the <code>mysql.rds_global_status_history</code> table to <code>mysql.rds_global_status_history_old</code> on demand.

When GoSH is running, you can query the tables that it writes to. For example, to query the hit ratio of the Innodb buffer pool, you would issue the following query:

```
select a.collection_end, a.collection_start, ((a.variable_Delta-b.variable_delta)/a.variable_delta)*100 as "HitRatio"
```

```
from mysql.rds_global_status_history as a join mysql.rds_global_status_history as b on
a.collection_end = b.collection_end
where a.variable_name = 'Innodb_buffer_pool_read_requests' and b.variable_name =
'Innodb_buffer_pool_reads'
```

Using Kerberos authentication for MySQL

You can use Kerberos authentication to authenticate users when they connect to your MySQL DB instance. The DB instance works with AWS Directory Service for Microsoft Active Directory (AWS Managed Microsoft AD) to enable Kerberos authentication. When users authenticate with a MySQL DB instance joined to the trusting domain, authentication requests are forwarded. Forwarded requests go to the domain directory that you create with AWS Directory Service.

Keeping all of your credentials in the same directory can save you time and effort. With this approach, you have a centralized place for storing and managing credentials for multiple DB instances. Using a directory can also improve your overall security profile.

Amazon RDS supports Kerberos authentication for MySQL DB instances in the following AWS Regions:

- US East (Ohio)
- US East (N. Virginia)
- US West (N. California)
- US West (Oregon)
- Asia Pacific (Mumbai)
- Asia Pacific (Seoul)
- Asia Pacific (Singapore)
- Asia Pacific (Sydney)
- Asia Pacific (Tokyo)
- Canada (Central)
- Europe (Frankfurt)
- Europe (Ireland)
- Europe (London)
- Europe (Stockholm)
- South America (São Paulo)
- China (Beijing)
- China (Ningxia)

To set up Kerberos authentication for a MySQL DB instance, complete the following general steps, described in more detail later:

1. Use AWS Managed Microsoft AD to create an AWS Managed Microsoft AD directory. You can use the AWS Management Console, the AWS CLI, or the AWS Directory Service to create the directory. For details about doing so, see [Create your AWS Managed Microsoft AD directory](#) in the *AWS Directory Service Administration Guide*.
2. Create an AWS Identity and Access Management (IAM) role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess`. The role allows Amazon RDS to make calls to your directory.

For the role to allow access, the AWS Security Token Service (AWS STS) endpoint must be activated in the AWS Region for your AWS account. AWS STS endpoints are active by default in all AWS Regions, and you can use them without any further actions. For more information, see [Activating and deactivating AWS STS in an AWS Region](#) in the *IAM User Guide*.

3. Create and configure users in the AWS Managed Microsoft AD directory using the Microsoft Active Directory tools. For more information about creating users in your Active Directory, see [Manage users and groups in AWS managed Microsoft AD](#) in the *AWS Directory Service Administration Guide*.
4. Create or modify a MySQL DB instance. If you use either the CLI or RDS API in the create request, specify a domain identifier with the `Domain` parameter. Use the `d-*` identifier that was generated when you created your directory and the name of the role that you created.

If you modify an existing MySQL DB instance to use Kerberos authentication, set the domain and IAM role parameters for the DB instance. Locate the DB instance in the same VPC as the domain directory.

5. Use the Amazon RDS master user credentials to connect to the MySQL DB instance. Create the user in MySQL using the `CREATE USER` clause `IDENTIFIED WITH 'auth_pam'`. Users that you create this way can log in to the MySQL DB instance using Kerberos authentication.

Setting up Kerberos authentication for MySQL DB instances

You use AWS Managed Microsoft AD to set up Kerberos authentication for a MySQL DB instance. To set up Kerberos authentication, you take the following steps.

Step 1: Create a directory using AWS Managed Microsoft AD

AWS Directory Service creates a fully managed Active Directory in the AWS Cloud. When you create an AWS Managed Microsoft AD directory, AWS Directory Service creates two domain controllers and Domain Name System (DNS) servers on your behalf. The directory servers are created in different subnets in a VPC. This redundancy helps make sure that your directory remains accessible even if a failure occurs.

When you create an AWS Managed Microsoft AD directory, AWS Directory Service performs the following tasks on your behalf:

- Sets up an Active Directory within the VPC.
- Creates a directory administrator account with the user name Admin and the specified password. You use this account to manage your directory.

Note

Be sure to save this password. AWS Directory Service doesn't store it. You can reset it, but you can't retrieve it.

- Creates a security group for the directory controllers.

When you launch an AWS Managed Microsoft AD, AWS creates an Organizational Unit (OU) that contains all of your directory's objects. This OU has the NetBIOS name that you typed when you created your directory and is located in the domain root. The domain root is owned and managed by AWS.

The Admin account that was created with your AWS Managed Microsoft AD directory has permissions for the most common administrative activities for your OU:

- Create, update, or delete users
- Add resources to your domain such as file or print servers, and then assign permissions for those resources to users in your OU
- Create additional OUs and containers
- Delegate authority
- Restore deleted objects from the Active Directory Recycle Bin
- Run AD and DNS Windows PowerShell modules on the Active Directory Web Service

The Admin account also has rights to perform the following domain-wide activities:

- Manage DNS configurations (add, remove, or update records, zones, and forwarders)
- View DNS event logs
- View security event logs

To create a directory with AWS Managed Microsoft AD

1. Sign in to the AWS Management Console and open the AWS Directory Service console at <https://console.aws.amazon.com/directoryservicev2/>.
2. In the navigation pane, choose **Directories** and choose **Set up Directory**.
3. Choose **AWS Managed Microsoft AD**. AWS Managed Microsoft AD is the only option that you can currently use with Amazon RDS.
4. Enter the following information:

Directory DNS name

The fully qualified name for the directory, such as `corp.example.com`.

Directory NetBIOS name

The short name for the directory, such as `CORP`.

Directory description

(Optional) A description for the directory.

Admin password

The password for the directory administrator. The directory creation process creates an administrator account with the user name Admin and this password.

The directory administrator password and can't include the word "admin." The password is case-sensitive and must be 8–64 characters in length. It must also contain at least one character from three of the following four categories:

- Lowercase letters (a–z)
- Uppercase letters (A–Z)
- Numbers (0–9)
- Non-alphanumeric characters (~!@#\$%^&*_+=`|\{}{};:"";<>,?./)

Confirm password

The administrator password retyped.

5. Choose **Next**.
6. Enter the following information in the **Networking** section and then choose **Next**:

VPC

The VPC for the directory. Create the MySQL DB instance in this same VPC.

Subnets

Subnets for the directory servers. The two subnets must be in different Availability Zones.

7. Review the directory information and make any necessary changes. When the information is correct, choose **Create directory**.

Step 2: Create the IAM role for use by Amazon RDS

For Amazon RDS to call AWS Directory Service for you, an IAM role that uses the managed IAM policy `AmazonRDSDirectoryServiceAccess` is required. This role allows Amazon RDS to make calls to the AWS Directory Service.

When a DB instance is created using the AWS Management Console and the console user has the `iam:CreateRole` permission, the console creates this role automatically. In this case, the role name is `rds-directoryservice-kerberos-access-role`. Otherwise, you must create the IAM role manually. When you create this IAM role, choose `Directory Service`, and attach the AWS managed policy `AmazonRDSDirectoryServiceAccess` to it.

For more information about creating IAM roles for a service, see [Creating a role to delegate permissions to an AWS service](#) in the *IAM User Guide*.

Note

The IAM role used for Windows Authentication for RDS for Microsoft SQL Server can't be used for RDS for MySQL.

Optionally, you can create policies with the required permissions instead of using the managed IAM policy `AmazonRDSDirectoryServiceAccess`. In this case, the IAM role must have the following IAM trust policy.

```
{
```

```
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "",
            "Effect": "Allow",
            "Principal": {
                "Service": [
                    "directoryservice.rds.amazonaws.com",
                    "rds.amazonaws.com"
                ]
            },
            "Action": "sts:AssumeRole"
        }
    ]
}
```

The role must also have the following IAM role policy.

```
{
    "Version": "2012-10-17",
    "Statement": [
        {
            "Action": [
                "ds:DescribeDirectories",
                "ds:AuthorizeApplication",
                "ds:UnauthorizeApplication",
                "ds:GetAuthorizedApplicationDetails"
            ],
            "Effect": "Allow",
            "Resource": "*"
        }
    ]
}
```

Step 3: Create and configure users

You can create users with the Active Directory Users and Computers tool. This tool is part of the Active Directory Domain Services and Active Directory Lightweight Directory Services tools. Users represent individual people or entities that have access to your directory.

To create users in an AWS Directory Service directory, you must be connected to an Amazon EC2 instance based on Microsoft Windows. This instance must be a member of the AWS Directory Service directory and be logged in as a user that has privileges to create users. For more information, see [Manage users and groups in AWS Managed Microsoft AD](#) in the *AWS Directory Service Administration Guide*.

Step 4: Create or modify a MySQL DB instance

Create or modify a MySQL DB instance for use with your directory. You can use the console, CLI, or RDS API to associate a DB instance with a directory. You can do this in one of the following ways:

- Create a new MySQL DB instance using the console, the [create-db-instance](#) CLI command, or the [CreateDBInstance](#) RDS API operation.

For instructions, see [Creating an Amazon RDS DB instance \(p. 141\)](#).

- Modify an existing MySQL DB instance using the console, the [modify-db-instance](#) CLI command, or the [ModifyDBInstance](#) RDS API operation.

For instructions, see [Modifying an Amazon RDS DB instance \(p. 250\)](#).

- Restore a MySQL DB instance from a DB snapshot using the console, the [restore-db-instance-from-db-snapshot](#) CLI command, or the [RestoreDBInstanceFromDBSnapshot](#) RDS API operation.

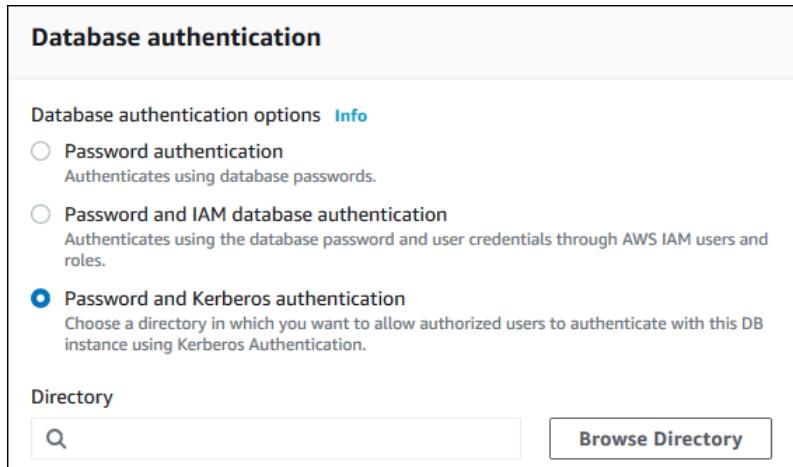

For instructions, see [Restoring from a DB snapshot \(p. 349\)](#).

- Restore a MySQL DB instance to a point-in-time using the console, the [restore-db-instance-to-point-in-time](#) CLI command, or the [RestoreDBInstanceToPointInTime](#) RDS API operation.

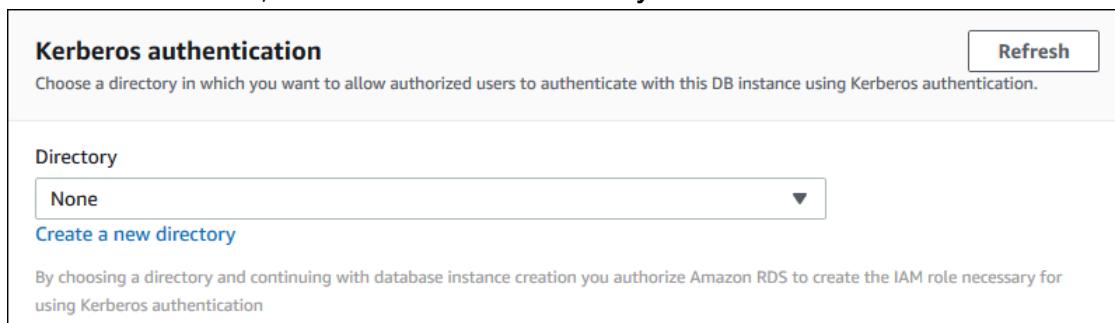

For instructions, see [Restoring a DB instance to a specified time \(p. 389\)](#).

Kerberos authentication is only supported for MySQL DB instances in a VPC. The DB instance can be in the same VPC as the directory, or in a different VPC. The DB instance must use a security group that allows egress within the directory's VPC so the DB instance can communicate with the directory.

When you use the console to create a DB instance, choose **Password and Kerberos authentication** in the **Database authentication** section. Choose **Browse Directory** and then select the directory, or choose **Create a new directory**.

When you use the console to modify or restore a DB instance, choose the directory in the **Kerberos authentication** section, or choose **Create a new directory**.

Use the CLI or RDS API to associate a DB instance with a directory. The following parameters are required for the DB instance to be able to use the domain directory you created:

- For the `--domain` parameter, use the domain identifier ("d-*" identifier) generated when you created the directory.
- For the `--domain-iam-role-name` parameter, use the role you created that uses the managed IAM policy `AmazonRDSdirectoryServiceAccess`.

For example, the following CLI command modifies a DB instance to use a directory.

For Linux, macOS, or Unix:

```
aws rds modify-db-instance \
--db-instance-identifier mydbinstance \
--domain d-ID \
--domain-iam-role-name role-name
```

For Windows:

```
aws rds modify-db-instance ^
--db-instance-identifier mydbinstance ^
--domain d-ID ^
--domain-iam-role-name role-name
```

Important

If you modify a DB instance to enable Kerberos authentication, reboot the DB instance after making the change.

Step 5: Create Kerberos authentication MySQL logins

Use the Amazon RDS master user credentials to connect to the MySQL DB instance as you do any other DB instance. The DB instance is joined to the AWS Managed Microsoft AD domain. Thus, you can provision MySQL logins and users from the Active Directory users in your domain. Database permissions are managed through standard MySQL permissions that are granted to and revoked from these logins.

You can allow an Active Directory user to authenticate with MySQL. To do this, first use the Amazon RDS master user credentials to connect to the MySQL DB instance as with any other DB instance. After you're logged in, create an externally authenticated user with PAM (Pluggable Authentication Modules) in MySQL as shown following.

```
CREATE USER 'testuser'@'%' IDENTIFIED WITH 'auth_pam';
UPDATE mysql.user SET ssl_type = 'any' WHERE ssl_type = '' AND PLUGIN = 'auth_pam' and USER = 'testuser';
FLUSH PRIVILEGES;
```

Replace *testuser* with the user name. Users (both humans and applications) from your domain can now connect to the DB instance from a domain joined client machine using Kerberos authentication.

Important

We strongly recommended that clients use SSL/TLS connections when using PAM authentication. If they don't use SSL/TLS connections, the password might be sent as clear text in some cases.

Managing a DB instance in a domain

You can use the CLI or the RDS API to manage your DB instance and its relationship with your managed Active Directory. For example, you can associate an Active Directory for Kerberos authentication and disassociate an Active Directory to disable Kerberos authentication. You can also move a DB instance to be externally authenticated by one Active Directory to another.

For example, using the Amazon RDS API, you can do the following:

- To reattempt enabling Kerberos authentication for a failed membership, use the `ModifyDBInstance` API operation and specify the current membership's directory ID.
- To update the IAM role name for membership, use the `ModifyDBInstance` API operation and specify the current membership's directory ID and the new IAM role.

- To disable Kerberos authentication on a DB instance, use the `ModifyDBInstance` API operation and specify `none` as the domain parameter.
- To move a DB instance from one domain to another, use the `ModifyDBInstance` API operation and specify the domain identifier of the new domain as the domain parameter.
- To list membership for each DB instance, use the `DescribeDBInstances` API operation.

Understanding domain membership

After you create or modify your DB instance, it becomes a member of the domain. You can view the status of the domain membership for the DB instance by running the `describe-db-instances` CLI command. The status of the DB instance can be one of the following:

- `kerberos-enabled` – The DB instance has Kerberos authentication enabled.
- `enabling-kerberos` – AWS is in the process of enabling Kerberos authentication on this DB instance.
- `pending-enable-kerberos` – The enabling of Kerberos authentication is pending on this DB instance.
- `pending-maintenance-enable-kerberos` – AWS will attempt to enable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `pending-disable-kerberos` – The disabling of Kerberos authentication is pending on this DB instance.
- `pending-maintenance-disable-kerberos` – AWS will attempt to disable Kerberos authentication on the DB instance during the next scheduled maintenance window.
- `enable-kerberos-failed` – A configuration problem has prevented AWS from enabling Kerberos authentication on the DB instance. Check and fix your configuration before reissuing the DB instance `modify` command.
- `disabling-kerberos` – AWS is in the process of disabling Kerberos authentication on this DB instance.

A request to enable Kerberos authentication can fail because of a network connectivity issue or an incorrect IAM role. For example, suppose that you create a DB instance or modify an existing DB instance and the attempt to enable Kerberos authentication fails. If this happens, re-issue the `modify` command or modify the newly created DB instance to join the domain.

Connecting to MySQL with Kerberos authentication

To connect to MySQL with Kerberos authentication, you must log in using the Kerberos authentication type.

To create a database user that you can connect to using Kerberos authentication, use an `IDENTIFIED WITH` clause on the `CREATE USER` statement. For instructions, see [Step 5: Create Kerberos authentication MySQL logins \(p. 945\)](#).

To avoid errors, use the MariaDB `mysql` client. You can download MariaDB software at <https://downloads.mariadb.org/>.

At a command prompt, connect to one of the endpoints associated with your MySQL DB instance. Follow the general procedures in [Connecting to a DB instance running the MySQL database engine \(p. 840\)](#). When you're prompted for the password, enter the Kerberos password associated with that user name.

Restoring a MySQL DB instance and adding it to a domain

You can restore a DB snapshot or complete a point-in-time restore for a MySQL DB instance and then add it to a domain. After the DB instance is restored, modify the DB instance using the process explained in [Step 4: Create or modify a MySQL DB instance \(p. 943\)](#) to add the DB instance to a domain.

Kerberos authentication MySQL limitations

The following limitations apply to Kerberos authentication for MySQL:

- A Managed Active Directory that has been shared with you isn't supported.
- Kerberos authentication is supported for the following Amazon RDS for MySQL versions:
 - Amazon RDS for MySQL version 8.0.13, 8.0.15, and 8.0.16
 - Amazon RDS for MySQL version 5.7.24, 5.7.25, and 5.7.26
- You must reboot the DB instance after enabling the feature.
- The domain name length can't be longer than 61 characters.
- You can't enable Kerberos authentication and IAM authentication at the same time. Choose one authentication method or the other for your MySQL DB instance.
- Don't modify the DB instance port after enabling the feature.
- Don't use Kerberos authentication with read replicas.
- To delete a DB instance with this feature enabled, first disable the feature. To do this, use the `modify-db-instance` CLI command for the DB instance and specify `none` for the `--domain` parameter.

If you use the CLI or RDS API to delete a DB instance with this feature enabled, expect a delay.

Known issues and limitations for MySQL on Amazon RDS

Known issues and limitations for working with MySQL on Amazon RDS are as follows.

Topics

- [Inconsistent InnoDB buffer pool size \(p. 948\)](#)
- [Index merge optimization returns wrong results \(p. 948\)](#)
- [Log file size \(p. 949\)](#)
- [MySQL parameter exceptions for Amazon RDS DB instances \(p. 949\)](#)
- [MySQL file size limits in Amazon RDS \(p. 950\)](#)
- [MySQL Keyring Plugin not supported \(p. 951\)](#)

Inconsistent InnoDB buffer pool size

For MySQL 5.7, there is currently a bug in the way that the InnoDB buffer pool size is managed. MySQL 5.7 might adjust the value of the `innodb_buffer_pool_size` parameter to a large value that can result in the InnoDB buffer pool growing too large and using up too much memory. This effect can cause the MySQL database engine to stop running or can prevent the MySQL database engine from starting. This issue is more common for DB instance classes that have less memory available.

To resolve this issue, set the value of the `innodb_buffer_pool_size` parameter to a multiple of the product of the `innodb_buffer_pool_instances` parameter value and the `innodb_buffer_pool_chunk_size` parameter value. For example, you might set the `innodb_buffer_pool_size` parameter value to a multiple of eight times the product of the `innodb_buffer_pool_instances` and `innodb_buffer_pool_chunk_size` parameter values, as shown in the following example.

```
innodb_buffer_pool_chunk_size = 536870912
innodb_buffer_pool_instances = 4
innodb_buffer_pool_size = (536870912 * 4) * 8 = 17179869184
```

For details on this MySQL 5.7 bug, go to <https://bugs.mysql.com/bug.php?id=79379> in the MySQL documentation.

Index merge optimization returns wrong results

Queries that use index merge optimization might return wrong results due to a bug in the MySQL query optimizer that was introduced in MySQL 5.5.37. When you issue a query against a table with multiple indexes the optimizer scans ranges of rows based on the multiple indexes, but does not merge the results together correctly. For more information on the query optimizer bug, go to <http://bugs.mysql.com/bug.php?id=72745> and <http://bugs.mysql.com/bug.php?id=68194> in the MySQL bug database.

For example, consider a query on a table with two indexes where the search arguments reference the indexed columns.

```
SELECT * FROM table1
WHERE indexed_col1 = 'value1' AND indexed_col2 = 'value2';
```

In this case, the search engine will search both indexes. However, due to the bug, the merged results are incorrect.

To resolve this issue, you can do one of the following:

- Set the `optimizer_switch` parameter to `index_merge=off` in the DB parameter group for your MySQL DB instance. For information on setting DB parameter group parameters, see [Working with DB parameter groups \(p. 228\)](#).
- Upgrade your MySQL DB instance to MySQL version 5.6, 5.7, or 8.0. For more information, see [Upgrading a MySQL DB snapshot \(p. 863\)](#).
- If you cannot upgrade your instance or change the `optimizer_switch` parameter, you can work around the bug by explicitly identifying an index for the query, for example:

```
SELECT * FROM table1
USE INDEX covering_index
WHERE indexed_col1 = 'value1' AND indexed_col2 = 'value2';
```

For more information, go to [Index merge optimization](#).

Log file size

For MySQL, there is a size limit on BLOBS written to the redo log. To account for this limit, ensure that the `innodb_log_file_size` parameter for your MySQL DB instance is 10 times larger than the largest BLOB data size found in your tables, plus the length of other variable length fields (`VARCHAR`, `VARBINARY`, `TEXT`) in the same tables. For information on how to set parameter values, see [Working with DB parameter groups \(p. 228\)](#). For information on the redo log BLOB size limit, go to [Changes in MySQL 5.6.20](#).

MySQL parameter exceptions for Amazon RDS DB instances

Some MySQL parameters require special considerations when used with an Amazon RDS DB instance.

`lower_case_table_names`

Because Amazon RDS uses a case-sensitive file system, setting the value of the `lower_case_table_names` server parameter to 2 ("names stored as given but compared in lowercase") is not supported. The following are the supported values for Amazon RDS for MySQL DB instances:

- 0 ("names stored as given and comparisons are case-sensitive") is supported for all Amazon RDS for MySQL versions.
- 1 ("names stored in lowercase and comparisons are not case-sensitive") is supported for Amazon RDS for MySQL version 5.5, version 5.6, version 5.7, and version 8.0.19 and higher 8.0 versions.

The `lower_case_table_names` parameter should be set as part of a custom DB parameter group before creating a DB instance. You should avoid changing the `lower_case_table_names` parameter for existing database instances because doing so could cause inconsistencies with point-in-time recovery backups and read replica DB instances.

Read replicas should always use the same `lower_case_table_names` parameter value as the source DB instance.

`long_query_time`

You can set the `long_query_time` parameter to a floating point value which allows you to log slow queries to the MySQL slow query log with microsecond resolution. You can set a value such as 0.1

seconds, which would be 100 milliseconds, to help when debugging slow transactions that take less than one second.

MySQL file size limits in Amazon RDS

For MySQL DB instances, the maximum provisioned storage limit constrains the size of a table to a maximum size of 16 TB when using InnoDB file-per-table tablespaces. This limit also constrains the system tablespace to a maximum size of 16 TB. InnoDB file-per-table tablespaces (with tables each in their own tablespace) is set by default for MySQL DB instances.

Note

Some existing DB instances have a lower limit. For example, MySQL DB instances created before April 2014 have a file and table size limit of 2 TB. This 2 TB file size limit also applies to DB instances or read replicas created from DB snapshots taken before April 2014, regardless of when the DB instance was created.

There are advantages and disadvantages to using InnoDB file-per-table tablespaces, depending on your application. To determine the best approach for your application, go to [File-per-table tablespaces](#) in the MySQL documentation.

We don't recommend allowing tables to grow to the maximum file size. In general, a better practice is to partition data into smaller tables, which can improve performance and recovery times.

One option that you can use for breaking a large table up into smaller tables is partitioning. Partitioning distributes portions of your large table into separate files based on rules that you specify. For example, if you store transactions by date, you can create partitioning rules that distribute older transactions into separate files using partitioning. Then periodically, you can archive the historical transaction data that doesn't need to be readily available to your application. For more information, go to [Partitioning](#) in the MySQL documentation.

To determine the file size of a table

- Use the following SQL command to determine if any of your tables are too large and are candidates for partitioning.

```
SELECT TABLE_SCHEMA, TABLE_NAME,
round(((DATA_LENGTH + INDEX_LENGTH) / 1024 / 1024), 2) As "Approximate size (MB)"
FROM information_schema.TABLES
WHERE TABLE_SCHEMA NOT IN ('mysql', 'information_schema', 'performance_schema');
```

To enable InnoDB file-per-table tablespaces

- To enable InnoDB file-per-table tablespaces, set the *innodb_file_per_table* parameter to 1 in the parameter group for the DB instance.

To disable InnoDB file-per-table tablespaces

- To disable InnoDB file-per-table tablespaces, set the *innodb_file_per_table* parameter to 0 in the parameter group for the DB instance.

For information on updating a parameter group, see [Working with DB parameter groups \(p. 228\)](#).

When you have enabled or disabled InnoDB file-per-table tablespaces, you can issue an `ALTER TABLE` command to move a table from the global tablespace to its own tablespace, or from its own tablespace to the global tablespace as shown in the following example:

```
ALTER TABLE table_name ENGINE=InnoDB;
```

MySQL Keyring Plugin not supported

Currently, Amazon RDS for MySQL does not support the MySQL `keyring_aws` Amazon Web Services Keyring Plugin.

MySQL on Amazon RDS SQL reference

This appendix describes system stored procedures that are available for Amazon RDS instances running the MySQL DB engine.

Overview

The following system stored procedures are supported for Amazon RDS DB instances running MySQL.

Replication

- [mysql.rds_set_master_auto_position \(p. 953\)](#)
- [mysql.rds_set_external_master \(p. 954\)](#)
- [mysql.rds_set_external_master_with_delay \(p. 956\)](#)
- [mysql.rds_set_external_master_with_auto_position \(p. 959\)](#)
- [mysql.rds_reset_external_master \(p. 961\)](#)
- [mysql.rds_import_binlog_ssl_material \(p. 962\)](#)
- [mysql.rds_remove_binlog_ssl_material \(p. 963\)](#)
- [mysql.rds_set_source_delay \(p. 964\)](#)
- [mysql.rds_start_replication \(p. 964\)](#)
- [mysql.rds_start_replication_until \(p. 965\)](#)
- [mysql.rds_start_replication_until_gtid \(p. 966\)](#)
- [mysql.rds_stop_replication \(p. 967\)](#)
- [mysql.rds_skip_transaction_with_gtid \(p. 968\)](#)
- [mysql.rds_skip_repl_error \(p. 968\)](#)
- [mysql.rds_next_master_log \(p. 969\)](#)

InnoDB cache warming

- [mysql.rds_innodb_buffer_pool_dump_now \(p. 971\)](#)
- [mysql.rds_innodb_buffer_pool_load_now \(p. 971\)](#)
- [mysql.rds_innodb_buffer_pool_load_abort \(p. 972\)](#)

Managing additional configuration (for example, binlog file retention)

- [mysql.rds_set_configuration \(p. 972\)](#)
- [mysql.rds_show_configuration \(p. 974\)](#)

Ending a session or query

- [mysql.rds_kill \(p. 974\)](#)
- [mysql.rds_kill_query \(p. 975\)](#)

Logging

- [mysql.rds_rotate_general_log \(p. 975\)](#)
- [mysql.rds_rotate_slow_log \(p. 976\)](#)

Managing the global status history

- [mysql.rds_enable_gsh_collector \(p. 976\)](#)
- [mysql.rds_set_gsh_collector \(p. 976\)](#)
- [mysql.rds_disable_gsh_collector \(p. 976\)](#)
- [mysql.rds_collect_global_status_history \(p. 977\)](#)
- [mysql.rds_enable_gsh_rotation \(p. 977\)](#)
- [mysql.rds_set_gsh_rotation \(p. 977\)](#)
- [mysql.rds_disable_gsh_rotation \(p. 977\)](#)
- [mysql.rds_rotate_global_status_history \(p. 978\)](#)

SQL reference conventions

Following, you can find explanations for the conventions that are used to describe the syntax of the system stored procedures and tables described in the SQL reference section.

Character	Description
UPPERCASE	Words in uppercase are keywords.
[]	Square brackets indicate optional arguments.
{ }	Braces indicate that you are required to choose one of the arguments inside the braces.
	Pipes separate arguments that you can choose.
<i>italics</i>	Words in italics indicate placeholders. You must insert the appropriate value in place of the word in italics.
...	An ellipsis indicates that you can repeat the preceding element.
'	Words in single quotes indicate that you must type the quotes.

mysql.rds_set_master_auto_position

Sets the replication mode to be based on either binary log file positions or on global transaction identifiers (GTIDs).

Syntax

```
CALL mysql.rds_set_master_auto_position (
    auto_position_mode
);
```

Parameters

auto_position_mode

A value that indicates whether to use log file position replication or GTID-based replication:

- 0 – Use the replication method based on binary log file position. The default is 0.

- 1 – Use the GTID-based replication method.

Usage notes

The master user must run the `mysql.rds_set_master_auto_position` procedure.

For RDS for MySQL 5.7, this procedure is supported for MySQL 5.7.23 and later MySQL 5.7 versions. This procedure is not supported for RDS for MySQL 5.5, 5.6, or 8.0.

mysql.rds_set_external_master

Configures a MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group \(p. 232\)](#).

Note

You can use the [mysql.rds_set_external_master_with_delay \(p. 956\)](#) stored procedure to configure an external source database instance and delayed replication.

Syntax

```
CALL mysql.rds_set_external_master (
    host_name
    , host_port
    , replication_user_name
    , replication_user_password
    , mysql_binary_log_file_name
    , mysql_binary_log_file_location
    , ssl_encryption
);
```

Parameters

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in `replication_user_name`.

mysql_binary_log_file_name

The name of the binary log on the source database instance that contains the replication information.

mysql_binary_log_file_location

The location in the `mysql_binary_log_file_name` binary log at which replication starts reading the replication information.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

Note

The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

Usage notes

The master user must run the `mysql.rds_set_external_master` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run `mysql.rds_set_external_master`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify `replication_user_name` and `replication_user_password` values that indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

MySQL 5.5, 5.6, and 5.7

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

MySQL 8.0

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED WITH mysql_native_password BY 'password';
```

2. On the external instance of MySQL, grant `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges to your replication user. The following example grants `REPLICATION CLIENT` and `REPLICATION SLAVE` privileges on all databases for the 'repl_user' user for your domain.

MySQL 5.5, 5.6, and 5.7

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com' IDENTIFIED BY 'password';
```

MySQL 8.0

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com';
```

To use encrypted replication, configure source database instance to use SSL connections. Also, import the certificate authority certificate, client certificate, and client key into the DB instance or DB cluster using the [mysql.rds_import_binlog_ssl_material \(p. 962\)](#) procedure.

Note

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see [Working with read replicas \(p. 278\)](#).

After calling `mysql.rds_set_external_master` to configure an Amazon RDS DB instance as a read replica, you can call [mysql.rds_start_replication \(p. 964\)](#) on the read replica to start the replication process. You can call [mysql.rds_reset_external_master \(p. 961\)](#) to remove the read replica configuration.

When `mysql.rds_set_external_master` is called, Amazon RDS records the time, user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS.

```
call mysql.rds_set_external_master(
  'Externaldb.some.com',
  3306,
  'repl_user',
  'password',
  'mysql-bin-changelog.0777',
  120,
  0);
```

mysql.rds_set_external_master_with_delay

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS and configures delayed replication.

Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group \(p. 232\)](#).

Syntax

```
CALL mysql.rds_set_external_master_with_delay (
  host_name
, host_port
, replication_user_name
, replication_user_password
, mysql_binary_log_file_name
, mysql_binary_log_file_location
, ssl_encryption
, delay
);
```

Parameters

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS that will become the source database instance.

host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes SSH port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in `replication_user_name`.

mysql_binary_log_file_name

The name of the binary log on the source database instance contains the replication information.

mysql_binary_log_file_location

The location in the `mysql_binary_log_file_name` binary log at which replication will start reading the replication information.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

Note

The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86400 seconds).

Usage notes

The master user must run the `mysql.rds_set_external_master_with_delay` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

Before you run `mysql.rds_set_external_master_with_delay`, you must configure the instance of MySQL running external to Amazon RDS to be a source database instance. To connect to the MySQL instance running external to Amazon RDS, you must specify values for `replication_user_name` and `replication_user_password`. These values must indicate a replication user that has `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the external instance of MySQL.

To configure an external instance of MySQL as a source database instance

1. Using the MySQL client of your choice, connect to the external instance of MySQL and create a user account to be used for replication. The following is an example.

```
CREATE USER 'repl_user'@'mydomain.com' IDENTIFIED BY 'SomePassW0rd'
```

2. On the external instance of MySQL, grant REPLICATION CLIENT and REPLICATION SLAVE privileges to your replication user. The following example grants REPLICATION CLIENT and REPLICATION SLAVE privileges on all databases for the 'repl_user' user for your domain.

```
GRANT REPLICATION CLIENT, REPLICATION SLAVE ON *.* TO 'repl_user'@'mydomain.com'  
IDENTIFIED BY 'SomePassWord'
```

For more information, see [Replication with a MySQL or MariaDB instance running external to Amazon RDS \(p. 914\)](#).

Note

We recommend that you use read replicas to manage replication between two Amazon RDS DB instances when possible. When you do so, we recommend that you use only this and other replication-related stored procedures. These practices enable more complex replication topologies between Amazon RDS DB instances. We offer these stored procedures primarily to enable replication with MySQL instances running external to Amazon RDS. For information about managing replication between Amazon RDS DB instances, see [Working with read replicas \(p. 278\)](#).

After calling `mysql.rds_set_external_master_with_delay` to configure an Amazon RDS DB instance as a read replica, you can call [mysql.rds_start_replication \(p. 964\)](#) on the read replica to start the replication process. You can call [mysql.rds_reset_external_master \(p. 961\)](#) to remove the read replica configuration.

When you call `mysql.rds_set_external_master_with_delay`, Amazon RDS records the time, the user, and an action of `set master` in the `mysql.rds_history` and `mysql.rds_replication_status` tables.

For disaster recovery, you can use this procedure with the [mysql.rds_start_replication_until \(p. 965\)](#) or [mysql.rds_start_replication_until_gtid \(p. 966\)](#) stored procedure. To roll forward changes to a delayed read replica to the time just before a disaster, you can run the `mysql.rds_set_external_master_with_delay` procedure. After the `mysql.rds_start_replication_until` procedure stops replication, you can promote the read replica to be the new primary DB instance by using the instructions in [Promoting a read replica to be a standalone DB instance \(p. 285\)](#).

To use the `mysql.rds_start_replication_until_gtid` procedure, GTID-based replication must be enabled. To skip a specific GTID-based transaction that is known to cause disaster, you can use the [mysql.rds_skip_transaction_with_gtid \(p. 968\)](#) stored procedure. For more information about working with GTID-based replication, see [Using GTID-based replication for RDS for MySQL \(p. 910\)](#).

The `mysql.rds_set_external_master_with_delay` procedure is available in these versions of RDS for MySQL:

- MySQL 5.6.40 and later 5.6 versions
- MySQL 5.7.22 and later 5.7 versions

Examples

When run on a MySQL DB instance, the following example configures the DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. It sets the minimum replication delay to one hour (3,600 seconds) on the MySQL DB instance. A change from the MySQL source database instance running external to Amazon RDS is not applied on the MySQL DB instance read replica for at least one hour.

```
call mysql.rds_set_external_master_with_delay(
    'Externaldb.some.com',
    3306,
    'repl_user',
    'SomePassWOrd',
    'mysql-bin-changelog.000777',
    120,
    0,
    3600);
```

mysql.rds_set_external_master_with_auto_position

Configures an RDS for MySQL DB instance to be a read replica of an instance of MySQL running external to Amazon RDS. This procedure also configures delayed replication and replication based on global transaction identifiers (GTIDs).

Important

To run this procedure, `autocommit` must be enabled. To enable it, set the `autocommit` parameter to 1. For information about modifying parameters, see [Modifying parameters in a DB parameter group \(p. 232\)](#).

Syntax

```
CALL mysql.rds_set_external_master_with_auto_position (
    host_name
    , host_port
    , replication_user_name
    , replication_user_password
    , ssl_encryption
    , delay
);
```

Parameters

host_name

The host name or IP address of the MySQL instance running external to Amazon RDS to become the source database instance.

host_port

The port used by the MySQL instance running external to Amazon RDS to be configured as the source database instance. If your network configuration includes Secure Shell (SSH) port replication that converts the port number, specify the port number that is exposed by SSH.

replication_user_name

The ID of a user with `REPLICATION CLIENT` and `REPLICATION SLAVE` permissions on the MySQL instance running external to Amazon RDS. We recommend that you provide an account that is used solely for replication with the external instance.

replication_user_password

The password of the user ID specified in `replication_user_name`.

ssl_encryption

A value that specifies whether Secure Socket Layer (SSL) encryption is used on the replication connection. 1 specifies to use SSL encryption, 0 specifies to not use encryption. The default is 0.

Note

The `MASTER_SSL_VERIFY_SERVER_CERT` option isn't supported. This option is set to 0, which means that the connection is encrypted, but the certificates aren't verified.

delay

The minimum number of seconds to delay replication from source database instance.

The limit for this parameter is one day (86,400 seconds).

Usage notes

The master user must run the `mysql.rds_set_external_master_with_auto_position` procedure. This procedure must be run on the MySQL DB instance to be configured as the read replica of a MySQL instance running external to Amazon RDS.

For RDS for MySQL 5.7, this procedure is supported for MySQL 5.7.23 and later MySQL 5.7 versions. This procedure is not supported for RDS for MySQL 5.5, 5.6, or 8.0.
